There is, however, a reluctance on the part of capitalists in London and elsewhere to venture their money in the neighbourhood of India, Ceylon, and Java where so many hundreds of thousands

of pounds have been lost over coffee in recent years. This is only natural, but if they could only understand the difference in climate, and the effect of that difference on the pests which have destroyed the coffee in the countries named above there can be little doubt that their present diffidence would be largely dissipated—if not altogether overcome. Anyone who has been unfortunate enough to have had the opportunity of observing the attacks of leaf disease must have noticed that it is the extremes of climate which mostly favour its attacks upon the coffee bush. A long wet season—or a long dry season—seems equally to assist the spread of the fungus, and the occurrence of storms or the blast of a strong wind for a day or two, occasion a development of the disease which is often extremely virulent. As regards Perak especially—such extremes of climate are usually altogether unknown—there is no clearly defined dry and wet season, for the monsoons have generally but a moderate effect on the climate of Malaya. It so happens (most unfortunately for the extension of coffee cultivation in Perak) that the drought, which during the last year has affected all the region from China to Afghanistan, was also felt in an unprecedented degree in Perak—and has been followed very naturally by an equally unprecedented quantity of rain. There is only one plantation of Arabian coffee of any extent in Perak—and the Government has of late years abandoned the experimental gardens—in one at any rate of which the coffee was doing well. The coffee estate was planted by an old sea captain—a German—who probably knew no more of coffee cultivation than the writer of this knows of navigation—perhaps not so much. When he made up his mind to leave the country and retire to Anstralia the Government of Perak resumed possession of the estate, and when it was taken up by its present owners the coffee was grown up in lalang (lulak) grass and chena growth to such an extent that option was given the new proprietors to abandon it if they chose and go on with new land. Under the management—or want of management—of the late owner, the weeds had been allowed to destroy all the lower primaries of the trees—and four-fifths of the are now "beyond trees"—the only branches left being on what has been at one time a sucker sprout from the top of the stems of the trees, which originally seen to have been topped very high. As may easily be imagined by anyone who has worked on the old estates before the era of railways and abundant labour—these trees do not present any very graceful form at any time as no systematic method of pruning can be adopted. When the party of Ceylon men recently visited Perak the old coffee had not had time to recover from the effect of the drought—and consequent attack of leaf disease, which, added to a good crop and an insufficient supply of labour, had rendered the trees very "sticky" and naturally induced a bad impression on the minds of the visitors. The young coffee, at an elevation of over 2,000 feet, was however in beautiful trim—and taking it all round no better plants for their age have ever been seen in Ceylon or anywhere else. The progress made during the past eighteen months was everything that could be desired, and the coming blossoming season will produce a fine crop. The four year old field is very fine, but although the drought has had no effect whatever up at that high elevation, the labour difficulty had made itself apparent and the want of handling and pruning had induced a matted condition of the branches which told unfortunately against the appearance of the trees. The first coffee seen on entering the estate is the old illused field first planted, and it is the last through which the

visitor passes on leaving, so that he is apt to go away with the first and last impression on his mind that after all Arabian coffee is not the thing in which to invest his capital. The next place he sees is the only Liberian coffee estate of any extent in Perak some 3½ years old with younger fields. Here he finds everything flourishing, no sign of leaf disease, abundance of labour on the estate, and a very fine crop on the trees, in fact so much crop that it is a moot question whether it would not be advisable to remove some of it in case the trees may not be able to mature it all and may suffer irretrievably before it is picked. No wonder then that the visitor who has not seen either of the properties before, should incline to invest in Liberian rather than in Arabian coffee. Had he however visited the two estates eighteen months previously he would have found the conditions of each entirely reversed—the Arabian was flourishing, the Liberian suffering from want of labour, and looking very poor.

The position at the present time is in favour of the extension of Liberian cultivation, whilst the more valuable and the more easily manipulated Arabian is neglected. In regard to green bug, as far as may be judged from the very small amount of experience of it and the information available, the constant recurrence of moderate showers causes the insect to die and turn mouldy as happens during the wet weather in Ceylon. The bug has been seen on the Arabian coffee in its early stages, but disappeared within a few weeks without doing any damage. On the other hand in the hotter climate and poorer soil of a certain Liberian coffee estate in Johore, that effect of the green bug was very similar to the so widely experienced in Ceylon, and in the midst of a field of generally flourishing Liberian trees here and there some were to be found entirely denuded of leaf and crop. In Selangor again, on the older Liberian coffee, the bug was apparently causing considerable alarm to the proprietors some eighteen months ago as lime was being applied to the leaves by way of a remedy. It may be mentioned here that a very lively colony of green bug on a guava tree in the middle of the town of Penang disappeared almost entirely on the advent of a few heavy showers, the insects moulded away in a few days. Another reason why Liberian coffee is favoured in the Straits just now in preference to the other and more valuable variety, is that Messrs. Hill and Rathborne have allowed the Perak Government to publish the figures showing the returns of crop produced by their little estate—some of them hardly more than gardens in size—in Selangor and Sungai Ujong. These returns show very fine results—so much so that their correctness was challenged by someone whose experience had tended the other way, but were proved to be correct, with the admission that the extra yield had been brought about by the use of manure—though the trees were quite young. Now the figures for the production of Arabian coffee have not been given to the public, they are not published by the Perak Government as these for the Liberian coffee have, and consequently no one except those interested, or who have made the inquiry, know how remunerative the cultivation is, especially with the European market in its present state. It is to be hoped that statistics of the Arabian crops will be forthcoming for the information of the public, and in the meantime it is authoritatively stated that as much as 10 cwt. per acre has been gathered from the field of old coffee where in its prime. The appearance of the young coffee now warrants the confidence now felt in its bearing capabilities, and the sample is as good as any high-grown plantation grown in Ceylon, where by the way the "parchment" is

sent from Perak to be cured and shipped. Another blow has been aimed at the extension of Arabian coffee cultivation in the Straits by (presumably) the Director of the Botanical Gardens in Singapore in the Agricultural Bulletin of the Malay Peninsula for April 1891. He says, "I do not think Arabian coffee can ever be successfully cultivated in the Straits Settlements." It seems very liable to produce "brush," that is to say abnormal flowers with minute green irregular sepals and petals, no stamens, and the petals very small and apparently effete. I imagine this is due (to the permanent dampness of the climate, and absence of any period of rest from growth.) "Brush," instead of fertile productive blossom, is very well-known to all Ceylon planters, more especially occurring on the higher estates in wet seasons. This indictment against Arabian coffee is a very serious matter, coming as it does *ex cathedra*, and one that cannot be lightly disregarded. However, it may be in other parts of the Straits Settlements, and the Director's opinion may be presumed to include the protected native states, it is satisfactory to learn that the only planter of any experience in Perak regards the statement as by no means applying to Perak; in fact it is denounced as "absurd." He writes, "that Arabian coffee in this country (Perak) produces and will continue to produce as good crops as it did in Ceylon, is an established fact. The old coffee on this place has given its 10 cwt. an acre, so I think that goes a long way towards refuting Mr. Ridley's statement that blossom on coffee Arabica goes to brush instead of fruitifying, owing to the permanent dampness of the climate." Our only risk here—as in Ceylon—is that a very heavy fall of rain may take place just when the blossom is fully out, and so destroy the pollen on the well developed flowers." In Ceylon such a catastrophe as is here alluded to was by no means an uncommon occurrence, as it is the rain, supervening on a long spell of hot weather, which usually brings out the blossoms, but such falls of rain are exceedingly unusual in Perak, and the attendant risk is small compared with that incurred by planters in the spicy island. The writer goes on to ask the pertinent question "what experience has the director of coffee blossoms in Perak—and from what data does he make the assertion—or rather found his opinion?" The result of his (the planter's) experience of the country is, that the statement about brush is "absurd" and "rubbish," and he hoped (the director) would be able to visit Perak in January and February and see the blossoms for himself.

All this tends to prove that coffee planting in Perak will succeed as well as it formerly did in Ceylon—so far at any rate as any climatic influences are concerned; all agricultural pursuits are subject to risks—in more or less degree—in all parts of the world.

It may be as well to close this article with a rough estimate of profit on investment in Arabian coffee. It must be borne in mind that whether land is taken up on the system of an annual rental, or whether the land is purchased outright by the payment of what the Perak Government has chosen to call a "premium," no actual payment need be made for two years from commencement of the work, and indeed so anxious are the authorities that a beginning should be bona-fide made, and ample proof afforded of its being a profitable investment, that even greater facilities would be afforded to those who will at once take up land in the State.

Leaving ample margin for all contingencies and adding some 10 to 15 per cent to the current

estimates given by practical men of experience on the spot, Arabian coffee can be brought into bearing for about \$200 per acre; but to make the matter absolutely certain, so far as such matters can be certain, make it £36 sterling. With ordinary luck the third year's crop should pay all its expenses, and from the fourth year with an annual crop of \$6 per acre, at current rates for such coffee as would be produced at 2 000 to 3,000 feet elevation and costing £15 per annum for production, say 50s per cwt., there would remain a clear profit of £15 per acre, or nearly 50 per cent on the capital outlay. With crops on young coffee, 5 to 10 years of age of 8 to 10 cwt. an acre, the results would be immense, and there is no reason apparent at this time why coffee in Perak should not produce such crops as coffee in Ceylon, India and Java has already done. In four years Arabian coffee may be expected to cover the ground and to be in full bearing, producing a bean, which properly cured and shipped would fetch the extreme rates ruling in the markets of the world. Liberian coffee, on the other hand, takes seven to eight years to come into full bearing and to cover the ground, a large proportion of which in the meantime has to be kept clean and gives no return to the planter. The position of the estates in the hot steamy lowcountry naturally causes the weeds to grow up much faster than on the hills, and consequently the estate is more expensive to weed, and a larger extent of land has to be gone over for a lengthened period than in the cultivation of the other variety. Again the carriage of the cherry coffee on the heads of the coolies for considerable distances is always a matter giving trouble on coffee estates, and whereas 2½ bushels of Arabian cherry give one bushel of parchment, it requires no less than five bushels of Liberian cherry to turn out one of parchment, thus just doubling the weight that has to be carried about the estate—and doubling the trouble and expense of its transport. After all, when the coffee is put on the home markets, Liberian fetches some 15 to 20 shillings per cwt. less than the Arabian. The difference has of late not been so marked simply because there has been little or none of the East Indian coffee to compete with Liberian, the value of the latter of course being altogether abnormal. Liberian has seldom or never touched the round 100 shillings per cwt. whilst high grown Arabica has gone as high as 150s, and good ordinary has ruled 110s to 120s for months at a time. There is no getting out of the fact that the Arabian variety is the more valuable and more easily manipulated of the two varieties, and in Perak the numerous roads already made and the railways, completed and in course of construction, facilitate the opening up of the jungle. The labour supply just now is comparatively large, in consequence of the scarcity of food in India and the depression in the tobacco industry in Sumatra.

RETURNS FROM RICE CULTURE IN CEYLON.

As Sir Arthur Havelock, in his speech at the Agricultural College Prize-giving, expressed so pessimistic a view of the returns from paddy culture in this island, we would draw His Excellency's particular attention to the astounding statement made by a very competent authority elsewhere. So badly is paddy preserved (or so unripe is much of it when harvested) and so little attention is paid to the selection of seed generally, that out of one, two or three bushels sown, according to quality of soil, only one-fourth of a bushel, as a maximum, ever germinates and results in grain-bearing plants. When

to seed so inferior as is thus indicated, careless and unscientific cultivation is added, we need not wonder at poor returns obtained, but we may well protest against impeachment on this account of our natural conditions of soil, irrigation water and climate. In all the rice culture we saw in Java the seeds were germinated in nurseries and planted out into the fields in regular rows. Here such a system is exceptional, while what is called ploughing is really the mere stirring of a few inches of water-saturated mud. The advantages of superior ploughs would be that the land could be ploughed and pulverised when dry—subsoil being stirred without being brought to the surface. This and careful selection of seed would prevent waste of grain, now so enormous, while waste of water would also be prevented, much to the improvement of the grain produced. The impression left on our mind by this latest contribution to the literature of paddy culture is, that where poor returns are the rule, it is not, in most cases soil and climate which are at fault, but perfunctory husbandry.

WASTE IN THE USE OF BUILDING MATERIAL.

Our attention has been directed to the unscientific way in which our native builders often dispose their material in the works of construction undertaken by them. Amongst the people of this colony the study of architecture, not alone as an art but as a practical matter, is, as yet, altogether unknown. It may be said, indeed, that as regards the first of these two aspects we have no architecture at all. The taste shown in the design of the ancient monuments left to us as the work of a bygone age no longer survives, and an art which must at one time have flourished in this island in a high degree no longer exists among us. But it is to the second aspect, that which most concerns us economically, that we would more especially direct attention. It cannot be said that in those ancient works to which we have referred there is evidence of such a disposition of material as would justify us in the assumption that the strength of its many varied forms had been the subject of intelligent consideration. The skill in architectural construction which distinguished the Arab builders, and which enabled them to so erect those light and graceful domes and the towering obelisks which form so essential a feature of Indian architecture, was apparently unknown to our own earlier designers. All their work, like that of the ancient Egyptians, was of so massive a character that they never cared, it would seem, to closely adapt their disposition of material to the exact requirements they had to provide for. Like the Egyptians, it may be said that most of their constructive work was monolithic. They wedged out huge masses of stone, and applied them indiscriminately to support both great and trifling weights. Much of this tendency remains to the present day, and we think that in our schools for technical education no branch of constructive art could better be studied than the adaptation of means to their ends, the study, in a word, both of the strength of materials and of the strains to which they become subject under the many different conditions of their application. It is from the want of this knowledge, we feel sure, that so much of the waste of building material that is observable in all modern works of native construction is due. Nor can we exempt altogether our own Public Works Department from sharing in some degree in the same charge. Many of the officers of that department, until re-

cently, at least, were untrained in the knowledge which would teach them how material may be most economically applied; and in many of our public structures there may, we are told, be observed instances of the misapplication of both masonry and timber work. Such remarks do not, of course, apply to our noble Museum and similar structures. But it is mainly to the ignorance on this subject shown by our native builders that we would desire to draw the attention of those who may hereafter be charged with tuition in our technical schools. We much fear that the tendency of these will be—as it was for many years in the schools at South Kensington and elsewhere at home—to confine instruction mainly to ornamental design. Now in an eastern country like this we can have no desire to see European art grafted upon the technicalities of Oriental design. Nothing can exceed the latter in beauty, and if any attempt be made to give the taste which seems naturally inherent in orientals a hand towards the ornamental designs of the European schools, the result will probably be only to produce a hasty effect which will be anything but pleasing. Far wiser will it be for the course of instruction to be in the direction of teaching our natives how to apply their material without waste: to learn how to proportion the support to the load. How constantly do we see the walls of houses made of undiminished thickness throughout, when the weight of the roofing these have to uphold is distributed over a few points only. Were it the custom to leave house walls in this country fully exposed to the sun or weather, there would not be so much to urge against this universal unnecessary thickness. In Europe such a method is followed to keep the interior of dwellings either warm or cool, to prevent the interiors becoming readily subject to exterior influence. But in the East nearly all house walls are sheltered by verandahs, and consequently nearly half the work put into our walls is wasted. Then, again, in the timber of our roofs and verandahs how constantly may we observe rafters either so slight as to bend under the strain of the tiles they carry, or else the employment of scantlings adequate to carry nearly three times the weight they are ever likely to be subject to. In the first case there is wasteful application because the life of such work must be short; and in the second there is equal waste because less than half the material would have sufficed. The instance cited will furnish the key to the matter to which we think the attention of those who may direct technical education in Ceylon should be specially directed. The A B C of such education must not be neglected by too exclusive a devotion to the cultivation of an artistic taste which may only result in spoiling the inborn disposition of Orientals to ornate design. Teaching which will enable its recipients to perform in the best possible manner the practical operations of every-day life in masonry, carpentry, turnery and engineering is what ought to be mainly imparted.

NOTES ON PRODUCE AND FINANCE

LAST WEEK'S TEA SALES.—Again there has been some abridgment from the excessively heavy supplies of Indian tea, says the *Grocer*, put forward during November, the total quantity brought to auction this week, though still large, not having more than equalled 36,230 packages which met a livelier demand than of late, and have nearly all been realised at full or rather better prices. Almost each day has witnessed an improvement somewhere in the tone of the public sales, and whilst the lower grades, which are 1½d. to 2d. per lb. cheaper

than at this time last year, have been only slightly hardening up in value, the preferable and finer qualities above 10d. and 1s. per lb. forming the smaller proportion of the aggregate supply, have commanded a tangible advance on the irregular quotations recently current. The latest advices from Calcutta, to Nov. 18, report that on the 13th inst. 11,650 chests were sold by auction. Good qualities are still in demand, and occasionally show a slight advance in price, but thin sorts are steady at about last week's prices. The imports into London during the week have been, per Bengal, 1,634,300 lb., and Nubia, 416,600 lb. A revival of demand for Ceylon tea has taken place this week, and prices are firm. Finer grades have been wanted at extreme rates, and though some low figures were recorded for the common kinds, there were a few cases where better values were realised. It is probable that supplies will be increasing soon, and it depends much upon the quality how prices will rule. A few estates lately have sent forward teas of improved quality. Arrivals at this port have been limited, comprising only the Victoria, 336,500 lb., and the Bengal, 229,500 lb. There has been a further falling-off in the quantities of Indian tea offered, says the *Produce Markets Review* and a much firmer tendency has developed in most grades. The demand generally continues extremely good for his period of the year, which is entirely attributable to the increasing consumption, and the good value offering in Indian growths. Although the stock at the end of last month was considerably in excess of the same time last year, at the present rate of consumption the supply will probably not prove excessive. It is difficult to forecast the course of prices during the next few weeks, as the supply in January bids fair to be heavy, but the present tendency of the market certainly points towards the conclusion that the lowest prices have been touched. Although the demand for Ceylon teas has rather fallen off, the smallness of the quantities brought forward on the one hand, and anticipations of a better demand after Christmas on the other, have sufficed to raise prices for almost all grades. The commonest kinds have been the least affected, and cannot be said to be dearer, but Pekocs at from 8d and upwards show a rise of from ½d to ¾d, while really fine liquoring teas command ¾d to 1d more than a month since. Broken teas of all grades are in good demand. The general quality of the supplies has, unfortunately, shown no improvement; hence the extreme prices realised for a few of the best parcels.

COFFEE MIXTURES.—At the County Magistrates' Court, Liverpool, on Monday, the question as to the meaning of the term "French coffee," as it is understood by the trade and by the public, arose out of the prosecution of a grocer for having sold to a person sent by the police a mixture containing 65 per cent of chicory. The evidence showed that there was no attempt to deceive, but that on the contrary the mixture was plainly labelled as such, and that, moreover, the purchaser was distinctly told the nature of the compound. The bench dismissed the case, but inflicted a fine of 20s and cost in another instance wherein the nature of the articles had not been thoroughly explained to the purchaser.

THE UNITED STATES AND THE WEST INDIES.—We learn from Washington that a commercial agreement has been arrived at with the British West Indies and British Guiana, whereby in return for the continued free introduction into the United States of sugar and coffee those colonies agree not only to enlarge greatly the free list of their customs tariff, but to make decided reductions in the duties imposed on the products of the United States.—*H. and C. Mail*, Dec. 18th.

It must be gratifying to our planters to find that Ceylon and Indian tea is rapidly driving the Chinese article out of the market in the Australasian Colonies. Ceylon tea particularly is rising in favour at the Antipodes, and the Indian producers have now much to fear from the competition in the Ceylon quarter. Before long it seems probable that both John Chinaman and his staple export will be practically excluded from Australasian shores.—*Colonies and India*, Dec. 26th.

COOLIES FOR ASSAM.

We have already commented on the great and bitter cry of the Assam planter that the supply of labour is daily growing not only more scanty in amount but inferior in quality. This is a matter which not only affects the great tea industry, and, indirectly, the Government and population of Assam; the question is also interesting to us who live in Northern and Western India. Assam affords an ample outlet for our surplus population; it behoves us to inquire with some minuteness why our landless labourers are beginning to look askance on tea garden work, and can only be persuaded to emigrate by the unholy persuasions of the *arkati* and the crimp. The present system of recruiting is admittedly open to serious abuse of a kind which it is extremely difficult to check. And now we are told that this evil system has not even the recommendation of success, and that the supply of coolies is rapidly falling off. To what causes is the unpopularity of tea garden labour due?

It can hardly be said that the drain has been so severe as to have taken off all the people who are so poor as to need a refuge in temporary exile. A good deal has been said in some quarters about the expense and length of the journey to Assam. It has been hinted that when once Assam is connected with the rest of India by railway the labour question will solve itself. This seems somewhat doubtful. Every cold weather swarm of men go to Assam from Nepal, from these Provinces and from Tirhoot, to work on the Government roads, or to sell droves of plough cattle or buffaloes. Most of these march by land, or, taking rail to Dhubri, walk the rest of the way. Even those who indulge in the luxury of a railway and steamer journey to Dhubri can make their way from Chapra or Munzaffarpur to Dibrugarh at a cost of from Rs 12 to Rs 14. The journey will occupy less than three weeks. Those of them who do earthwork on the roads reap a handsome harvest. The rate for earthwork paid by the Public Works Department in Assam is liberal, Rs 4.8 or Rs 5 per 1,000 cubic feet, we understand. A road-working coolie can easily do his 2,500 cubic feet in a month, and in the six months of the dry weather may easily lay by his Rs 60 or Rs 60. Of this he will spend some Rs 12 on the return journey, and the rest, in so short a period as six months, is pure gain. Here is an annual exodus which is purely voluntary. It is supervised by no Government agency. It is unattended by the wiles and oppressions of *arkatis*, and as an instance of successful and useful migration well deserves record. It proves that the natives of N. W. India will gladly travel to Assam at their own risk and expense, so that the labour they have to perform is done in the cold weather, and is sufficiently well paid to leave a margin for saving.

But the planter wants his coolies to labour all the year through; and chiefly in the rainy months, which are especially trying to unacclimatised inhabitants of drier parts of India. Even if wages as high as those earned by road menders were to be had on tea gardens (and in the case of old and trained coolies wages as good, or nearly as good as there may be earned) it is probable that coolies from Upper India are not easily persuaded to remain in Assam throughout successive rainy seasons, until they are acclimatised and really useful. Hence the enormous expense of exporting labour, and the great annual loss by desertion and non-renewal of coolie agreements to which we have already drawn attention. Wherefore the *arkati* steps in, and by blandishments, promises and other persuasions inveigles the coolie to Dhubri and there induces him to enter into an agreement to labour for five years. The result in many cases is entirely for the coolie's benefit. Often he saves money during the term of his agreement, and on its expiry settles down to cultivation in a little clearing in grass jungle, a much more prosperous and contented being than he was in his native abode. But while a voluntary migration automatically selects the best men who are frugal, abstemious and hard-working, the *arkati* finds his victims chiefly among the waifs and strays of rural life. He picks up drunkards and loafers among the men and women of

loose life among recruits of the other sex. It is small wonder that the impatient planter complains that the expense of importing such labour is never recouped, and finds the Labour Law itself ineffectual as a means of getting an honest day's work out of his labourers. It is perhaps astonishing that the average rate of wage paid to tea garden labour should be so high as it is. The present system of recruitment then is attended by many inevitable disappointments and dangers. It is extremely expensive, and it must not be forgotten that the Labour Law itself cannot be administered without expense. The difficulty is to suggest a remedy. That *arkatis* and reemigrants should make a profit by supplying coolies is itself a great evil. How are planters to replace the *arkati* by some less suspicious agency? Can the Government do anything to aid them in the enterprise? It is to the interest of Government to supply easy means of migration from the overstocked provinces of India; it is to its interest that the tea industry should flourish and reclaim the waste places of Assam, and that time expired coolies should open out its jungles. At present Government takes upon itself to look after the welfare of the labourers on tea gardens, and inspectors of labourers are legally empowered to see that tasks are not excessive and that all labourers are provided with the means of earning a sufficient livelihood. Can it not go further and take up the business of an Emigration Agency?

Before it could do so, it would be necessary to make sure that the conditions of labour in Assam were, or could be made, always and invariably better than in the districts of recruitment. It would probably be necessary to strengthen the staff of inspectors, and to raise the statute minimum of wages. Registration offices would be opened, at which coolies should bind themselves to labour in Assam for a term of years. The coolies might then be forwarded to Assam in charge of Government officials and despatched to the different gardens through the inspectors concerned. Any garden in which coolies were ill-treated or ill-paid might be refused a further supply of labour. The bare expenses of travel might be advanced by Government and recouped, as are other such advances, under Act I. of 1882. It may be said that such a scheme is an unwarranted interference with private enterprise. But no one except the *arkatis* themselves, certainly not the coolie or his employer, is likely to resent an interference with the *arkati's* business. If Government were once assured that tea garden life in Assam was really a change for the better for emigrants from other parts of India, it could easily and by the most legitimate means make these advantages known. It could assure the intending emigrant that he would be carefully looked after, and that if he were ill-treated or ill-paid he would be given the option of returning to his home or settling on his own account in Assam.

The suggestion has many obvious drawbacks, which we will leave to others to discuss. Planters themselves admit that the *arkati* is a crying evil, and must be put down at all risks. It is clear that Assam is not yet ripe for free migration, and would probably not be not so even if the future railway were an existing fact. Attempts to organise superior agencies to compete with the *arkatis* seem destined to fail. The *arkati's* methods, if objectionable, are economical. It is quite possible, however, that the *arkati* is a maligned individual, and that natural selection has evolved the fittest person for the task of recruiting coolies. Even in that case the suggestion will have done no harm if it tends to whitewash a misunderstood and necessary individual. But it is a tenebrous subject, especially to minds unacquainted with Assam, and the man who throws real light upon it will be a public benefactor.

One other suggestion occurs to us, which we beg not to be taken entirely in jest. There may yet arise a Cook or a Gago who will personally conduct coolie tourists to the Tom Tiddler's ground of Assam. But that presupposes a happy time when coolies shall be as anxious to travel cheaply and expeditiously to Assam, as pilgrims who seek Mecca. Why does not a Cook arise, and sweep the mob of *arkatis* off the earth. Rumour

has taught us to regard the *arkati*, perhaps unjustly,

"Liko stabled wolves, or tigers at their prey,
Doing abhorred rites to Hecate

In their obscured banquets of inmost hewers."

Is it really true that they have "many baits, and guileful spells t' inveigle and invito th' unwary sero of them that pass unweaving by the way." We almost wonder that a Commission, with Mr. Cook's local agent for chairman, has not been appointed to sit on the *arkati*. Then we should probably hear the *arkati*'s view of the matter.—*Pioneer*.

[There is much in the above which will be of special interest to the tea planters of Ceylon in the present crisis.—ED. T. A.]

AGRICULTURE IN SIAM.

In the Consular report on the trade of Siam during the past year, Mr. Beckett gives an interesting description of the mode in which agricultural operations are carried on in that country.

The system of agriculture, he says, is of the most primitive description. At the commencement of the rains, about the first week in May, the Brahminical custom* is still followed of formally inaugurating the rice-planting season with sundry open air ceremonies. An inaugurator having been chosen by lot from amongst several nobles of rank, a bullock of the best breed is selected and decked with sweet-smelling flowers, and the whole procession moves towards the plain of the paddy fields. The chosen chief then has placed before him three strips of cloth of different breadths, which he takes up and unfolds one by one. If the cloth thus taken is not more than four cubits broad, rains will come early and water will be plentiful; if not more than five cubits broad the water supply will be up to the average; and if six cubits broad, water will be scarce. This done, the master of ceremonies proceeds to stand by the plough with bullocks yoked, and with it makes a circuit three times in succession round a plot of Government paddy-land, which an elder present then sows with rice. After which, Brahmin priests place on a table near by three kinds of grain, with fruits of all kinds, and the bullock having been taken from the plough is allowed to eat of them. Of whichever kind of fruit or grain the animal eats, that kind will be most plentiful during the coming year. This concludes the ceremony, and from this date the agriculturists are permitted to plough and cultivate their rice-plots.

Of paddy-land under rice tillage there are two kinds, one called "Khu Kho," extending from Nontaburi on the Northern outskirts of Bangkok to Paknam on the south, and the other "Pak Loi," from Nontaburi, northward to Intaburi, a short distance south of Chaiyat. The rice obtained from the former is the so-called nasoon, or garden rice, sown in nurseries and planted out by hand. The annual tax on each rai, 20 fathoms square, of this land is 24 atts 9d. Each rai is again subdivided into four parts called "ngan," of 100 square fathoms each, on which the tax is 8 atts (3d.) on each "ngan" below three. The rice reaped from the "Pak Loi" land is named "na uuiang," or field rice, which is sown broad-cast and left to grow as sown. The tax is 16 atts (6d.) on each rai, and 8 atts (3d.) on each "ngan" above two. It is impossible to ascertain the area of land in Siam under rice cultivation, owing to the unsystematic manner in which the land taxes are collected.

The Siamese agriculturist has no idea of the rotation of the crops. If he has not sufficient capital of his own, he obtains at high interest an advance large enough to cover the expenses of ploughing, ploughing, and harrowing during the six months in which he is compelled to work. During the remaining six months the generosity of husbandmen in Siam dissipate their earnings in the local gambling houses,

The ownership of land is mostly hereditary, remaining in the hands of one family for many generations. European traders, as a rule, refrain from making advances to the agriculturists, on account of the insecurity of the investment. Rice is sown year after year on the same ground. Irrigation is almost totally disregarded. If the rice-land is adjacent to one of the numerous creeks, either natural or artificial, intersecting the country, the owners may consider themselves fortunate; but there is no co-operation amongst those whose rice-plots are at a distance from the water-courses. The Siamese peasant is slow to take up new methods, and even if European machinery were to be introduced, he would look on the experiments with distrust. He is equally careless about his grass or pasture land, taking no trouble to sow good seed or hedge round a grazing ground of his own; but allows his cattle to roam at will over the thickly populated country districts. The pasturage is the common property of the village. The cattle graze there until the rice-crop has been gathered, when they are turned out to browse on the stubble. In addition to rice, teel-seed, hemp, tobacco, sugarcane, cotton fruit, and vegetables are also cultivated. Hemp grows extensively in the districts of Petchaburi to the south-west, and is tended by the Laos and Siamese peasants of that province. A tax is levied equal to one-fifth of the value. The drug is smoked largely by the paddy cultivators. Tobacco is grown in 42 districts of Siam, and is one of the most important local industries.

The Siam tobacco plant is sown in September by the Chinese cultivator, and the leaves are gathered in December. After gathering the leaf is left to ferment in some dark place during three or four days, and subsequently brought to a certain degree of ripeness by exposure to the night dew. In Deli, the difficulties encountered are the lack of proper coolie labour and attacks on the plants and leaves by earth-grubs. In Siam, if planting were to be undertaken by Europeans, the same would be found. The Siamese coolie is lazy and untrustworthy, and Chinese could only be engaged by paying them in proportion to the results of their work, and by cultivating good relations with the local governors. The quality of Siam tobacco differs according to the districts in which it grows. In many cases the salt absorbed interferes with the burning properties of the leaf. The best leaf comes from the Petchabun, from Kanburi and from Nakhonsawan.

The coffee shrub is as yet but little cultivated in Siam. The slopes of the hills at Chantabun and Korat are spoken of as highly favourable to the growth of the berry; and in view of the contemplated railway to the latter place, plantors might consider, Mr. Beckett thinks, the venture worth at least a trial. The low-lying land in and around Bangkok is well adapted for the culture of fruit, of which the most common varieties are:—Mango, durian, rambutan, pomegranate, orange, jack fruit, mangosteen, bananas, custard and pine-apples, and many others. Plantations of fruit-bearing trees are subject to annual taxation, assessed once in each reign on a scale based on the circumference and height of the trees. The assessment is made regardless of new trees that may have been planted, or old trees that may have died off during the interval. The consumption of fruit is almost entirely local. The produce being hawked about on river and land, chiefly by women.

If, continues Mr. Beckett, agriculture in Siam is one of the most primitive character, the condition of local industries is still less developed, being confined to weaving of silk and cotton native cloths, the manufacture of native paper from bark of the "khai" tree, the making and colouring of tiles for use on the numerous temple roofs, and the manufacture of earthen jars as receptacles for water, working in gold and silver, mat-weaving, and a few others. The carpentering and boat-building trades are carried on by some Siamese, but Chinese are superior at these handicrafts. The latter also monopolise the brick-laying, tinkering, dyeing, and similar industries. Most Siamese prefer to attach themselves to the person of

* Brahmins and Brahminical customs in the Buddhist country of Siam just as we have the mainly Hindu Petchera in Ceylon.—ED. T. A.

some influential noble, and throughout Siam, and in Bangkok especially, there exists a system, resembling that of feudal vassalage, by which each person, according to birth, position, or descent, forms one of a class owing dependence to a particular master or over-lord, under whose protection he is, and to whom he devotes his services. Most minute registers are kept of all such persons. Under certain circumstances the character of a guild is nearly approached when certain trades and handicrafts remain hereditary in a particular class or department, such as, for instance, in that of clerks and painters, potters, lacquerers, goldsmiths, incrustators, boatmakers, engravers, jewellers. Such persons receive salaries ranging from 6 ticals (12s.) to 120 ticals (12l.), including food, according to rank or individual ability.

When not serving their over-lord they can employ substitutes on payment to the latter of a sum of 6d per diem. This system of vassalage, now so thoroughly engrained in the national life, has many drawbacks, but it would be difficult to say if its abolition would be productive of much good; or stimulate the Siamese artisan to the development of local industries. His wants are small, a wage of 10 ticals (1l.) a month being ample to provide him with food, dress, and lodging; and if he be a man of means and ambitious of following the custom, which is now being more and more adopted, of wearing European articles of dress, if he can purchase his requirements at Bangkok and other important towns on the main river routes. Every year Siam is becoming more dependent on the manufactures of Europe and China, and there is a fear that the few existing local industries will soon be outstripped by foreign competition.—*Straits Independent*.

PATENT TEA CHESTS.

The following paragraph has reached us from Messrs. Andrew Polson & Co., of Glasgow:—

We hear from time to time of tea chests being invented to supersede the old wooden ones; and we have just seen one which promises to do away with tea lead, nails, hoops, &c.

The patentees think the cost will be only a little more than the cost of wooden chests. Apart from being able to dispense with the use of lead, nails, hoops, &c. a large saving will be effected in the factory. One cooly will be able to pack, (screw up and make all ready for shipment) a large number of chests in a day. We cannot say anything more in the meantime as the patentees hope to have the chest in the market with full particulars shortly. A gentleman with large experience saw the chest today and says he thinks it is sure to be a success. Granted that the chest is a success, the only question is that of cost; freight to Colombo can, we have no doubt, be arranged with shipping companies. Perhaps in this way:—We will take out 10,000 empty chests if you guarantee to send 10,000 full ones back by our ships, same as the railway carries books, &c. freights, Concessions as great as this are done daily by shipping companies."

THE REGULATION OF SUPPLIES.

To the Editor of the Home and Colonial Mail.

SIR,—In your last issue you publish a very sensible letter on "The Regulation of Supplies" of tea from a correspondent signing himself "Vis Uita Fortior."

I believe, however, that when he writes "Remember that when it was seen ten months ago that the Indian crop was short and the price rising, word was passed round Ceylon to make all the tea they could—the object being, of course, to hasten the displacement of Indian"—he is doing either more or less than justice to the foresight of the tea planters of Ceylon.

It was well recognised in Ceylon that the great increase in the shipments of tea in the first half of this year was due to the unusual continuance of wet forcing weather, which, while largely increasing

crops, added also greatly to the difficulty of proper preparation of the leaf, and so caused much of the tea shipped to be of inferior quality.

It is possible, also, that Ceylon planters had been to some extent predisposed to heavy plucking by the state of the London markets during 1890, when the ranges of prices for tea, whether of high or low quality, was comparatively small.

Till I saw the letter above referred to, I never heard it even suggested that Ceylon men had been moved in this matter by a wish to combine for the purpose of damaging Indian tea in the market.

On the contrary, the principle that has hitherto guided them in any combined action has most surely been that "Vis Uita Fortior" still holds good as the rule of the two great tea producing interests of the Empire.—I am, Sir, yours, &c., WM. MARTIN LEAKE,

Secretary Ceylon Association in London,
4, Mincing Lane, Dec. 14.

CEYLON TEA.

(From the *Grocer*.)

In our last issue was published the usual monthly statement of the movements of tea at the Port of London, which shows the same marvellous expansion in the supply of and demand for Ceylon tea that has characterised the trade in this article from its very commencement, about ten years ago. During the first seven months of the present year the landings, in round numbers, have been nearly 55,000,000 lb., against about 37,120,000 lb. in 1890, and 28,444,000 lb. in 1889. The deliveries in the same period, it is an extraordinary fact to observe, have kept pace fairly well with this rapid increase in the imports, and have amounted to 49,203,600 lb., in comparison with 34,880,000 lb. last year, and 23,277,000 lb. in 1889; and the business still goes on expanding as fast as the crops grow larger every season. Another remarkable circumstance, is, that while the receipts of Ceylon tea here have been augmented by close upon 18,000,000 lb., those of Indian have not been rendered heavier by more than 8,693,200 lb., or barely half so much, and instead of a very substantial gain of 14,323,000 lb. in the clearances, as shown by the Ceylon description of tea, Indian sorts actually exhibit a deficiency of 1,979,500 lb. for the past eleven months. To satisfy these increasing requirements of Ceylon tea, it is reasonable to infer that there must be a constantly advancing rate of production, and it is therefore highly satisfactory to note that the entire crop, as gauged by the estimated shipments to the United Kingdom for 1891, will in the aggregate reach 64,000,000 lb., or 20,000,000 lb. more than in the previous season.

Having thus spoken of the quantity, we will now proceed to offer a few remarks on the quality of Ceylon tea imported into this country; and first, it must be understood that, without creating the least prejudice against either the growers or distributors, exceptionally large crops of any kind of produce—tea or anything else—are not always identified with superiority of condition or out-turn. Consequently it is no libel on the general character of the article to say that among the importations of Ceylon tea this year have been numerous samples of complete rubbish, which would not have been tolerated or received by the trade as tea in the smallest sense if they had been offered as invoices or breaks of Indian or China, and it is the magical name of Ceylon alone that has enabled importers to dispose of the said tea when other—and, in the opinion of some persons, more excellent—kinds have been long on the market seeking buyers in vain. Without at all diminishing the popularity of Ceylon tea, we may further state that, so common has been a deal of the supplies put forward of late that pekoes have been selling down to 6d per lb. and under, pekoe soucheongs as low as 5d broken pekoe at 7d and even less, and orange pekoe at only 7d besides broken sorts at the severely reduced figure of 4d per lb. At such cheap and popular prices surely there is a most powerful stimulus to an unstinted consumption, and a ready means for securing profitable returns on the capital invested by the wholesale dealers and others.

Further, it may be stated that, excepting for fancy trifling lots of gold and silver-tipped teas, prices of which are artificial, it has been quite a rarity and a wonder to see a line of Ceylon tea knocked down in public sale above 2s as the highest range of value for best qualities has mostly been from 1s 6d to 1s 10d per lb and even at these rates the parcels of teas realised at one time and another have been comparatively few. A principal cause of the larger proportion of inferior grades in this season's crop has been the continuous rains in Ceylon during the gathering and manufacture of the teas, which, besides adding to the difficulties of drying and withering the tea, have partly spoiled the quality of the same, and left in many gardens and estates little else but rubbish to be exported to England. From the latest information we can glean, however, it is expected that these adverse conditions of preparing tea for the London market will soon be overcome, and if so a decided improvement in the assortment of Ceylon teas will probably follow, and then this branch of the trade will be in a stronger position than ever to compete with the low-priced growths of India and China. In the meantime stocks on this side are excessive, embracing 14,966,000 lb. as contrasted with 8,505,000 lb. in December last, and until the extensive surplus here apparent is worked down, quotations generally may be reckoned to rule as much as ever in favour of both retailers and consumers.—*H. and C. Mail*, Dec. 18th.

THE REGULATION OF INDIAN TEA SALES.

TO THE EDITOR OF THE "HOME AND COLONIAL MAIL"

Sir,—In the letters addressed to you by Mr. Shillington and "Observer," a subject has been broached which seems to merit more thorough discussion than it has yet received. Prefacing what I have to say with the remark that my interests are bound up with those of producers as closely as any man's can be, and that I do not write with a controversial object, I will briefly analyse the substance of their last letters.

In them, the following propositions are assumed:—

- 1.—That supplies of Indian tea are being unduly forced on the market,
- 2.—That the value of tea would be raised by reducing the supply now, and reserving some of it for sale during the summer months.
- 3.—That it is possible for sellers to combine here to regulate supply.
- 4.—That the brokers are answerable for this not being done.

For propositions 1 and 2 Mr. Shillington is responsible. His opinions always deserve consideration; but in this instance they do not accord with the judgment of the greater number of those engaged in the trade, whether as importers or buyers. It is a matter of common knowledge that each succeeding year finds buyers less willing to take tea of the old crop after April, or May at the latest. The less to those who have held for the summer demand—whether producers, dealers, or speculators—is as well known as the reason for it is obvious—viz., the inflow of heavy supplies of fresh tea from Ceylon after March. The bearing of this is so fully appreciated that in future every producer of Indian may require his crop closed by April, just as every grower who sells in Calcutta cloths to wind up his sales before March, if he can.

This being so, the realisation of the great bulk of the imports must take place between September and April. By the use of simple arithmetic, anyone who knows what the total supply will be can find that to dispose of the crop it is needful to sell some 40,000 packages per week from Sept. 1 onwards, and a reference to the circular file will show that the average since that date has been not more than 38,000 packages per week.

But apart from the arithmetic problem, is it really the case that prices can be raised, except to the most temporary and trifling extent, by the process of feeding the market? Surely the value of a large article of commerce like tea depends upon the relation of

total supply to the total requirement. Those who think otherwise forget that in these days the buyers have the same opportunities of obtaining information as the sellers have with respect to supplies. They are able to calculate for themselves the probability of excess or deficiency; they know how many chests arrive each day, and how much of it is held and how much sold. Nothing destroys their confidence in buying so much as the knowledge that supplies are being kept back, hanging like a cloud over the market ready to come down, as the rain does, it may be when least wanted.

Your correspondent "Observer," having assumed the soundness of Shillington's propositions, adds to them two of his own. Let me briefly examine them. He assumes that it is possible for importers to act in concert. Those who have earnestly tried to effect this know the exceeding difficulty. Only a few weeks ago the brokers met in solemn conclave, and passed a resolution declaring that it was desirable that only 35,000 chests per week should be put on the market. What followed? Within a fortnight the maximum was largely exceeded. Why? Because no machinery can be devised to carry out what is aimed at. Why not? Because every importer wishes *someone else* to hold, in order that he may sell to better advantage; but as for holding off himself, well he is not quite sure that this would be wise!—and so the brokers' deliberations ended in a farce.

Now let us go a little deeper beneath the surface. Run through the names of the great agency houses which manage the affairs of the industry in London, add to them the experienced managers and directors of the large companies whose headquarters are here, and you will find among them men of the highest business capacity and foresight—men who know how to manage their own affairs, and prefer to manage them in their own way, declining to limit their freedom of action by entering into combinations. Is it for the broker to go to such men and say, "We advise you not to sell, Messrs. A., B., and C. are offering large quantities this week and next, hold your teas for awhile?" Why, Sir, any broker who did that would speedily find himself among the ranks of the unemployed, and deservedly so. A broker's business is to obey orders, and carry out his employer's instructions as honestly and carefully as he can. Remember too, that one-third of the supplies are imported by speculators who buy in Calcutta; in no possible combination of products could they be included.

A friend at my elbow suggests to me that I should say something about "Observer's" warning to the brokers that if they do not succeed in raising the price of tea the importers may dispense with their services and "broke" for themselves; but I am loth to refer to such an uncalled-for threat, except to place it in the same category as another rumour which is current to the effect that certain enterprising firms are only seeking an excuse to add the functions of grower's agent to that of broker, and all for 1 per cent.! May each prove the antidote to the other! *Ne sutor ultra crepidam*, said Apelles to the shoemaker who daubed his wall with paint, and thought he was an artist. Fortunately there are still old-fashioned folks who respect the recognised boundaries of their several callings; but if the struggle for existence is to be carried to such a point as "Observer" hints at, well, I suppose the fittest will survive.

But can we do nothing to help each other out of the ditch into which we have fallen together? "Observer's" most valuable letter in your issue of the 13th, points to one way: let me indicate another. London is too large a place for combinations, but what is not feasible here may be possible elsewhere. Go to the source and fountainhead, India; and here a dozen more or less conflicting home interests are concentrated in a single focus, and if concerted action be possible at all, unite not to manipulate supplies, but to *shorten the output*. Let us have the courage to face the facts. We are suffering from over-production, and if growers would agree to make 10 per cent. less tea in India and in Ceylon, we should soon see a very different state of things. Too many were misled by the inflated

market in the spring and the real lesson which the present distress should teach us is that it is hopeless to expect a paying price if we over-supply the market with an indifferent article. No one who has been content with moderate crops of really good tea had cause to complain of results.—I am, Sir, yours, &c.,

VIS UNITA FORTIOR.

BULKED TEA,

(From the Grocer.)

Our readers are aware of the immense importations of teas from India and Ceylon, and of these a large proportion either is or ought to be bulked in London; for although the bulking operation when properly performed at the garden where the tea is grown is desirable, it has been found by experience that in many cases the machinery and other means for bulking abroad are imperfect. On arrival in England the chests have been found irregular in quality, thus rendering the mixing here absolutely necessary. This is a matter of regret because the exposure of the tea in a damp climate like ours must depreciate the value, particularly to grocers, who have to hold stocks either at their shops or in the large bonded warehouses. There is, however, another evil to which attention should be directed: it arises from the impatience manifested by importers to place their teas upon the market before they are ready for sale. Thus it sometimes happens that a parcel of tea is sent up from the docks to an up-town bonded warehouse, and, when bulked, samples are sent out and the tea sold; but shortly afterwards some packages—usually known by the name of “missing packages”—are found, which belong to the same consignment, and are forwarded to London, being then mixed with some of the chests remaining in bond.

One condition regulation public sale provides that missing packages up to a small percentage of the parcel, if equal in quality to the bulk, must be taken by a buyer; but the fact of the tea being bulked is an evidence of variation in quality, and unless the whole of the tea is properly mixed we failed to see how it could have been fairly represented by the sample upon which it was sold. In fact, this condition respecting missing packages can only apply to teas bulked abroad, or those from gardens whose the quality is so regular that the bulking process is rendered unnecessary. This subject is of special importance to grocers who regulate their blends upon the samples of the first chests of a parcel they receive, and any variation in the quality of the missing packages may make a material difference in the blend and do them great injury with their customers, who are quick in detecting any variation in the liquor of a tea. Although in some cases the quality may be really better than that of the parcel, if there is a difference, and it is detected by the consumer, unfavourable conclusions are too frequently drawn which can only prejudice the trade. All missing packages of bulked tea should be sold separately, not palmed off on the buyer of the parcel; and considering the number of complaints which have been made of the variation in quality, this principle should be adopted. We understand the London Wholesale Teadollers' Association have this matter under consideration, and we hope they will lose no time in bringing about a substantial reform in the direction indicated. It would save wholesale dealers the annoyance and vexation of numerous complaints, and would be an act of justice to grocers generally.—H. and C. Mail.

COCONUT AND CINNAMON CULTURE IN CEYLON IN 1891.

COCONUTS.

The year that has just closed has been an exceptionally favorable one, as regards rainfall, for coconut cultivation, the more especially in the coconut-growing districts in the southern and western portions of the island where the rainfall has been abnormally high. As can be readily understood, water is an important factor in the cultivation of a

product whose fruits are always carrying several gallons of liquid and whose leaves, being constantly moved by every gust of wind, favor rapid evaporation from their surface. But as in most things, there can be too much even of a good thing like water, and reports from the inland districts say, that with a lesser rainfall and more sun the prospects of crop for this year would have been better. Not that they are by any means such as to cause grumbling, but they are not as good as they might have been. This can be readily understood, for the soils in the inland districts are mainly clayey, and the persistent rainfall has so sodden them that the short intervals of sunshine have not more than warmed the surface, and thus the circulation of air through the soil, so necessary for the vigorous growth of vegetation, has been possible only to a limited depth.

It may be remembered that the year 1890 was distinguished for a drought extending from June to October, and which was felt severely along the coast from Jacla, 12 miles from the capital, to the North of the island and on to Batticaloa on the East coast. Its severity was felt most in the districts north of Negombo, increasing as we go further north, till in Jaffna not only coconut trees but even the hardier palmyra palms succumbed to it, and many plantations at Batticaloa were said to have lost a good number of their well-established coconut trees. Its effects were as a matter of course felt during 1891 in diminished crops and in nuts of abnormally small size; but the severe “wintering” the palms received have helped them to realize to the full the beneficial effects of the wet year we have just passed through, in bright prospects of crop during 1892.

During the first six months of 1891 the prices of nuts were such as to cheer the hearts of coconut planters. There was great activity in the trade and the enquiry for nuts was brisk. In July-August the demand ceased suddenly and the drop of prices was fully Rs 5 per thousand. As can be imagined, this caused much loss both to buyers and sellers and the market was for a time greatly disturbed. Prices have not risen since, and were Rs 4 or 5 less per thousand at the end of 1891 than they were during the same period of the year previous.

Though the desiccating of coconuts is not an industry that started into life during the past year, yet it deserves notice owing to the large number of nuts it consumes. The oldest establishment is at Colombo, where Messrs. Vavasour & Co. are said to have set up over half-a-dozen of Brown's patent desiccators and whose the daily consumption of nuts must be about 20 or 25 thousand. The mills at Veyangoda are constantly expanding, and the daily consumption of nuts there is said to average between 10 and 15 thousand. The enterprising Akbar Brothers started a desiccating mill at Negombo, but ceased working it after a very short while, for reasons which must be best known to themselves. Sinhalese gentlemen of equal energy and enterprise, the Pieris Brothers of Grandpass, have established a factory for the same purpose at Kolani, so coconut planters have not, like tea planters, to fear over-production just yet. A letter appeared in our columns a few months ago from a merchant in London expressing grave fears that the desiccating of nuts is already being overdone and that a promising industry was likely to be ruined. It is generally believed that the letter had emanated from an interested party who was anxious to reap as much of the profits of this industry as he could himself. The rumours outside are that desiccated coconut sells at Rs 1 per lb. in Europe. A thousand coconuts are reported to yield about 350 lb. of desiccated stuff, and a thousand nuts sell for between Rs 30 and Rs 35, so that the difference between Rs 35 and Rs 350, after deducting cost of production, packing, transport, interest on capital and other et ceteras, represents profit. From these figures it will be seen that if they are reliable it will take some time to render the industry unremunerative through over-production. But it is said the demand is limited. This is a serious drawback with a product that will not keep longer than 3 months. In spite of it being packed in air-tight cases precisely like tea, the stuff is said to become rancid after that

period of time; but it need not go to waste even then, for if it be not sweetened it can be used for expressing oil.

We have heard very little of cocconut leaf disease during the past year; but we are assured that this is not due to its absence, but to a desire by estate proprietors to keep the matter to themselves. With reports of a disease with a fatal termination in Jamaica, we think the wiser plan will be for proprietors to boldly face it and with the assistance and advice of the School of Agriculture devise means to overcome it.

CINNAMON.

The prayerful wish of all cinnamon planters must be that they will not pass through such another year, as regards prices, as 1891. Though Ceylon has the monopoly of the cinnamon market,* yet she has not been able to devise means to control it. Combination amongst cinnamon growers is impossible. One of the first acts of the now defunct Agricultural Association was to resolve that the antiquated system of quarterly sales of the spice in the Lane be abandoned and monthly sales substituted. There was nothing revolutionary in this change, for all other products are sold once or twice a week, and every other spice but cinnamon is sold weekly. The change met with a most determined opposition by the buyers, whose chief complaint most strangely was that the change would affect prices prejudicially! We believe that this is the first instance on record in which buyers expressed a disinclination to buy in a cheap market. The fact is that the only opponents of the monthly sales were the middlemen, who are the principal buyers and who lay by stocks for the intervals between the quarterly sales. They feared that their occupation would be gone if it became possible for the consumer to satisfy his requirements at frequent sales. Those who initiated the change on this side were looked upon by the older cinnamon planters as youthful enthusiasts with more enthusiasm than discretion, and their lead was followed under protest. The opportunity to revert to the old system was eagerly seized when at one sale buyers refused to bid. The combination was thus broken up and the better prices which the "old hands" expected would be coincident with the reversion to the quarterly sales have not so far been realized. Indeed prices have been steadily receding. An attempt to arrest this was made by Mr. Jardine summoning a meeting of cinnamon planters to discuss the possibility of abandoning the scraping of cinnamon chips and thus lessening production. An undertaking "ou honor" was signed by growers representing about two-thirds of the acreage under cinnamon not to scrape chips. How much this undertaking was respected can be inferred from the fact that the export of chips was not diminished during the twelve months that the undertaking was supposed to be observed! During the past year the scraping of chips was resumed.

At the May quarterly sales only about one-third of the cinnamon offered changed hands. There was no enquiry whatever for the finer qualities. Agents and brokers in England suggested as a remedy that only cinnamon of inferior make, for which only there was enquiry, should be shipped but under another mark, so that the old well-established brands should not be imperilled. Very few estates we believe followed that advice. The next quarterly sales in August showed no better results, the finer qualities being as before neglected.

As the year was closing came the results of the last quarterly sales in November. They are such as to cause the gravest anxiety. There has been a further drop in the prices of the finer qualities, and no cinnamon but that of Goluapokuna, which seems to be in special demand in Spain, the chief consuming country, fetched higher than 1s per lb for its best quality. This is very nearly one-third of the prices ruling 15 to 20 years ago. To add to low prices, cost of manufacture has increased and the yield per acre has decreased by about 20 per cent owing to tender sticks only now being cut for the finer quality of cinnamon

now manufactured. Cinnamon planters fervently hope that the bottom, as regards prices, has now been touched and that the new year on which we have entered will reveal to them a turning in that long lane of low prices through which they have been painfully traversing during a good many years. That their hopes may be realized is our hearty wish, for the trade in cinnamon is one of historic interest and is supposed to go back to the time of Solomon and even to the period of the Patriarchs.

CEYLON TEA FUND.

Minutes of proceedings of a meeting of the Standing Committee of the Ceylon "Tea Fund" held at Kandy on Monday, the 4th day of January 1892, at three o'clock in the afternoon.

Present:—Messrs. Giles F. Walker (Chairman, Planters' Association of Ceylon), A. T. Karlake (Kandy), W. D. Gibbon (Kandy), T. O. Owen (Kandy), A. G. K. Borron (Kandy), A. W. Stopford Sookville (Chairman, Maskeliya Association), James H. Barber (Kandy), Dr. V. Duko (Kandy), Mr. J. Anderson (Kandy) and Matula West, Hon. L. H. Kelly, M.R.C. (Kandy), Mr. A. Philip, Secretary to the Planters' Association of Ceylon (Kandy).

The notice calling the meeting was read.

The minutes of proceedings of a meeting of the Standing Committee held at Kandy, on Friday, the 11th day of December 1891, were read and were confirmed.

CEYLON TEA AT THE WORLD'S EXPOSITION AT CHICAGO IN 1893.—Read letters from Mr. J. J. Grinlinton (1) conveying his thanks for the mark of confidence placed in him by the resolution passed requesting him to act as a Commissioner to represent the planting interests at the Chicago Exhibition, and intimating that should His Excellency the Governor appoint him Commissioner it will be his duty as well as pleasure to give the planting interests his unremitting attention; (2) transmitting a memorandum of information given to Mr. Grinlinton by Mr. Erskine Phelps, late Chairman of the State and National Exhibition Chicago.

Read letter from Mr. Chas. Stouter, Colombo. Resolved:—"That the letter be acknowledged."

The Chairman introduced Mr. Grinlinton to the Standing Committee of the "Tea Fund," and Mr. Grinlinton explained his views and urged the necessity for prompt action.

CEYLON TEA IN GERMANY.—Considered the question of a subsidy of Ceylon tea to Mr. Schrader. Resolved:—"That the Standing Committee of the Ceylon Tea Fund do grant to Mr. Schrader 5,000 lb. of Ceylon tea in two instalments for free distribution in Germany, the Committee understanding that Mr. Schrader is prepared to purchase an equal quantity of Ceylon tea on his own account."

CEYLON TEA IN RUSSIA: MR. ROGIVUE'S REPORT AND ACCOUNTS.—Read letter from Mr. Rogivue, Moscow, transmitting his Report, together with accounts, in reference to his mission to Russia to make known and push the sale of Ceylon Tea in that Empire. Resolved:—"That in acknowledging Mr. Rogivue's letter he be informed that the Standing Committee of the Tea Fund trusts to receive further accounts showing an increasing sale of Ceylon Tea in Russia during the present year, when the Committee will be prepared to consider what further assistance they may be in a position to give Mr. Rogivue at the next Fair at Nijni Novgorod."

CEYLON TEA IN SWITZERLAND AND AUSTRIA.—Read letter from Mr. Charles Oswald, Winterthur, on the subject of introducing Ceylon Tea into Switzerland, and also making further proposals in regard to Austria as indicated by Mr. J. Ferguson's letter to the *Ceylon Observer*. Resolved (1):—"That a grant of 500 lb. of Ceylon Tea delivered free at Trieste duty paid be made to Mr. O. Oswald for gratis distribution in Vienna by Mr. Weiner; (II) that Messrs. Whittall & Co. be asked to purchase the Tea."

CEYLON TEA IN VIENNA, PRAGUE, KARLSBAD, &c.—Considered Mr. John Ferguson's suggestions in 4

* Only for the finer sorts: in coarse kinds China is a formidable competitor.—Ed., T. A.

series of letters to the *Ceylon Observer*. Resolved.—“That the Director of the Royal Imperial Austrian Oriental Museum, Vienna, be asked to inform the Committee what samples of Ceylon teas he would wish to receive for Exhibition giving details as to the most desirable way of packing the samples with any further information that may occur to him.” Resolved.—“That a copy of these resolutions be forwarded to Mr. Ferguson.”

CEYLON TEAS IN PARIS.—Read letters from the Secretary, the Ceylon Association in London in regard to the proposed joint operations in Paris with the Palais Indien Tea House, Limited.

ANALYSES OF SAMPLES OF CEYLON TEAS.—Read letter from Mr. H. Atkinson. Resolved:—“That Mr. Atkinson be thanked for his letter, and informed that the consideration of the question he refers to will not be lost sight of.”

CEYLON TEA AT THE KIMBERLEY EXHIBITION 1892.—Read letter from the Secretary, the Ceylon Chamber of Commerce, forwarding copy of a letter received from Mr. Litchfield Green, Secretary of the Kimberley Exhibition of 1892, and asking if the Association had received a similar communication and also enquiring if the Association intends taking any steps in the matter. Resolved:—“That the Standing Committee of the Tea Fund do not recommend any part being taken by the Planters' Association at the Kimberley Exhibition of 1892.”

Read letter from Messrs. J. M. Robertson & Co. Resolved:—“That the letter be acknowledged and that they be informed that the point raised in their letter will receive early consideration from the Standing Committee of the Tea Fund.”

The Standing Committee of the Tea Fund then adjourned.

A. PHILIP,

Secretary to the Planters' Association of Ceylon.

FOSSILS FROM DOLOMITE AT PUTTALAM.

Mr. H. P. C. Armitage writes from Puttalam:—

“I wrote you some time ago about the find of dolomite north of Puttalam. I am now sending you, by a friend, about ten fossils found in it. They are mostly shells, and that they are fossils is indisputable. As there has been a great deal of controversy as regards the finding of fossils in Ceylon, I have been at some trouble to solve the doubt, and am glad to be able to send you what I believe to be the first fossils found in Ceylon. I shall be glad if you will after inspection send them on to the Museum as a loan from me.

“This dolomite runs all along the coast and is found cropping up some miles inland. I hear that there is a formation of coral up north of Karaitivu also.

“At Kalpitiya and down most of the Akkarai Pattu, a layer of sand and lime, about one or two feet thick, exists. It has formed a hard conglomerate or breccia, being all cemented together, and is used for the Akkarai Patta road. After going below this one again comes on the regular sandy soil. Coconuts would do much better in many parts if this layer of rock was non-existent, I expect, as it is only 2 to 6 feet from the surface. I attribute to this rock, however, the good water generally obtained in those parts, as all the water is filtered through this rock, which is porous and soft on first cutting it, but it becomes hard after exposure to the sun.

“I hope to write you soon a long paper on the geology of this district, which is the most interesting I have yet seen in Ceylon.”

This find of true fossils in one of our primitive rocks is very interesting, and we shall be glad to receive the detailed information promised. Tennent wrote positively, “the rocks of Ceylon are entirely destitute of organic remains.” He added a note as follows:—

At Outchavelly, north of Trincomalee, there exists a bed of calcareous clay, in which shells and crustaceans

are found in a semi-fossilised state; but they are all of recent species, principally *Macrophthalmus* and *Scylla*. The breccia at Jaffna contains recent shells, as does also the arenaceous strata on the western coast of Mannar and in the neighbourhood of Galle. The existence of the fossilised crustaceans in the north of Ceylon was known to the early Arabian navigators. Aboazeyd describes them as, “Un animal de mer qui ressembloit à l'écrevisse; quand cet animal sort de la mer, il se convertit en pierre.” See Renaud, *Voyages faits par les Arabes*, vol. i. p. 21. The Arabs then, and the Chinese at the present day, use these petrifications when powdered as a specific for diseases of the eye.

Mr. George Armitage, however, believes that he has actually found fossils in our gneiss rock. If that belief is well founded, our correspondent cannot claim priority, although the largeness of his find makes the discovery important. Mr. H. P. C. Armitage, it will be soon, is confident that the limestone is really dolomite and the organic remains real fossils.

THE INCREASE in the use of cocoa in the United States during the past few years has been remarkable. During the year ending June 30, 1891, the imports of cocoa crude and leaves and shells thereof, were 21,539,840 pounds, of which 1,939,308 were re-exported, leaving net imports of 19,600,532 pounds. In 1880 the entries for immediate consumption and warehouse withdrawals for consumption were 7,411,045 pounds, and in 1876, only 4,655,793 pounds or less than 24 per cent. of the quantity at present used. This is strong testimony in favour of the popularity of cocoa. The figures given do not include prepared cocoa or chocolate, of which 1,615,401 pounds were imported in 1890 paying a duty of two cents per pound.—*Am. Grocer*.

PERAK TEA.—The *Singapore Free Press* of 18th December says:—Dieraeli was once recommended to try Australian Wines for the gout. It was in the early days of the corn-stalk vintages, so that no reflection is cast on the productions of the present day. He wrote that he had tried it—and preferred the gout. That is exactly how we did not feel after trying Perak Tea. The first morning the “boy” made it dark brown and bitter: we learned incidentally that he had been a couple of hours too previous in his forecast of the time the matutinal tea would be wanted. The next morning we had less tea put in, and tried it five minutes after brewing. The favour was splendid in our opinion better than that of Indian or Ceylon tea. People who want to try Perak tea fairly should see that it is properly made; then if they don't admit that it is good we shall feel inclined to say they like “black cap” best.

JUTE MILLS IN FRENCH TERRITORY.—Messrs. Gillanders, Arbutnot & Co., of Calcutta, have applied for and obtained sanction from the Pondicherry Administration for erecting and working, by steam power, a spinning and weaving mill, on a block of land belonging to them situated at Gonalpara, in the Chandernagore colony. The firm intends to manufacture jute into cloths and gunny bags for export and for local use; and is sanguine of being able to compete successfully with similar factories in Bengal. Messrs. Gillanders, Arbutnot & Co. are required, by the French Colonial authorities, to execute a bond assuring the salubrity of their establishment, and their willingness to conform to the rules and regulations of “public ways,” as ordained for the colony. This is the third jute mill, for which sanction has been asked, to be erected at Chandernagore; and the future prospects for the once gay little colony are encouraging.—*Indian Engineer*.

PRESERVATION OF COCONUT TREES.—Under this heading the following Order in Council has been issued by the Perak Government:—

Whereas the provisions contained in Government notification No. 99 of 25th September, 1888, have proved insufficient to prevent the destruction of coconut trees by beetles, the following is added to the abovementioned notification. 1. All owners and occupiers of land in the vicinity of coconut plantations are required to burn the dead stems of all palm leaves that may be on their land, as it is in these stems that the beetles generally breed. Further, they are forbidden to accumulate heaps of decaying vegetable matter, old attaps, and the refuse of sugarcane or Indian corn, and where these have accumulated they are to take immediate steps for their removal or destruction, preferably by fire. 2. Any person neglecting to comply with the provisions of Section 1 of this Order in Council shall be liable, on conviction, to a fine not exceeding \$10 for the first and not exceeding \$50 for a second or subsequent offence.

THE MADRAS SEASON REPORTS.—The distress in this Presidency is becoming more and more concentrated every week. Chingleput and North Arcot are now reported to be out of the area of anxiety, at least for the present, and Kurnool, Bellary, Anantapur and Cuddapah have taken their place. The season telegrams in last night's *Gazette* for the week ending the 12th inst. report heavy falls of rain in Tanjore and South Arcot, and good falls in Trichinopoly, Chingleput, eastern parts of North Arcot and southern portions of Nellore. And since these reports were sent in we learn that large amounts of rain have been registered all round Madras and down south, that many tanks in North Arcot, Chingleput and Nellore have now a full supply, while most of the rest have a fair supply. The rain, however, did not extend far inland, and drought is now being severely felt in many parts of the centrally situated districts. In Kurnool, Bellary and Anantapur the dry sowings up to November were 768,000 acres deficient. Cattle, too, are now suffering severely in Bellary and Anantapur. Prices have further risen during the week. Last Wednesday we showed how dangerously high they were, and we regret to observe that the scarcity rate for rice has now been reached in Vizagapatam, and for dry grains in Nellore, Kurnool and Salem. Ourlously enough, there continues to be a decrease in the numbers on relief works and in famine kitchens, but when relief operations have been thoroughly started in the Ceded districts we may expect large and sudden increases.—*M. Mail*, Dec. 16.

PUBLIC COMPANIES AND ESTATES IN BRITISH NORTH BORNEO.—To Mr. Henry Walker, Commissioner of Lands, we are indebted for an interesting return so entitled. Of the 28 companies the British North Borneo Company is beyond all compare the most important, with 2 millions sterling of capital, and 20 millions of acres of land,—that is to say 5 millions beyond the area of Ceylon! This Company will of course take up all possible enterprises. The rest are all tobacco companies, excepting one for gold mining, one for mining rights and planting, two for hotel and stores, two for planting, saw-mills, &c., and one various. There is no coffee, tea or cacao company; all save those mentioned are tobacco companies. Tobacco shows the same preponderance in the lists of private estates. Of 45 in the Myburgh district two are for timber, two various, leaving 41 for tobacco. In Darvel Bay 6 estates all grow tobacco. In Alcock Province there are 10 estates, all tobacco, except one Liberian coffee and one coffee and cacao. In Dewhurst Province 5 estates all grow tobacco, and so with 12 estates in Martin Province. This being so we are not surprised to find that the names of the managers are nearly all Dutch and German; there is little more than a score of English names to fully three score foreign. The tracts of land monopolized by companies and individuals are enormous, ranging after the 20 millions of the

great Company, from 50,000 acres downwards. The smallest acreage held by any public company is 3 577. One holding of 300 acres for Liberian coffee looks quite exceptional amongst the big figures. We trust British North Borneo will prosper, although at present the British element does not preponderate in the enterprise of the colony.

A FRENCH DUTY ON GROUNDNUTS.—An article which appeared in the *Madras Mail* on Saturday evening, the 5th instant, announcing that a telegram had been received from France during the day, to the effect that the Senate had voted a duty of 3 francs per 100 kilos (210 lb.) on groundnuts and gingelly seed imported into France, from any port except Pondicherry, caused an immense amount of excitement, for a time, and operators in the produce, of all classes of the traffic, rejoiced greatly, at the good tidings which were to spoil Madras and Cuddalore of their present groundnut and gingelly seed export trade, to the great advantage of the French port: it was settled, there and then, that the whole of the products, in question, exported from the Coromandel coast to France must, in future, be shipped from Karkikal or Pondicherry, while that from Bomhay would go to Mahé. But the news was too good to last; and a very few hours after the distribution of the *Mail*, the extraordinary news was authoritatively contradicted. It is true that a duty of 3 francs per 100 kilos has been voted by the Senate, but exemption applies only when the products are grown on French soil, and as there is no space in the Franco-Indian territories for producing groundnuts and gingelly seed for export, beyond perhaps 10,000 or at most 15,000 bags per year, the fair capital of French India is not likely, therefore, to be much benefited by the new import duty.—*Cor.*

EMIGRATION OF COOLIES FROM GANJAM TO THE INDIAN TEA DISTRICTS.—Recent articles which we have extracted from the *Pioneer* seems to show that the Assam planters are not so favourably situated in regard to cheap labour as Mr. Skrine's resolution assumed. Northern and Eastern India not being equal to their wants, they are now drawing labour from Ganjam in the Madras Presidency, where difficulties oppose themselves to recruiting which are thus stated in a Memorial to Lord Wenlock:—

We, the undersigned, agents for emigration of coolies to the Indian tea districts, beg respectfully to bring to your Lordship's notice the great inconvenience to which the coolies are put, and also the extra heavy expenses incurred by us in sending our coolies from Gopalpore to Chattrapore or Berhampore for registration. On the 21st of February last, we applied to E. C. Johnston, Esq., C. S., Protector of Labourers, to forward our appeal to your Lordship's Government to allow registration to be done at Gopalpore, the port of embarkation, but the concession was not granted. We take this opportunity of approaching your Lordship with this our appeal to grant us the concession asked for, namely that an office of registration may be extended to Gopalpore, as the coolies have to travel thirteen miles each way, in all a distance of 26 miles, for registration at Chattrapore, at which place registration is more expeditiously done than at Berhampore. We would also point out to your Excellency the disadvantage to emigrants, especially women and children, having to travel 26 miles, and their inability on such a journey to obtain properly cooked food previous to their undertaking a sea voyage to Calcutta. This state of matters is the more to be regretted, seeing that emigration is increasing every year, and that thousands of coolies are expected to emigrate from Ganjam during the current recruiting season. If deemed necessary, we are willing to pay cost of or fees for any extra establishment Government may think necessary for registration at Gopalpore. In conclusion, we fervently hope that your Excellency will take our humble petition into kind consideration. Gopalpore, Ganjam, Nov. 1891.

SINGULAR EFFECT OF CINCHONA.

The *Journal de Pharmacie* of May, 1819, gives the following account of the singular effect of cinchona bark:—A French merchant, called M. Delpech, who possessed a rich house at La Guayra, the port of Caraccas, had stored up in 1806 a very considerable quantity of cinchona newly collected. This bark filled several apartments upon the ground floor. There prevailed at that time in Caraccas a fever of a very malignant type. M. Delpech had occasion to receive several travellers, and to entertain them with the usual American hospitality. The apartments destined for visitors being filled, and the number of his guests increasing, he was under the necessity of putting several of them in the rooms occupied by the cinchona. Each of them contained from eight to ten thousand pounds of that bark. The heat was much greater in these rooms than anywhere else in the house, in consequence of the fermentation of the bark, which made them very disagreeable. However, several beds were put into them, one of which was occupied by a traveller ill of a malignant fever. After the first day, he found himself much better, though he had taken no medicine; but he was surrounded with an atmosphere of cinchona, which appeared very agreeable to him. In a few days he felt himself quite recovered, without any treatment whatever. This unexpected success led M. Delpech to make some other trials. Several persons, ill of fever, were placed successively in his cinchona dépôt, and they were all speedily cured, simply by the effluvia of the bark.

In the same place with the cinchona, he kept a hale of coffee, carefully selected for his own use; and likewise some large bottles of common French brandy. They remained for some months in the midst of the bark without being touched. At last, M. Delpech, when visiting his dépôt, observed one of the large bottles uncorked. He suspected at first the fidelity of a servant, and determined to examine the quality of the brandy. What was his astonishment to find it infinitely superior to what it had been. A slightly aromatic taste added to its strength, and rendered it more tonic and more agreeable. He uncorked the other bottles, which had undergone no alteration, but which, by being placed in the same circumstances, soon acquired all the good qualities of the first bottle. Curious to know if the coffee had likewise changed its properties, he opened the bale, and roasted a portion of it. Its smell and taste were no longer the same. It was more bitter, and left in the mouth a taste similar to that of the infusion of bark.

We are not prepared to believe this story in its entirety, though as regards the first part of it, it is more than likely that the sick man swallowed a great deal of dust and minute particles of the bark that were floating in the air. If only cinchona could be found of advantage for maturing liquor, a new impetus might be given to the trade. It is possibly needless for us to point out in this connection that cinchona bark is used largely in the manufacture of lager beer, taking the place of hops.—*Madras Times*, Dec: 31st.

QUEENSLAND.

[The following letter in the *Louisiana Planter* gives the best account we have seen of the position of the sugar industry in Queensland, conducted now with European labour.—*Ed. T. A.*]

Mackay, September 13th, 1891.

Editor Louisiana Planter: Few mishaps amongst the sugar machinery in this district, and none of a serious nature, have occurred to check the steady progress of crushing operations. The weather for the last few weeks has been uniformly fine, too much so, indeed, that a little moisture is now required to stimulate the growing crops, which are beginning to droop under the long spell of sunshine and light breezes. The crop now being harvested is somewhat disappointing, the late winter

having been an unsatisfactory one and the yield of the fields turning out to be more and more below the expected output as work progresses. The difference will, of course, be the merest drop in the bucket, but to us it is none the less annoying, even though it fails to appreciably affect the world's output.

European labor is plentiful enough this season, and wages are not very high. The ordinary mill hand gets from \$5 to \$20 a month and his keep, while the clarifier, boilers and other hands receive a rate from \$5 to \$10 higher. When wages in the mill alone add to the cost of making a ton of sugar by 2 per cent. (\$5), we consider more economy or a greater output is necessary.

The small mills are voted a failure, and in this district we have only two working this season, which will make much under 500 tons of sugar, or 1,120,000 pounds. Five mills will make between 500 or 1000 tons, and six 1000 tons and upward.

The factory at Homebush, the property of the Colonial Sugar Refining Company, making about 13,400,000 pounds this last season, has made considerable advance in procuring farmers to grow cane on the company's land, and now there are twenty-three men settled on 1000 acres of land, while small freeholders of neighboring lands are planting cane under five years' agreement. The mill pays from 13 shillings to 14 shillings a ton for all canes landed on tramway tracks, which are run into the field. The price seems a high one, and yet it is being paid to farmers everywhere. In fact, the European will not grow cane for less, as near the tropics as this, at any rate.

Our millers are all green with envy at the handsome bounties their Louisiana friends are getting for their sugar from the U. S. A. Government. According to the figures published here the amount received is over £9 a ton, a figure which to us would mean colossal fortunes in a very few years. The little Queensland industry has to fight the world, and is practically unprotected, as it makes more than is required for its own consumption. The market of London is open to the world, while those of the other colonies in Australia are protected by different amounts up to £5 a ton. The values of our sugars on the local wharf may be said to range from £10 10s for best whites and £13 10s for bright yellows downward. Very low grade sugars are practically without value here, and usually go to London. The prices being so low the latter place is also the destination of a good deal of the yellows this year, where prices up to £17 a ton are expected to be obtained. The Colonial Sugar Refining Company, referred to above, is purchasing or making over 23,600 tons of the colony's output of 64,000 tons for the purpose of refining, and pays £11 15s without deductions for 88 per cent sugar on the local wharf.

Those selling to this company are probably getting the best values for their sugars, but it will be readily understood that at such a figure the margin of profit is woefully small.

I think I mentioned in a previous letter that an experiment was contemplated by some of the large estate owners in settling Italian farmers on their lands as cane growers. The matter has been discussed in Parliament, and it appears that some 300 men and women have been engaged in Piedmont and are now probably on their way out. These families are under agreement to work for \$15 a month and keep for two years, but a special clause is inserted by which the employer agrees to sell lands on long terms

to these men and to crush their cane for them. There are eighteen men due to come to this district and will be located on Havana estate. The scheme is not popular, and the politicians who have no responsibility are doing the best to stop the experiment before ever it receives a trial. They are not likely, however, to succeed, and pretty much the same may, I think, be said of the experiments.

The Australian farmers are, moreover, rapidly taking up the work of cane growing, some 50,000 tons of cane having been produced this year, while the amount for next year will show an increase of at least 75 per cent.

As I have said this year's results are proving disappointing. The density stands steadily at 10½ Banmó, but the crops are light, and though the forest land is producing somewhat richer cane, that from the scrub lands, a most important portion of the crop, only shows sucrose at a little over 14 per cent.

This, with us, is poor, as we have been accustomed to at least 16 per cent, but the season is chiefly accountable for it though some do assert that the quality of the cane grown here is steadily deteriorating. When we compare the results obtained by the best manufacturers our extraction is not very satisfactory. An analysis of second megass from cane showing 14.07 per cent sucrose betrays the fact that we still lose 4.90 per cent or in other words, our percentage of extraction is only 89.13 per cent. Even this result is not obtained in many of our smaller mills.

I note that Homeshush and Havana, the two largest factories in this district, have adopted an improvement in the method of applying maceration, so as to try and save more of the sugar. Hitherto the megass on leaving the first rollers was sprinkled by a perforated pipe with water and steam, but now it is proved advisable to further increase the heat of the megass, which hitherto, after the operation, stood at 180 deg. F. Under the present arrangement the megass travels from the first to the second rollers, at a slow speed, over a bed of perforated iron, the whole being enclosed and made steam-tight, except at the ends. As the megass travels through this enclosed space, steam enters into it from underneath, thus raising the temperature considerably. Already this plan has served to effect an appreciable saving, and unless already adopted by your millers would be well worth their attention. I may add that the proportion of water which should be used to the ton of cane in maceration has been found to be about seventy gallons.

As I do not know exactly the order of work in your sugar houses, your readers must excuse me if at times I give them stale news. I only profess to give Queensland information and to note the change here, even if they be a matter of history with you. Our ordinary plan hitherto in the mill has been to treat the juice in the clarifiers first, then enside, then clean and concentrate and subside again ready for the vacuum pan. Now the order is being somewhat changed. By an increase in the use of lime the first subsidence is made more complete and the cleaning pans are entirely unused at one mill, while they are used after the triple effect instead of before in another. In the latter, also, the juice is passed through bag filters between the first subsiders and the triple effect. It is more than probable that still further efforts will be made to clean the juice more thoroughly in the clarifier, as it is obviously the safest and wisest to get the dirt out of the juice as quickly as possible the moment it leaves the cane.

MERCURY.

[We add an extract from an Australian source.—Ed. T. A.]

THE QUEENSLAND SUGAR INDUSTRY.

A correspondent of the Melbourne *Argus*, writing from Mackay on the 15th of July says:—The evolution of the Queensland sugar industry on the lines I forecasted at the end of last year is now almost an accomplished fact. The strongest company engaged in sugar making in Australia—the Colonial Sugar Refining Company—has taken the matter in hand, and in this district, at any rate, have already made great progress. Doubtless the terms on which the Homeshush lands are being leased and sold to farmers have ere this been communicated to your readers; also the fact that the applicants have been so numerous that the company is already in a position to pick and choose its tenants.

The price to be paid for cane grown by these sellers may run as high as 16s. per ton, if a sufficient quantity is produced, thus bearing out a statement I made last year that a manager who could not make sugar at a profit with cane at 14s. a ton, and sugar £13 on the local wharf, was not worth his salt. It is now generally admitted that even with colored labor, cane can not be produced at less than 14s., and, consequently, when it can be obtained at that figure, minus all anxiety and risk, the mill owner is obviously at an advantage. The season on which we are now entering promises to be a fairly good one. The amount of sugar produced throughout the colony will be about the same as last year, the two principal districts, Mackay and Bundaberg, producing nearly, if not quite, 40,000 tons between them. This will leave the rest of the colony to contribute 20,000 tons. Owing to short plantings and the fact that little cane was left unharvested last year, it is believed that the output of this district will be considerably less than last year, but for next year the acreage under cane and the results will probably be equal to the best on record.

A noticeable feature in connection with the present season's operations will be the production by one of the central mills—with white labor only—of some 1500 tons of sugar, showing that Europeans have cultivated no less than 15,000 tons of cane. On all hands contracts are being let to Europeans for cutting, loading and carting same, the first two operations having been in the past looked upon as exclusively kanaka's work. There is no likelihood of a scarcity of white labor during the next six months, as large numbers of the men who by striking lost their usual employment in the western pastoral districts, have drifted here in search of work. Near one mill alone there are over 100 men camped and awaiting the commencement of crushing. Since the first of the year over 75 in. of rain have fallen, this being 5 in. over the mean annual fall. In the face of this it is hardly surprising that the cane should be somewhat backward, but during this month with the splendid weather we have lately been having, it will be ripe enough for harvesting.—*Queensland Planter and Farmer*.

"AN APPEAL TO TEETOTALERS."

To the Editor of the Manchester Courier.

Sir,—On the 27th ultimo you were good enough to admit into your columns a letter of mine entitled "W. E. Gladstone and Unadulterated Coffee." On the evening of the day referred to the "United Kingdom Alliance" held their great meeting in your city, on which occasion the Hon. John Merley made himself very conspicuous. The concluding sentence in my letter was:—

"The leaders of temperance alliances should first clear the non-alcoholic beverages of all abuses before they

exert all their energies to compel everyone to become teetotalers."

And it is with a wish to emphasise this advice that I now venture to ask you for a further portion of your space. Sir Wilfred Lawson, in his letter of "appeal" which you publish today, although you state it has not your sympathy, writes:—

"It is one of the glories of England that her citizens abound in good works for relieving the sick and afflicted."

Now, I should like to ask this "good" citizen whose fault is it that the labouring classes in our still glorious "United Kingdom" are utterly unable to obtain a cup of really genuine good coffee when they ask for it? There has recently been a somewhat heated discussion in the London and provincial press on this very subject. The *British Medical Journal* of the 7th instant, under "The truth about coffee," took it up vigorously with the view of upsetting any statement that

"Today, in all probability, ours is the only country where, by its tax laws with respect to the sale of coffee, the working classes are almost unable to procure it in a pure state."

The *Daily Telegraph* on the 10th instant, in an editorial occupying more than a column refuted the statements made by the editor of the *British Medical Journal*, and, in fact, made it "very hot" for him, as follows:—

"With regard to the adulteration theory, it positively asserts that pure coffee is more easily to be obtained in this country than in France, Austria, Italy, or Germany. Why this should be so, no reason does appear, and we confess ourselves unprepared to place implicit faith in so sweeping an allegation while totally unsupported by satisfactory evidence to its correctness. Even should it be conclusively demonstrated that coffee is purer in London than in Paris, or any other continental capital, we should only be compelled to avow our preference for the impurer article, inasmuch as it is unquestionably much more palatable than the genuine stuff as prepared for us in our own dear native land. This is a fact as thoroughly ascertained and unanimously recognised by travelled Englishmen that it carries conviction with it as to the superiority of the French, Austrian, and German methods of preparing coffee over our own. Yet the *British Medical Journal*, which certainly has the courage of its opinions, boldly asserts that we "all know how to make good coffee," which may be regarded as one of the most amazing statements ever put forward in the columns of a scientific periodical, but that "there is no one who cannot make it." Having pronounced these tremendous assertions, it straightway proceeds to disprove them, &c.

The *Standard* of the 12th inst. had also "a gem" of an article on this subject which ought to be dear to the heart of all "good teetotalers" like Sir Wilfred Lawson, who are only too anxious to be engaged in doing "good works for relieving the sick and afflicted." Here is a short extract from the article referred to:—

Good teetotalers are dismayed and distressed to find that the consumption of coffee is declining in Great Britain; but the fact may be explained, perhaps, by the sample of coffee Dr. Stokes has discovered containing not less than 70 per cent of chicory. A cup of good coffee ought to be quite as easy to get as a cup of good tea. Euhlish householders should buy the berry fresh, and fresh grind it in their own kitchens, and serve it hot, strong, and above all, transparent. The *Standard*, referring to the lost taste for "pure coffee" in England, concludes by saying:—

In time it may become the duty of food inspectors and public analysts to detect and punish the adulteration of chicory by means of coffee, and as the demand for the former gradually renders it more expensive, and the disease of the latter makes it a drug in the market, we shall, perhaps some day purchase a packet of somebody's pure chicory, which will turn out to be mixed with 70 per cent of coffee.

The *British Medical Journal*, in long editorial notes, again returned to the subject on the 14th and 21st instant, under the respective

headings of "Coffee as it is made in England," and "The Coffee Drinker's Lament." All the papers I have referred to do well worth reading, not only by "good teetotalers," but by "good citizens," generally, and particularly by promoters of such "glorious" institutions as "village clubs" referred to in your editorial of today. When it is remembered what Sir Andrew Clark (one of the ablest physicians of the present day) has lately had the courage to say with respect to the effect of "strong tea;" and what has appeared in the papers I have referred to with respect to the excellence of "pure coffee," as a stimulating beverage, there is every reason why we should have two strings to our bow, a demand sooner or later must be made upon our Legislature for an amendment of the present protected laws with respect to the sale of coffee to the people of the United Kingdom. In this connection, and in the interest of all concerned, I cannot refrain from calling public attention to the following extract from a letter, dated the 17th instant, received by me in reply to my inquiry from the secretary of the London Chamber of Commerce:—

"As regards the purity question, you are quite right in assuming that this Chamber was interested in the matter some years ago, when Mr. Gladstone's Bill, to which you refer was passed. We did all we could in Parliament to get the exact proportions of the different ingredients indicated on the labels. The President of the Chamber (at this time Mr. Maguinc, M. P.) brought in an amendment to this effect, but the grocery interest, which professed that no indication should be given, was too strong for us and we had to accept the compromise contained in the Act as it now stands."

That is to say, the great Liberal leaders of that time, the G. O. M. being then the head of the Government, by allowing free licence almost to the grocers in the sale of "chicory mixed with coffee" and sold simply as a coffee mixture, secured the grocers' votes, but drove the people of this country from coffee—anyway, it must be logically conceded, drove them more and more in the direction of the beer and whiskey taps—for, as Dr. Stokes, the public analyst for Paddington, states (see *Standard* of 12th instant):—

"The people have neither the time nor patience to read all the flummery which may be given away with a pound of coffee—the purchaser ought to possess a legal right to get what he asks for and pays for."

And yet these same astute Liberal leaders, who, not caring then one jot as to the consequences, entered into this disgracefully abominable arrangement with the grocers, are actually at the same game with the teetotalers, who are to solve their "Local Option" Bill passed, if they will, by their votes, in the meantime but consent to stop and act as a flunkey to the lover of the G. O. M. while he makes his second and, no doubt, final attempt to topple over the United Kingdom. Should he succeed, the story of Samson Agonistes will be repeated, only on a more gigantic scale, and W. E. G. will become—is this his little vanity?—a great historical personage for all time. Well, "good teetotalers," while listening to the voice of the charmer, will, I have no doubt whatever, remember, at a crisis like the present, that, though they are "good teetotalers," they are, first of all, GOOD CITIZENS.

Nov. 26th, 1891.

[The truth seems to be that preference is more and more given to tea from its greater cheapness, its more easy preparation and its freedom from adulteration. But all the same coffee ought to receive fair play by the proportion of chicory admixture being always stated on the packets.—ED. T. A.]

THE GRASS FAMILY,

BY H. C. C.

Midge came in from among the flowers, washed her hands, bathed her hot face, and as she heard the tea-bell, walked to the dining-room saying, "I am so tired of this horrid grass that I promised grandma to keep out of her flower beds. What's grass good for

any way? Now mother, I know you are going to tell me how my cow likes it, and how I like her milk; but that don't alter the fact that grass is always in the wrong place and somebody has work to get it out of the way. I believe the world could do very well without the grass family."

"I know a little girl who would be the first to object if all the grass family were banished," said Mrs Winter.

"Try me and see, mother."

"Very well, shall we begin now?"

"Yes ma'am, as soon as I get my bread and butter."

"Here is the butter, but I cannot give you the bread; it belongs to the large family you want to banish."

"What mother, this light bread?"

"Certainly, wheat is one of the grasses."

"Well, then, I'll take a muffin."

"Not now; the muffin is made of corn meal, and corn is another member of the grass family."

"Dear me, I don't like brown bread, but I'll have to fall back on that."

"No; the brown bread is made of rye flour. I have often heard you admire the fields of ryegrass."

Madge's face fell. She was very hungry after her scuffle with the grass among the flowers, and now it seemed the troublesome thing was about to get the best of her after all. With a doubtful look she handed her plate for a spoonful of rice; but again her mother refused; it was one of the banished grasses.

"Well, mother, you always get the best of me. I'll take back all I said. I begin to think we could not live without grass; but of course, I did not know such things as wheat and corn were grasses."

"They are the seed or fruit of grass."

"But, mother, they do not look alike. Why do you class them together? What is the coat-of-arms of this family?"

"In the first place, all these stems are culms—that is, jointed and hollow between the joints. Second, the leaves have open sheaths enclosing the stem at their base; and they are 'two-ranked,' the second leaf coming out half-way around the stem above the first, and the third leaf exactly above the first, the fourth above the second and so on; and all have parallel veins. Third, each flower is enclosed in a glume or husk. Fourth, they are all endogenous."

"That means inside growing," said Madge.

"Yes; there are no layers, but the wood and pith is all mixed in together as you will see if you cut across a corostalk."

"Why, mother, all the bread we eat is made from the grass family."

"Yes, and the oatmeal, wheat gorm, hominy, grits, barley; and besides that they furnish nearly all the food for cattle. The great loads of hay, the barns full of timothy and orchard-grass, all come from your banished family. And there is one you are especially fond of, and drink its juice as readily as Daisy does that from the sweet hay."

"I may chew gum, but I never chew grass stems for their juice, mother."

"How about the sugar-cane?"

"Of course, I suck the juice from that. Surely that is not a member of the family?"

"Look at the coat of arms and see."

"Yes; I know it has a jointed stem with wood and pith mixed together. The leaves grow in two ranks, and are parallel veined, and form a sheath around the stem. Is the root fibrous?"

"Yes; there is no long tap root, and the flowers are enclosed in little, scaly bracts, or glumes. This cane is an important one of the grasses. Nearly all the best sugar of the world comes from it. Your candy-shops would have to close, and no more cane-syrup for that sweet tooth of yours. No more pop-corn balls, either."

"What, mother, how is that?"

"Only that the sugar comes from the cane and the pop-corn like your bread-corn, is first cousin."

"The corn and cane are the largest of the grass family; and they not, mother?"

"No; there is a distant relative in tropical countries which grows much larger, the bamboo. It runs

up from fifty to eighty feet high, and the hollow-jointed stem is ten inches thick—as large as your body. It is a beautiful plant and very useful."

"Do they grind up the seed for bread as we do corn?"

"No; only the young, tender shoots are used for food, but almost everything is made of the stem—baskets, water-pipes, nubbrellas, fishing rods, baskets, hats, furniture, ropes, and paper, and so on."

"Oh, yes, and I have seen the walking-canes made of bamboo. Which of all the grasses is the most useful?"

"Rice furnishes food to more people than any, for the people of China and India live almost entirely on rice. Corn and wheat are used more in this country."

"Do none of the grasses have pretty flowers?"

"No, perhaps not; but the feathery plumes of the panpas grasses are as beautiful as flowers."

"Why mother," said Madge, as she made a survey of the table, "not one thing on this tea table but what is made from the grass family except the butter; and I suppose you would tell me that Daisy could not give us that if there were no grass. Well, I'll not say anything more against the grass family, only I wish it bore pretty flowers of its own, and did not take such delight in choking grandmother's."

"The plants that feed the world do not need beautiful flowers to make them valuable any more than the great oak, and elm, and chestnut trees do. And if the grass did not spring up so easily, food would be harder to get. Flowers are a luxury, and all luxuries must be paid for in work or money. When you grow weary of pulling the green blades from among your flowers, you must remember that; and instead of despising the persistent grass, respect it the more because it so freely and abundantly gives itself for the food of the world. Think of a world without this grass family. The cattle upon a thousand hills would lie down famishing; flowers might blossom, fruits ripen, but without bread, the staff of life is gone, and man would soon lose strength, and hope, and life."—*U. S. Paper.*

CINNAMOMUM—CINNAMON.

The inner bark of the shoots of *Cinnamomum Zeylanicum*, Breyne (Ceylon cinnamon); or the bark of the shoots of one or more undetermined species of *Cinnamomum* grown in China (Chinese cinnamon). Nat. Order Lauracea. Generic character. Flowers hermaphrodite or polygamous, panicled or fascicled, naked. Calyx six-cleft, with the limb deciduous. Fertile stamens, nine in three rows; the inner three with two sessile glands at the base; anthers four-celled, the three inner turned outwards; three capitate stamens next the centre. Fruit seated in a cup-like calyx. Leaves ribbed. Leaf buds not scaly (Lindley). Habitat, Ceylon; cultivated.

CEYLON CINNAMON is in long, closely-rolled quills, composed of eight or more layers of bark of the thickness of paper; pale yellowish-brown; outer surface smooth marked with wavy lines; inner surface scarcely striate; fracture splintery; odor fragrant; taste sweet and warmly aromatic.

CHINESE CINNAMON (osmia bark) is in quills about one-twenty-fifth of an inch (one millimeter) or more in thickness; nearly deprived of the cork layer; brown; outer surface somewhat rough; fracture nearly smooth; odor and taste analogous to that of Ceylon cinnamon, but less delicate.

CEYLON CINNAMON.—The bark was originally collected from the tree in the wild state, but the Dutch introduced the practice of cultivating it. The principal cinnamon gardens are in the vicinity of Colombo. The cinnamon harvest commences in May and continues until late in October. The tree mentioned above is variable in size, but is usually of small stature. In favorable situations they attain the height of five or six feet in six or seven years. The bark is

* Error: in times of scarcity bamboo seed have been eaten in India.—Ed. T. A.

† The cultivated cinnamon is coppiced, and many of the shoots make a growth of over six feet in eighteen months.—Ed. T. A.

Sorted into three qualities, distinguished by the designations of first, second and third. The inferior kinds are used in the preparation of the oil of cinnamon.*

CHINESE CINNAMON (cassia bark). Immense quantities of cinnamon are exported from China, the finest of which is little inferior to that of Ceylon, though the mass is much coarser. It generally comes loose or packed in bundles with bands of bamboo. The pieces vary considerably in length and are either curved or double quills of one-fourth to one inch in diameter, and have a smooth or finely-wrinkled, reddish-brown outer surface, marked with some dark leaf scars, occasionally with light colored lines, and very generally covered with larger or smaller irregular patches of bark.

SALON CINNAMON, of late occasionally met with, is in regular unscrapped quills, yields a darker colored powder, but has a very sweet and warm cinnamon taste.

CASSIA LIONEA is a term sometimes applied to inferior varieties of Chinese cinnamon, which has a thicker bark and but slight cinnamon odor and taste. The origin of these barks is not positively known.†

CAYENNE CINNAMON has a reddish tinge, and is usually thicker, being collected from older branches, but when gathered very young is so rarely distinguishable from Ceylon cinnamon.

Sometimes cinnamon from which the oil has been distilled is fraudulently mixed with the genuine. It can be detected by its greater thickness and coarseness of fracture, and the deficiency in the peculiar sensible properties of the spice.—*Pharmaceutical Era*, Nov. 15th.

CEYLON'S PREMIER TEA COMPANY.

AN IMMENSE OUTFURN FOR THE YEAR.

We learn, on enquiry, that the total outturn of made tea from the factories of the Ceylon Tea Plantations Company during the year 1891 was 4,291,584 lb. which, so far as we know, beats the record of any one company for both India and Ceylon. We have no Indian statistics for the year 1891, but in 1890 only two Indian Companies approached this amount, viz, the North Sylhet and South Sylhet Companies, which each produced 4 millions lb. Comparing the Ceylon Company's figures for 1891 with the leading Indian companies for 1890, the result is as follows:—

	1891	1890
Ceylon Tea Plantations Coy.	4,291,584	4,000,000
North Sylhet Coy. (estimated)	4,000,000	2,731,200
South Sylhet Coy. (do.)	2,731,200	2,334,790
Assam Coy.	2,334,790	
Land Mortgage Bond		

If either of the two Sylhet companies beat the outturn of the Ceylon Tea Plantations Company for 1891 we shall be surprised to hear it. The increase of tea manufactured in the factories of this Company during the year is about proportionate to the increase for the whole island, as the following figures testify:—

	1890	1891
Ceylon Tea Plantations Coy.	2,939,768	4,291,584
do do	4,291,584	

The excellent prices obtained for the tea manufactured by this Company, the low cost of production, and the efficient manner in which all their estates are worked, reflect the greatest possible credit on all the superintendents concerned, and especially upon Mr. G. A. Talbot, the General Manager, who is to be congratulated on the magnificent outturn from the estates under his charge.

* Of late years a fourth class has been added in the shape of chips, to the great lowering of prices. A large proportion of the chips formerly distilled into cinnamon oil are now used in lieu of the haled spice, chips being about the equivalent of dust in the case of tea.—*Ed. T. A.*

† Mr. Ford, the Hong Kong Government botanist, has carefully examined and described the China cinnamon.—*Ed. T. A.*

THE COMPANY AND COFFEE PLANTING IN THE STRAITS.

At a meeting of the shareholders of the O. T. P. Company held in London on January 6th (the day before yesterday), it was decided not to take up land in the Straits for coffee planting—a decision which is, under the circumstances, a very wise one we think.—*Local "Times,"* Jan. 8th.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, Dec. 19th.

CINCHONA.—The last cinchona auctions of the year were held on Tuesday. They were of fair extent, the number of packages offered being:—

	Pkgs.	Pkgs.
Ceylon	767 of which	654 were sold
East Indian	775 do	693 do
Java	55 do	55 do
South American	447 do	333 do
Total 2,044		do 1,734

There was no quotable alteration in the prices upon last auctions, though perhaps the tone, generally speaking, was a shade less firm during the latter part of the auction. The average unit may be quoted at 1 l-18ths d per lb.

The following are the approximate quantities purchased by the principal buyers:—

	Lbs.
Agents for the Menahelm and Amsterdam works	102,877
Agents for the Frankfort O/M. and Stuttgart works	69,910
Agents for the American and Italian works	62,691
Agents for the Auerbach works	42,945
Messrs. Howards & Sons	35,931
Agents for the Bruswick works	4,247
Agents for the French works	2,210
Mr Thomas Whiffen	2,090
Sundry druggists	24,879

Total quantity of bark sold	347,810
Bought in or withdrawn	74,042

Total quantity of bark offered	421,85
--------------------------------	--------

SOME ACCOUNT OF THE NUTMEG AND ITS CULTIVATION.

BY THOMAS OXLEY, ESQ., A. B.,

Senior Surgeon of the Settlement of Prince of Wales' Island, Singapore and Malacca.

(From the "Journal of the Indian Archipelago and Eastern Asia.")

(Concluded from page 484.)

In addition to keeping the trees clean and free from moss and parasitical plants, it is highly desirable to use freely the pruning knife, cutting away all perpendicular shoots, the decayed ends of branches, or whenever the verticles are too close thinning them to admit air and sun to the centre. From over bearing, poverty of soil, or lodgement of water, it frequently happens that the top of the tree withers and the whole of the plant will soon follow, unless it be cut down below the affected part; if this be done in time it generally saves the tree which after a few months will throw a shoot from the hard wood of the stem to replace the former loss. Young plants are all the better for having the two or three first series of verticles cut off, otherwise the tree becomes too shrubby and the lower branches touch the ground excluding air, forming altogether a very inferior plant. This practice would however be unsafe in places like Penang affected by droughts, unless the plants be kept well shaded, until the upper verticles are sufficiently large to afford protection to the roots. As the tree bleeds freely upon being cut, the pruner ought to take along with him a pot of cement formed by boiling together two parts of pounded chalk and one of vegetable tar, which applied warm stops the run of the sap, gradually hardens and will remain on the cut part until it be quite healed. I have seen it stick on for several years resisting all weathers.

Some trees from receiving too great a check are apt to overbear, and will soon wear themselves out if not watched and relieved of their superabundant fruit. This ought to be done so soon as the fruit forms and if permitted to remain until three

fourths grown the mischief is already effected and cannot easily be remedied, but even should the tree not perish, the crop will scarcely be worth the gathering so inferior will be the quality and the tree unable to perfect its fruit, which splits ere the mace is red and while the nut is soft and good for nothing. Unhappily some trees have a habit of splitting their fruit untimely although their general appearance indicates strength and vigor. This is a fault for which as yet I know of no remedy; I attribute it to an original fault in the seed, and if this be correct I fear it admits of none.

The planter having his tree arrived at the agreeable point of producing, has but slight trouble in preparing his produce for market. As the fruit is brought in by the gatherers, the mace is carefully removed, pressed together and flattened on a board, exposed to the sun for three or four days, it is then dry enough to be put by in the spice house until required for exportation, when it is to be screwed into boxes and becomes the mace of commerce. The nutmeg itself requires more care in its curing, it being necessary to have it well and carefully dried ere the outer black shell be broken. For this purpose the usual practice is to subject it for a couple of months to the smoke of slow fires kept up underneath, whilst the nuts are spread on a grating about eight feet above. I myself prefer one raised fully 10 feet, but the model of a perfect drying house is easily obtained, and the process is too well known to require any further explanation. The only caution I would give is that planters ought to take care and not dry their nuts by too great a heat as they shrivel and lose their full and marketable appearance; for this purpose I think it desirable to keep the nuts, when first collected, for eight or ten days out of the drying house, exposing them at first to an hour or so of morning sun, and increasing the exposure daily until they shake in the shell; the nuts ought never to be cracked until required for exportation or they will be attacked and destroyed by a small weevil-like insect, the larva of which is deposited in the ovule and, becoming the perfect insect, eats its way out, leaving the nut bored through and through and worthless as a marketable commodity. Lining the nuts prevents this to a certain extent, but lined nuts are not those best liked in the English market, whereas they are preferred in that state in the United States. When the nuts are to be lined it is simply necessary to have them well rubbed over between the hands with powdered lime. I am given to understand that they are steeped in a mixture of lime and water for several weeks by the Dutch mode of preparation. This no doubt will preserve them, but doubtless it must also have a prejudicial effect on the flavor of the spice. After the nuts are thoroughly dried, which requires from six weeks to two months' drying, they cannot be too soon sent to market. But it is otherwise with the mace, that commodity when fresh not being in esteem in the London market, seeing that they desire it of a golden color which it only assumes after a few months, whereas at first when fresh it is blood red; now red blades are looked upon with suspicion, and are highly injurious to the sale of the article. This is one of those peculiar prejudices of John Bull which somewhat impugn his wisdom, but it must be attended to, as John is ever ready to pay for his caprice; therefore those who provide for him have no right to complain although they may smile.

Through the kindness of the Resident Councillor I have been furnished with the following correspondence and statistics which show that the nutmeg tree was sent from Bencoolen to Singapore the latter end of 1819, so that twenty-nine years have elapsed since its first introduction. Some of the plants alluded to in Sir Stamford Raffles' letter were set out at the foot of Government Hill in neither a bad soil nor locality, and several of them are at present and have been for the last ten years fine fruitful trees. Table No. 1 shows that 315 trees in this garden yielded last year 190,426 nuts or at the average of 604 for each tree, but of the 315 bearing trees mentioned in the table not over fifty are of the old stock, most hav-

ing been planted since 1836, so that a Planter may safely calculate on having a better average than is here set forth, provided he attends to his cultivation and his trees are brought up to the age of 15 years. If a plantation be attended to from the commencement, after the manner I have endeavoured to explain, and the trees be in a good locality, the Planter will undoubtedly obtain an average of 10 lb. of spice from each tree from the 15th year. This at an average price of 2s. 6d. per lb. is 25 shillings per annum. He can have about 70 such trees in an acre, so that there is scarcely any better or more remunerative cultivation when once established, but the race is a long one, the chances of life, a high rate of interest in this country make it one of no ordinary risk, and it is one that holds out no prospect of any return in less than 10 years. A person commencing and stopping short of the bearing point either by death or want of funds will suffer almost total loss, for the value of such a property brought into a market where there are no buyers must be merely nominal. Again if the property has arrived at the paying point, almost any person of common honesty can take charge of and carry it on, for the trees after 12 years are remarkably hardy and bear a deal of ill treatment and neglect; not that I would recommend any person to try the experiment, but it is some consolation for the Proprietor to know that stupidity will not ruin him, and that even at the distance of thousands of miles he can give such directions as, if attended to, will keep his estate in a flourishing and fruitful state.

I have now set the pros and cons of nutmeg cultivation before the reader. Should he like to try the experiment there is ample scope and verge enough for him in Singapore. He need not be afraid of failure if he proceeds with energy and perseverance. The cultivation, as will be seen by the appended tables, is rapidly extending, and I fear the prices are falling. Should the Moluccas be thrown open I cannot answer for how much greater may be the depreciation in value, but a produce that requires 15 years to bring it to market in remunerative abundance is not so easily overdone. The tree is not more quickly productive in the Island of Banda than in the Straits, and, as I have before said, neither do they excel us in relative quantity or quality. Those who have established plantations may laugh at the bugbear of over production and rest content even with some further reduction in prices.

The consumption is increasing and likely to increase in the United States, and no doubt were the heavy duty exacted in England lightened, the consumption would also increase in Great Britain. At present the duty is above the value of the article, which is anything but encouragement to our eastern colonies, and is hardly fair considering that the differential duties have been done away with and that we have to compete on equal terms with our monopolizing neighbours the Dutch, who take very good care to make no reciprocation in favor of British commerce.

To Major FARQUHAR,

Resident and Commandant, Singapore.

Sir,—Enclosed, I transmit a list of Nutmeg and Clove Plants this day shipped on the "Indiana" for 100 Nutmeg Plants, in 8 boxes } Singapore, and put
100 Clove do. in 3 do. } under the immediate
1000 Nutmeg seeds, half of them } charge of Mr Damm,
in a double row. } who is proceeding
350 Clove ditto. } thither on the same
25 Large Nutmeg plants and } ship.
the same number of Cloves. } You will be pleased
to report the condition in which these Plants are
received, and to exert your utmost endeavours to
establish the cultivation under your immediate
authority.

I have &c.,
(Sd.) T. S. RAFFLES.

Fort Marlbro', 18th August, 1819.

To the Hon'ble Sir STAMFORD RAFFLES, Kt.,
Lieut.-Governor, &c. &c., Fort Marlbro'.

Hon'ble Sir,—I have the honor to acknowledge the receipt of your letter dated the 18th August covering

a list of Clove and Nutmeg Plants shipped on the "Indiana" under charge of Mr. Dunn, and have much pleasure in informing you that the whole have been landed safe and in good order.

The larger plants have been regularly planted out where it is intended they should remain, and the seed and smaller ones put in nursery beds for the present, the whole are in a thriving state,—you may depend on every possible attention being paid to the cultivation of Spices, and I consider myself fortunate in having Mr. Brooks, a European Gardener, here, whose services will be very useful in superintending generally the Spice plantations, and propose to allow him a monthly salary of 40 Spanish Dollars until your pleasure is known on the subject.

I have &c.,
(Sd.) W. FARQUHAR,
Resident.

Singapore, 28th Oct 1819.

PLANT COLOUR AND SOIL COMPOSITION.

Mr. George Villo startled the world some years ago with his suggestion "that plants can absorb free nitrogen." He now comes forward with an equally pregnant notion "that the varying tints of green,

which plants assume, is an indication, which may be turned to practical account by agriculturists, as to the chemical deficiency of soils. This idea is well worthy of the attention of Trinidad planters, and especially with regard to coffee and cocoa. We all consider that a dark green in those plants indicates a perfect soil and perfect plant growth; now Mr. Villo says that any departure from this standard shows, according to shade, the chemical ingredient wanting, e.g.

1. Light green = Want of phosphoric acid.
2. Very pale green = Want of potash.
3. Yellow green = Absence of nitrogen.

If this is true the planters will have a practical and ever present test, and one which will perhaps tell them more than Chemistry or Science can do. No one, of course, disparages the service of the Agricultural Chemist with regard to soils, but it is the same with soils as with horses—Anatomy and Physiology can no more tell you everything about a horse than Chemistry can tell you about a soil; but in studying the proposition of Mr. George Villo two corollaries must be borne in mind (in tropical agriculture). 1. How may the plant-colour be affected by exposure, by stones and other mechanical causes? 2. What relationship is there between the darker shades of green of coffee and cocoa and their fruit-bearing qualities.—Trinidad Agricultural Record.

COFFEE ENTERPRISE IN TRINIDAD.

As to its impracticability and the unprofitableness of our soil and climate we have direct evidence to the contrary wherever we turn. Our native coffee, although badly kept, and mostly planted together with cocoa, is everywhere healthy, vigorous, and yields, it is no exaggeration to say, over 1 lb. a tree on good lands; Mr. Prestoe I believe estimated it at double that amount. The question of altitude was raised by the Hon'ble Mr. Laugel at the last meeting of the Central Agricultural Board, and it is a very important point: the fear is that any considerable area planted a little above sea level will be exposed to the coffee leaf disease which occurred in Dominica some years ago. Mr. Morris, of Kew, thinks we should go in for Liberian on low levels; but unfortunately we don't yet know quite how it might suit our climate and soil. The object of using this rather awkward plant, which ripens too slowly, pulps badly and was formerly quoted so low in the markets, although in the general coffee rise of late it has touched 100s.—is that it is supposed to resist the leaf disease (?). They are now pushing it (on Mr. Morris's advice) in Dominica, and they are giving it a fair trial also in Sriniam. In the last named Colony they are making some interesting experiments with grafting, viz:—

1. Liberian on Liberian.—To hasten and improve bearing and to dwarf the tree.
2. Liberian on Arabian.—The same object.
3. Arabian on Liberian.—To strengthen the vegetative growth of the first named and render it less subject to disease, etc.

These experiments are in course of observation, so no conclusion can be drawn at present, but it would be wise, here, to start a mixed cultivation; at the same time we must bear in mind that we lying much nearer to the equator, and almost forming part of the mainland of America, have very different climatic conditions to either Jamaica or Ceylon, and it is possible that with full and appropriate shade such as the Cachiman, (Grand's bois) Poixdoux, Avocado, etc., we may have no cause to mistrust the Arabian or Mocha Hybrid (the latter is a most promising plant). Baron Eggers thinks the altitude a matter of secondary importance with us, and states that the best coffee estates in Venezuela have not an altitude of more than 300 or 400 feet above the sea level. The same thing obtains in the Brazils I am informed, where coffee grows nearly down to the sea shore in some places.

Coffee has nearly died out in Southern India, Java and Ceylon, and men who recognize the importance of this great staple have been hunting out North

Borneo and every part of the East and they have tapped Africa in different regions with the view of finding a suitable soil and climate. The latest enterprise is the expedition of Sir Alfred Dent, organized in London, to explore the Peruvian Andes with the same object, the Peruvian Government having given extensive tracts of land and concessions on account of their failure to meet their engagements towards their bond-holders. In these wild regions, without any roads or good Government, there is of course no labour, but that is no object where such mighty interests are concerned. These enterprising planters propose to introduce Chinese. Should not this open our eyes to the bright future coffee offers us in our fertile island (?) where we have a stable Government and labour in abundance?

Another very important consideration for coffee growers here is the recent discovery of rich phosphatic deposits (organic) at Gasparillo. Some specimens recently examined have proved to contain no less than 90 per cent., and in its present condition (without being treated chemically) it has proved valuable as a manure to garden vegetables.—*Trinidad Agricultural Record.*

J. F. KELLER, of Licking county, Ohio, in an article communicated to the *National Stockman*, correctly remarks that experience teaches that all farm crops are highly benefited by being planted in a compact soil, though the degree of compaction depends to some extent on the nature of the soil. Very heavy clay soils need less compacting than some others of a lighter nature, as there is some danger of heavy soils becoming (in case of much rain) too hard if compacted to the extent that light soils will always require. On the writer's farm (which is clay loam) no crop is planted until the soil is first compacted by rolling once, and in some instances twice, with a heavy cast-iron roller.—*Indian Agriculturist.*

THE NILGIRI PLANTERS.—It has been a frequent source of annoyance to planters on the Nilgiris that they have been grouped with ordinary native ryats and land-holders, and made to pay their revenue or kistbandi in four equal instalments annually. The inconvenience of this system was often represented by the planters individually, and also by the Kotagiri Planters' Association; but their proposal to pay their revenue in one lump sum has hitherto not met with the approval of the Revenue authorities. Their chief objection to broken payments were (a) that a single payment in March was already sanctioned in the case of mixed puttahs; and (b) that few planters kept any large amount of cash in hand, but drew funds from the Banks as occasion required, and therefore felt it inconvenient to pay the Government demand in small sums. As a rule, the payment of land revenue by instalments is utterly unsuited to the conditions of planter life, and as planters are unable to adapt their financial arrangements to the kistbandi system, the repetition of small demands causes much irritation and friction. Taking these circumstances into consideration, and the almost general desire of all the European planters for a lump payment annually, it is under contemplation, as an experimental measure, to allow pottahdars who pay a land revenue of not less than R50 per annum, to pay the amount of their kistbandi in one sum on the 10th March, the concession being liable to be withdrawn if default is made in any year.—*M. Mail*, Dec. 29.

THE half-yearly meeting of the British North Borneo Company passed off with more unanimity than has been the case at similar gatherings during the last two years. As no criticisms were offered upon the very complete and interesting statement

which the Chairman made, it may be assumed that the shareholders were satisfied the directors had done the best that was possible in the circumstances, and that their general policy meets with approval. The retirement of Sir Rutherford Alcock from the chair for reasons of health was not the least important incident of the meeting, and we believe every one connected with the company will regret that Sir Rutherford has been compelled through advancing years to vacate his position as Chairman at a time when it may be said the undertaking he has devoted so much of his time and attention to has weathered the hard times a company of this nature has to contend with in its early days, but which has an assured future before it. The expressions of regret with which Mr. Richard B. Martin, his successor in the chair, accompanied his announcement of the fact met with a ready response on the part of all present. It will be gathered from the report of the proceedings that the directors, while curtailing the expenditure as far as possible, are fully alive to the importance of pursuing a bold and progressive policy in the administration of the company's affairs. The Chairman struck the right note when he deprecated a cheese-paring policy which for the sake of securing a temporary profit might retard the proper development of the country. The advice, too, which he gave the shareholders to support, as far as was in their power, the subsidiary companies as likely to promote the success of their own undertaking was practical, and will not, we hope, have been given in vain. We are glad to note that amongst other projects the establishment of a bank—long contemplated—is taking shape, and the Chairman was also in a position to announce that the railway matter is progressing well. The biggest cloud at the present time is, of course, the disturbance of the tobacco market. But there is every reason to think that the crisis is only temporary; and, as it is now fully demonstrated the Borneo can grow the class of tobacco which is most in demand for "covers," when the American buyers come into the market again the prospects in this direction will undoubtedly improve.—*L. and C. Express*, Dec. 18.

SIR SAMUEL DAVENPORT, K.C.M.G., gave an address on the "Olive," in the cultivation of which he has taken great pains, and in the value of which he is a great believer. The whole address was very interesting and instructive. He said the wealth of a country depended on its produce of an exchangeable value. The natural home of the olive, he said was the home of the vine, and (South Australia was peculiarly adapted for its growth. He quoted figures to show how well olives had paid. In 1890 olives from 1000 trees weighed 26½ tons, about ½ cwt. per tree. Some were young trees. The olives realised £212 9s, or 4s 3d a tree. The total working expenses were £104 13s 10d, the net return being £107 15s 2d. Planted 27ft. apart sixty trees could be put to the acre, and 100 would take sixteen and one-third acres, and the net profit would be £6 12s per acre and 2s 2d per tree. The returns compared well with returns from French and Italian vineyards. South Australian oil brought more than any other because of its purity and richness, and gave an eight times better return than wheat. Olive cultivation was equally profitable to the growing of good vines. South Australian olive oil was the purest and richest obtainable. There were several excellent varieties of European olives cultivated in South Australia. He had thirty-four varieties. The olive required technical knowledge and care. Few countries were so well off as South Australia with regard to sun and natural richness of soil. More technical knowledge was wanted.—*Indian Agriculturist*,

THE EXPORT TRADE OF CEYLON
FOR TEN YEARS :

TEA FROM ITS FIRST APPEARANCE IN 1873.

The Customs figures and those of the Chamber of Commerce for the export of tea from Ceylon in 1890 differ by more than a million of pounds. The Chamber of Commerce table shows the enormous export for the last week of the year of 3,793,687 lb., or more than the quantity opposite most of the months of 1890. The result of this addition to previous figures is to bring up the total for 1891 to the large sum of 68,274,420 lb. The discrepancy may be due to the fact that only completed cargoes of ships which have sailed are included in the one case, while daily shipments are included in the other. If the Chamber of Commerce figures really represent the quantity taken away from the island, they largely support the guess we at one time hazarded that the exports of 1891 would closely approximate to 70 millions of pounds. The quantity consumed in the island would go far to make up a total crop of 69 millions lb. for 1891. The figures in our Directory which represent the history of the enterprise from the first small quantity sent away in 1873 are those of the Customs, and to those previously given we now add the figures for 1891. This done, we get the following phenomenal advances :—

Year.	Packages.	lb.	Rs.
1873	2	23	58
1874	4	462	1,600
1875	4	1,438	2,402
1876	7	757	1,967
1877	—	2,115	3,457
1878	—	19,867½	20,900
1879	—	95,969	85,229
1880	—	162,576	150,641
1881	—	318,157	322,593
1882	—	697,268	591,805
1883	—	1,095,768	916,172
1884	—	2,392,973	1,435,784
1885	—	4,374,722	2,542,269
1886	—	7,849,888	5,162,427
1887	—	13,831,037	8,307,431
1888	—	23,820,723	12,924,490
1889	—	34,315,632	17,859,810
1890	—	45,709,518	22,999,759
1891	—	67,021,777	33,510,888

As the two packages in 1873 seem to have been separate from the 23 lb., we suppose we may take R58 value as representing a like number of pounds of tea. The results are that in 19 years the export of tea from Ceylon has risen, by leaps and bounds latterly, from 58 lb. valued at R58 to 67,021,777 lb. valued at no less than R33,510,888. This is still more than a million of rupees below the value reached by coffee in its culminating glory; but then there was no sudden rush upwards in coffee as there has been in tea, the annual value of which is likely soon to leave the highest figures ever attained by coffee far behind. In the table showing the distribution of our teas the Chamber of Commerce figures are used. The vast proportion of our exports, 63,745,000 lb. went to Britain, of which between 1,500,000 lb. and 2,000,000 lb. were re-exported to countries on the continents of Europe and America, leaving 61½ millions for consumption (about 53 millions in 1891) and to go into stock. Our second great customer is Australia, peopled mainly by men of the British race, whose acquired taste for China tea had to be combated and overcome. The fight was a hard one at first, as we personally know, but the progress recently in demand for our teas has been great and gratifying, the export having risen from lb. 2,560,000 in 1890 to 3,210,000 lb. in 1891. There can be little doubt, therefore, that Ceylon tea will replace China tea (the consumption of which has reached to over

20 millions of pounds) in the Australasian markets, as it has done in Britain. The markets of the United States and Russia—next to Britain, the greatest tea-drinking countries of the world—seem much more difficult to affect, by changing the taste of the tea drinkers. Hence the wisdom of the contemplated Chicago crusade and of every effort which can be made for the much more difficult conquest of the Russian market. At present our exports direct to America are represented by 163,000 lb., a fall from 204,000 lb. last year. To Russia we sent direct only a miserable 11,000 lb. To both countries (America including Canada) there were exports of our teas from Britain, but only to a small though promising extent. China took of our teas almost exactly the same quantity as America got direct, while India took no less than 620,000 lb. most of it for the Persian Gulf, no doubt. In the case of China and India there have been considerable increases on last year, and so indeed to Germany, France and other countries on the Continent of Europe; but as yet only about 1½ million pounds of our teas are taken by other than countries peopled by the British race. All this will ere long be changed, however, to the benefit equally of those who consume and those who produce Ceylon tea.—As regards total exports of tea in the year on which we have entered, we can have no desire for the recurrence of the meteorological conditions which resulted in flushes so overwhelming during a portion of last year that they could not be properly overtaken by the curing processes. But there can be little doubt that the total export of 1892 will be little, if at all, short of 90,000,000 lb.; and we trust the demand for our teas will expand in proportion. To secure this, attention must be earnestly devoted to upholding the reputation of the Ceylon product for quality,—for retrieving indeed the good name which some of the teas sent away in 1891, so seriously endangered.

The history of coffee and cinchona in the past ten years has been very different to that of tea. The course in both cases has been downwards, the export of coffee having fallen from 463,000 cwt. to 86,000 cwt.; while cinchona, after having risen from 440,000 lb. in 1882 to 14,838,000 lb. in 1886, has gradually decreased to the still huge quantity of 5,679,000 lb. Both articles are likely to shew still further diminution, unless the disappearance of leaf fungus and green bug, leads to a return by planters to their first love. In 1873, when only a few pounds of tea appeared in our exports, the quantity of coffee sent from our ports was 951,591 cwt. valued at £4,220,750 sterling. Cacao has, with some fluctuations, risen from 1,090 cwt. in 1882 to 20,532 cwt. last year. Conditions of soil and climate are likely to prevent any large increase in this article. For quality Ceylon cacao ranks first in the world; and we may say the same of the cardamoms produced in our island, the export of which has risen from 21,000 lb. in 1882 to 422,000 lb. in 1891. The once famous cinnamon of Ceylon, a pound of which at one time realized close on a pound sterling, is now down to the unremunerative price of about one shilling average. The gradual approach of this state of things has not hindered increased exports, which indeed must be largely the cause of lowered prices for a spice which is eminently a luxury. The figures for 1882 were :—

Baled bark	1,587,016 lb.
Chips	422,015 "
Total	2,009,931 lb.

From this quantity the rise in 1891 has been to

Baled bark	2,809,774 lb.
Chips	888,264 "
Total	2,898,038 lb.
Total 1882	2,009,931 "
Increase	888,107 lb.

The market has, in truth, been swamped with an article incapable of any very large increase, even by such lowered prices as the export of such large quantities of inferior bark and especially chips (equivalent to the "dust" of tea—scarcely equivalent indeed) have led to. Of this latter stuff which ought to have been distilled into oil or converted into manure, there has been an average export of over half-a-million of pounds during the ten years, while the baled spice has gone up from 1,587,000 lb. to 2,309,000 lb. The causes of the severe depression are manifest—excessive exports and lowered quality, quality in many cases on a level with China "casia," so that a reaction to diminished exports is inevitable; while to the cinnamon producers as to the tea producers of Ceylon the same advice must be given: "Sturdy quality rather than mere quantity." In coconut oil Ceylon well supports its claim of being the largest exporter in the world; and this is an article which is not likely to exceed the demand which exists for it, in Holland and Germany specially, for soap-making. The increase in the export of this article has been from 208,000 cwt. in 1882 to 409,000 cwt. last year—a doubled export. For this oil India and America are customers to the extent of 107,000 cwt. in the first case and 110,000 in the second.—Cupra, the dried kernels of the coconut from which the oil is expressed, leaving a valuable oil cake behind (known locally as ponnae), has fluctuated greatly; and the figures for last year show a fall more than equivalent to the increase in oil. The increased export of "desiccated coconut" used in confectionery may to some extent account for the decrease in cupra? The export of "ponnae" has increased in proportion to that of oil, the figures for last year, 192,210 cwt., being, we believe, unprecedented. The exports of coconuts fluctuate violently, the figures for last year being 6,699,000, against 11,908,000 in 1890. The export of coir rope, with some fluctuations, has ranged at an average of 10,000 cwt., but the increase in yarn and fibre, for the manufacture of mats, &c., some of the fibre being used in lieu of bristles, has been very important, yarn having risen from 66,803 cwt. to 90,699 cwt. and fibre from 7,959 cwt. to 37,897 cwt. Taken together the value of products of the coconut palm exported are of great value in our commerce, only second to tea indeed; with this grand difference between the two plants, that all but a fraction of the tea grown is exported, while most of the products of the coconut palm are consumed locally. "Desiccated coconut" is a marked exception; and the introduction and use of kerosene as an illuminant has set free from export a good deal of coconut oil which was formerly burned in the lamps of local houses, huts and boutiques. We now come to our next important mineral product (precious stones not reported except in rare cases), namely plumbago or graphite, of which in its finer forms, in large masses free from impurities, this island has almost a natural monopoly. Its very refractory character renders it exceedingly valuable in the shape of crucibles for the melting of the precious metals and the finer kinds of steel, such as is used for ordnance. The exports have fluctuated with "wars and rumours of wars," commencing in 1882

with 258,877 cwt., going down to 180,912 cwt. in 1884 rising again to the culminating figure of 475,516 cwt. in 1889, and closing last year with 400,268 cwt. Mining for this article and the search for sapphires and other precious stones are sometimes conjoined. The plumbago enterprise is far the less precarious. Heavy digging is necessary, but this strange mineral, the result either of carbonized vegetation or deposited, as a German savant thinks, from either gas or water, is more or less prevalent and plentiful over large portions of the western, and south end north western portions of Ceylon, its preparation and classification in Colombo afford employment to large numbers of men, women and children. The export of Ceylon ebony, under a restrictive policy adopted by the Forest Department, has gone down from a maximum of 23,951 cwt. in 1886 to a minimum of 3,539 cwt. in 1891. The one important dye-wood of Ceylon, sappan, has fluctuated and fallen, having shown an export of over 10,000 cwt. ten years ago, going down to 1,080 cwt. in 1889 and recovering last year to 2,577 cwt. Another dye substance, orchella weed, has fluctuated between 1,394 cwt. and 308 cwt., closing with 771 cwt. Kital fibres, used as substitutes for bristle, for brushes and for brooms, began with 1,496, cwt. rose to 2,771 cwt. in 1889, and closed with 1,889 cwt. The export of deer horns will probably decrease under the operation of recent laws directed to the preservation of game animals. The figures have varied from 2,375 cwt. in 1882 to 1,735 cwt. in 1891. The table closes with two essential oils, that from the lemon-scented grass, citronella, and cinnamon oil. The former, used chiefly to scent soaps, we believe, has assumed important proportions, the exports rising from 2,940,000 oz. in 1882 to 14,559,000 oz. in 1890 and 11,263,000 in 1891. It is regrettable if what we read, especially in American journals, be true, that this delicate product is not infrequently and not slightly adulterated with kerosene oil. The elegant cinnamon oil, obtained from the cells of the inner bark, in which alone resides the odour which poetry has imparted to "the spicy breeze," is not, we believe, tampered with. It was exported to the extent of 93,000 oz. in 1882, the export rising to 167,000 oz. in 1886 and closing at 122,835 oz. in 1891. The relative importance of our chief staples exports, now that coffee is no longer king, may be stated thus we believe:—TEA; PRODUCTS OF THE COCONUT PALM; COFFEE; Cinnamon; Plumbago; Cinchona; Cocoa; Cardamoms and minor articles. In present value and future promise, three articles seem to stand pre-eminent: TEA, which is KING in succession to coffee, abandoned; PRODUCTS OF THE COCONUT PALM; PLUMBAGO. Coffee, as we have indicated, may possibly revive, and minor industries may develop into importance. But the fortunes of the colony, doubtless, now and for years to come will be mainly dependent on the success of the tea enterprise. Increase of production is so assured that herein lies ground for anxiety and reason for every possible effort to promote increased consumption.

PROSPECTS IN WYNAAD.

OOTY, Dec. 20.—As I have visited Wynaad I write you a few lines, to give you the impressions which I have formed, as they are not altogether so entirely of the "has been" as our old friend who revisited the country lately wrote you of. That it is very sad to see so many large properties that we knew in the old time as flourishing coffee estates now overrun with lantern and jungle, must be allowed; but in writing of this deserted cultivation,

the flourishing condition of many of the coffee gardens and the very promising appearance of the new tea fields should not be forgotten. The terrible area of abandoned coffee is mainly to be attributed to the gold mania of the past decade. The companies that invested in Wynaad land for gold mining, looked on the cultivation of the surface as a very minor consideration. The coffee was worked on what was called commercial principles, and if for any reason the crop felt short of expectations, the expenditure in upkeep was proportionately reduced, and the unfortunate planter who was retained in the Gold Companies' service, to attend to the plantations, had no resource but to reduce the area worked in proportion to the allowance given, and thus nearly the whole gold country has reverted to its original jungle. Indeed, the two could hardly be worked together when the labour available was always requisitioned for the mining department whenever there was any scarcity of hands or press of work. But in private hands there are still well cultivated and paying coffee estates, and now with the high prices ruling, and a crop above the average, planters are doing well.

That King Coffee, as they call it in Ceylon, is on its last legs in Wynaad, is an exploded idea. Large fields of coffee were planted in Wynaad this last season, and men of experience from the famous Bambco District of Coorg are now opening extensively in Wynaad, and the beautiful young coffee, with various shade trees planted at the same time, delight the eye with their flourishing appearance, and recall days of the past, when every coffee plant seemed to thrive in any locality. Cinchona cultivation is now at a terrible discount, the market price of bark at a penny per unit of quinine, stops all idea of harvesting any but the richest bark, and the owner of a cinchona estate can only hope that his trees may outlive the enormous supplies from Java, and those trees that can do this will yet be a source of large profit.

Tea is doing well. The old seed bearing trees at Pandalar set at defiance the neglect of years, and when burnt down by jungle fire, rise again healthy as ever, like the Phoenix, while the young plantations of the last two years show such growth, that a planter of experience mistook a four-year-old Ledger field for Tea!! I suppose at some little distance. With the report on Mr. Pannott's tea that you lately published in your paper, there must be a great impetus given to this industry, as there is available in Wynaad a very special type of tea plant which appears to exactly suit the soil and climate, and produces a tea of most exceptional strength and flavour, which always commands a high price.—*Madras Times.*

THE AMSTERDAM CINCHONA AUCTIONS.

AMSTERDAM, Dec. 19.

At today's auctions 5,380 packages Java cinchona sold at a slight reduction in price, as compared with the last sales, the average unit not exceeding 5½ cents or about 1 1-16d per lb., which is on a par with this week's London auctions. The following was the range of prices:—Manufacturing barks in quills broken quills and chips, 7 to 75 cents (= 1¼d to 1½d per lb.); ditto root, 10 to 44 cents (= 1¼d to 8d. per lb.) Druggists' barks in quills, broken quills, and chips, 10 to 36 cents (= 1¼d to 6¼d. per lb.); ditto root, 12 to 19 cents (= 2d to 3¼d per lb.) The principal buyers were Mr. Gustav Bricgleb, the Amsterdam quinine-works, and the Brunswick quinine-works.—*Chemist and Druggist.*

THE DUTY ON TEA.

TO THE EDITOR OF THE "SYDNEY MORNING HERALD," Sir,—Now that the Government have proved a majority in their favour in the Assembly, I would like to point out the unfairness of the proposal to remit the duty on tea on so short a notice. The proposal has already brought business in this commodity to a standstill so far as the distributing trade is concerned

Every greener and storekeeper in New South Wales has ceased to buy, and will buy nothing before the 1st of March next unless he runs out of the article before that date: consequently the distributing houses, who are holders of large stocks of duty-paid teas, will find themselves losers on the 1st of March next of 3d per lb. on all their duty-paid stocks, besides the loss of three months' trade, which in itself is a very serious matter. The retail trade is not so hardly dealt with, as it will have three months to reduce stocks; but even amongst retailers there are numerous holders of large stocks—men who buy 12 months' supply on the arrival of the new season's teas, and have still six months' supply on hand. I would suggest to the Treasurer, under these circumstances, that in fairness to the trade in general and the distributors in particular, he should alter the date for remitting the duty to the 1st of August next, as at this date traders in tea in the ordinary course of business have their stocks worked down to minimum in view of the arrival of the new season's crop, and it would allow holders to get out without loss, and the disorganization of business which is inevitable if the 1st of March is the limit. This would also be an advantage to the Treasurer, as it would add so much more revenue to his accounts for the financial year. Trusting you will find space for this important matter,—I am, &c.,
 December 11th. DISTRIBUTOR.

STATEMENT SHOWING THE EXPORTS OF INDIAN TEA FROM BOMBAY PRESIDENCY, APRIL TO NOV. 1891.

(From Watson, Sibthorp & Co's Report.)

	Lb.
United Kingdom	17,322
Austria	2575
Malta	36
Spain-Gibraltar	2,750
Abyssinia	290
E. O. of Africa-Mozambique and Zanzibar	3,700
Egypt	500
United States	40
Aden	1,733
Arabia	26,592
Persia	1,286,315
Straits Settlements	50
Turkey in Asia	164,431
Australia	194

Total... 1,506,528

[The above export of over 1½ million of pounds in 8 months is described as "Indian tea," but query whether much of the Ceylon tea sent to Bombay is not included?—Ed. T. A.]

THE SAPPHIRES AND RUBIES OF SIAM.

The report of the directors states:— In the beginning of April Mr. Gibbons, the company's chief agent in Siam, paid his first visit to the mines, and selected an area of nine square miles, which embraced all the mines of Naveg and Chanak, in the province of Krat. The negotiations with the Government in connection with the formal transfer of the properties to the company were somewhat protracted, but towards the end of June Mr. Gibbons received permission from the Government to take over the nine square miles he had selected. He at once proceeded to Krat, and a month later he was able to report that he and his party were in peaceful possession of the mines. It then became necessary to decide upon a system of working the properties. The directors were opposed to any outlay being incurred for machinery until the value of the company's property had been proved, and Mr. Gibbons suggested as a temporary system that licenses should be issued to selected diggers on condition that all stones obtained by them were to be at once surrendered to the company's officers, their labour being rewarded *pro rata* with the value of the yield, such value to be fixed by the company's resident gem expert; it b

further understood that if a digger did not care to accept the company's prices he would not be allowed to dig within their selected area. These proposals were approved by the directors, and about the middle of August Mr. Gibbons commenced to register and issue licenses to those diggers who were willing to stay and work for the company. The majority of the men working at the mines at once agreed to the conditions imposed, and were granted licenses. Mr. Gibbons' illness somewhat delayed the despatch of stones, but at the end of September he was able to announce the shipment of a first consignment of 40,000 carats, and reported that monthly shipments might be relied upon. Cablegrams have since been received from him advising the shipment of two further consignments, one of 130,000, and another of 40,000 carats. Seeing that four months have not elapsed since the company commenced its operations at the mines, the directors consider it exceedingly satisfactory that three consignments of stones should have been already shipped, amounting in the aggregate to 210,000 carats.—*L. and C. Express.*

ODDS AND ENDS.

Take the spots out of white goods by rubbing them with the yolks of eggs, before washing.

Rub windows with a clean cloth wrung out of kerosene oil; rub dry and polish with a clean dry cloth.

Fresh cucumber parings scattered about shelves that are over-run with ants, will, it is said keep them away.

Whole cloves are as effective as camphor—and more agreeable to some—for keeping moths out of clothing.

Dredge a little flour over the top of cake to keep the icing from running.

Purify clothes that have been kept from the air by laying pieces of charcoal (wrapped in paper) in the folds. Try the open air first.

Stoves and ranges should be kept free from soot in all compartments. A clogged hot-air passage will prevent any oven from baking well.

Ink stains on linen can be taken out if stain be first washed in strong salt water and left to stand over night.

New tins should be set over the fire with boiling water in them for several hours before food is put into them.

In bottling catsup or pickles, boil the corks, and while hot you can press them into the bottles, and when cold they are tightly sealed. Use the tin foil from compressed yeast to cover the corks.—*Florida Agriculturist.*

THE JAVA BUDGET.—In the First Chamber of the States-General the reply of the Minister for the Colonies upon the report of the Java Budget has been received, in which the Minister states that the deficit on the years 1886-92 amounts to £2,700,000 while during that period £47,800,000 were spent for public works, and £143,000,000 were received from the coffee cultivation and £6,100,000 from the sugar cultivation, and £4,700,000 from the Banka tin mines. Considering this, reinforcement of the revenue and economy is necessary, but there is no reason to suppose that a satisfactory financial condition would be excluded. The Government has not yet taken a decision as to the time a loan for Java would be issued. With regard to the Ombilin Coalfields the Minister maintains his opinion in favour of working by the State.—*L. & C. Express,* Dec. 25th.

THE CAWNPORE EXPERIMENTAL STATION.—From a summary official notice of the report, we quote as follows:—

The results obtained in some of the green sollar and indigo refuse plots (rabi statements Nos. III and IV) were remarkably good. With what at 16 seeds the average of the plots in statement No. IV, which

were treated with indigo refuse, each gave a net profit of over £60 the acre, rising in one case to £87 the acre. This shows the value of a good wheat crop at present prices. In statement No. III green indigo ploughed in gave a net profit in wheat and straw of £35 an acre. The results obtained by means of the more expensive kinds of manure, such as saltpetre, bone dust, and horse superphosphate, were less striking. The first two cannot be applied at a less cost than £10 the acre, and the third costs £20 the acre. To cover an outlay of £10 an increase of 4 maunds of wheat per acre over the produce of unmanured land is required. In some few of our plots we can show this or a larger increase over a series of years; but this is the exception. The farm is in good order, and has been carefully managed during the year by the Assistant Director and Farm Overseer, Ali Husain. It is frequently visited by zamindars and others, and the ploughs, pumps, sugar mills, and sugar making machines used on it are not unfrequently borrowed by the neighbouring cultivators.

SAFE QUININE.—Levi a Central American physician offers this combination, the administration of which followed by none of the disagreeable buzzing in the head which is the ordinary result of large doses of quinine. Mix and divide into twelve powders 40 grains each of quinine sulphate and peppin, 6 grains powdered capsicum, 12 grains powdered ginger 40 grains sodium bicarbonate. One powder is a dose in neuralgia but in certain conditions the amount may be varied. Vomiting and purging symptoms are averted by the employment of this combination.—*Pharmaceutical Era,* Nov. 15th.

DELIVERIES OF CEYLON TEA IN BRITAIN for 11 months ended November were 49,213,000 lb., and as the deliveries for November were 4,487,000 lb., we suppose we may take 4,500,000 lb. to represent the deliveries for December. If so, the total for the year will be £3,700,000 lb. Remembering the quantities diverted to Australia and other places, this is in very satisfactory proportion to our crop. From Messrs. Geo. White & Co.'s circular we quote as follows:—

Deliveries for November, although half-a-million lb. under those of October, which, however, contained two more working days, compare favourably with November last year, while it is satisfactory to observe that the increased consumption has reduced the Banded Stock from over 17 million lb. on 31st August, to slightly under 15 million lb. on the 30th ult. As an indication that the use of Ceylon Tea is growing on the Continent and elsewhere outside the United Kingdom, it may be noticed that the quantity exported from this country from July 1st to October 31st had risen from 556,000 lb. in 1890 to 829,000 lb. in 1891.

With reference to Mr. J. Astley Cooper's proposed Britinnie Festival, Mr. T. Hudson Bearo writes to the *Morning Post* suggesting that "as the Empire as it now exists is pre-eminently of the Victorian era, June 30th (Ascension Day) should be the Prize Day of the Festival? It would commemorate for ever a most auspicious day in the growth of the Empire—the Accession to the Throne of Queen Victoria. The scholarships might be called the 'British Scholarships.' In the case of those awarded for technical work there should be facilities given, not only for study within University walls, but in the best factories and workshops. On his return to his colony each young man would form a nucleus around which would gather all that was best, and each one would form one of those invisible ties, stronger than any which can be devised by the cunning of lawmakers, which will keep together, for good or for ill, the Anglo-Saxon race." The suggestion merits serious consideration, for it is by close attention to such details as this that the success of the scheme is most likely to be promoted.—*E. Mail.*

THE ESTIMATED CEYLON TEA CROPS
OF 1892 AND 1893; WITH A GLANCE
AHEAD AT A.D. 1900.

A remonstrance has reached us regarding our mention of 95,000,000 of pounds as the possible yield of 1892; and we may at once say that, writing hurriedly, we miscalculated. An estimate of 85,000,000 would be the safer, but we should not be at all surprised to see a crop of 90,000,000 made up, in the shape of 89,000,000 exported and one million consumed locally. We are told that our high figures are calculated to produce a panic, just as we used to be told in the days of advancing coffee crops that our sanguine figures, which generally turned out to be correct, were inimical to the interests of planters. We must say now, as we said then, that our simple duty is to state the truth as closely as the circumstances and conditions within our ken enable us to ascertain it. Mr. John Ferguson, in his able and exhaustive review of the tea trade in the latest issued Directory, wrote: "But too little has hitherto been made of the future production of Ceylon. Even we a year ago blamed a well known Colombo merchant for making known in the City of London his opinion that in four or five years Ceylon would be exporting a hundred million pounds of tea. He is likely to prove a true prophet by present (August 1890) appearances." The writer of the above, who had so closely predicted the crops of 1890 and 1891 at 46 and 68 millions of pounds respectively, and who had adduced data so convincing of the continuance of increases by leaps and bounds for at least the first five years of the present decade, seems to have recoiled from the results of the evidence he had so carefully collected, and he threw forward the realization of the round figure of 100 millions of pounds to 1895. Looking at his own statements of a quarter of a million of acres under tea in 1890, of which a considerable proportion was rapidly coming into full bearing, while much of the old coffee lands were yielding returns far in excess of calculations,—looking also at the actual advances made, year by year (while making allowance for the abnormal flush of 1890), we are forced to the conviction that the era of the round 100 millions must be antedated by two years. We estimate 85 millions of pounds for 1892 and 100 millions for 1893. Not less than 66,000 acres of the quarter million under tea in August 1890 were planted in the period extending from July 1888, and much (most indeed) of this tea will come into full bearing by 1893, while the area of 181,000 acres planted previously to 1888 will have reached full maturity and will be yielding full returns. Mr. John Ferguson's calculation was that the additions to the half million of acres under tea in 1890 were likely to be at the rate of 6,000 acres per annum. These additions we leave out of view, and taking a fair average for the yield of our tea land,—the returns from which are in some cases only 250 lb. per acre, while in a very considerable number of cases they are equal to a yield rising from 500 to 1,000 lb. per acre,—taking a fair average, we say, which we reckon at 400 lb. per acre, the round 100 millions will be exactly made up in 1893. The careful researches of the compiler of the Directory compelled him, after making all possible allowances, to recognize 400 lb. per acre of mature tea as the yield of this hot moist colony. And although his revised estimates for 1890 and 1891 were almost absolutely correct, he was forced to confess: "It will be seen that our estimates of a year ago

for 1890 and 1891 were far below the mark; the present year has, in fact, in crop bearing exceeded all expectations. It has shown that tea on old coffee land, after six or seven years, yields far more leaf than was anticipated." He accordingly revised his estimate to 63 millions for 1891, which are almost exactly the figures in the Chamber of Commerce return. With commendable caution he gave 80 millions for 1892 and 90 millions for 1893. Our estimates, therefore, of 85 millions for 1892 and the round 100 millions for 1893, are not, we submit, considering all the circumstances, extravagant. Of course, our estimates might be somewhat affected by the extensive or universal adoption of finer plucking than now prevails; but supposing there is no material change in this respect let us see what inferences we are justified in deducing for the future from the experience of the immediate past. We have shown that the rate of increase in our crops is not at all likely to diminish up to 1893. What have the rates been since 1881 when our exports (we take the customs figures,) reached 2,392,000 lb.? Next year the export very nearly doubled, the figures being 4,372,000. This was an increase of very nearly 50 per cent. The increase to 7,840,000 lb. in 1876 was not so great. Then came an increase nearly at the same rate, the figures for 1887 being 13,834,000 lb. Then came a diminished rate of increase, the figures for 1888 being 23,820,000 lb, an excess of 10 millions over the previous year. A somewhat larger rate of increase marked 1889, the figures being 34,345,000, an increase of 10½ millions. There was a still larger advance in 1890, to 45,799,000 lb, an increase of nearly 11½ millions. Finally the figures rose to 67,000,000 in 1891, an increase over the previous year of no less than 19 millions. Conceding that this latter case is exceptional, and taking 15 millions as the rate of increase for this year and the next, respectively, we get total crops

For 1892 82,000,000 lb
,, 1893 97,000,000 ,,

An annual increase of 15 millions on the much higher figures is so much lower a percentage than previous increases of 10 and 11 millions on the smaller quantities of previous years, that we suspect the increases will really be greater and fully make up our revised estimates of 85 millions for the present year and 100 millions for 1893. If readers admit, as we think they must, that our estimates are founded on indisputable evidence, connected with specially favourable conditions of soil and climate which are as likely to be operative in the immediate future as they have been in the immediate past, the strongest possible case will be made out not only for continuing but for indefinitely extending the efforts made to open new markets for our teas.

We have shown reasons for expecting a largely increased production this year and the next in the fact of the whole 250,000 acres under tea in August 1890 attaining maturity and full or nearly full bearing in the course of the two years. In years subsequent to 1893, we have reason to look for a considerably diminished rate of increase say to about 7 millions per annum, which would make the export of Ceylon tea as nearly as possible 150 millions in the last year of this nineteenth century. So much will depend on continued and expanded demand at remunerative prices. Such conditions granted, we believe our figures represent the very minima of results.—If our reasoning is wrong let the fallacies be pointed out, but there is no use shutting our eyes to the inevitable effects on tea of our specially forcing climate and fairly fertile soil. If our anticipations are fulfilled, and a crop of 100

millions of pounds of tea is harvested in Ceylon, in 1893, the result will, we believe, be unexampled even in the annals of tropical agriculture. In 1872, not a pound of tea entered into the exports of Ceylon. In the twenty years succeeding 1872 and ending with 1893 the enterprise will have made yearly increasing additions to the commerce of the colony rising from a few pounds valued at a few rupees to 100 millions of pounds, of a local value, we trust, of not much under 50 millions of rupees. That will not be much behind the culminating period in the history of the coffee enterprise. While that enterprise may revive, we have every reason to hope, from the experience already gained, in the comparative permanency of the tea enterprise. In almost complete exemption from blights, tea culture in Ceylon has an advantage of great magnitude over the similar pursuit in northern India. In quality too, judging from demand, our tea stands high. Stood high, at any rate, until the overwhelming production of last year; and we must not close without adding to our arguments in favour of opening new markets for our chief product an earnest appeal to planters to pay such attention to quality as will not only retrieve the reputation of Ceylon tea but place it on a higher level in public favour than ever, so that it may hold existing markets and capture new by its superiority to all competitors.

CEYLON TEA CULTURE, &c.

On this subject Mr. J. C. White* writes as follows:—When it is known that the tea plant is indigenous to Ceylon, it cannot be a matter of wonder that the cultivated plant should produce such a splendid article of domestic consumption as the tea now imported from that island, some rare samples of which are said to have realised lately in London seventy guineas a pound. The natives had small plantations of coffee in the early days when the Portuguese took possession of the island in A.D. 1505. The Dutch, who subsequently expelled the Portuguese, landed there A.D. 1602, taking possession of the coast country, the Candians retaining the interior under the rule of a native king residing at Candy, the capital. The British turned the Dutch out in 1796, and soon after, in 1802, the Candians were subdued, and the whole island became a British colony, the chief exports of which were cinnamon and other spices, coffee, coir, copra, pearls, and precious stones. The tea plant was unknown to the Portuguese or Dutch. Neither the Portuguese nor the Dutch had coffee plantations; it was grown by the Cingaleses, who cultivated it as boundary fences to their properties, as may be seen to this day in the pretty homesteads hid away in the grove of coconut trees between Colombo and Point de Galle, a distance of about 70 miles. Ceylon being for a long time under military government, there were but few capitalists, and they belonged to the military and Civil Service, and it was upwards of 20 years after British occupancy that coffee planting was started as a commercial enterprise, for in 1825 there were only two plantations on the island—one at Paradenia, on the Maha Villa Ganga River, near Kandy, the property of the Governor Sir Edward Barnes; and the other at Gampola, about eight miles south, the property of Colonel Bird, where I first acquired my colonial experience in coffee growing. The business was carried on very

* This is the old gentleman, contemporary and playmate of Sir Charles Peter Layard, who, some time ago, sent us an interesting account of himself and his experiences in Ceylon and New Zealand. We need scarcely say that tea is not indigenous to Ceylon, and that coffee was unknown in the island until introduced and cultivated by the Dutch. Kandy, too, did not become British until 181.—Ed. T. d.

extensively for about half a century after that, and the product being equal to the best Mocha coffee, that article became one of the principal exports of Ceylon. The leaf disease (so called) made its appearance on the island, and decimated all the large plantations, and the attention of planters was directed to the cultivation of the tea plant, which it appears had been growing wild in the jungles of Ceylon, and for a period of nearly 300 years after European occupancy had, like the modest violet, been shedding its fragrance unnoticed in the desert air.

I have now before me a very interesting history of the island of Ceylon, published in 1805, by Captain Robert Percival, of the 18th Royal Irish Regiment, who was present at the capture of the island from the Dutch in 1796, giving an account of the natural productions. I herewith quote his words:—"But it is not sugar alone that Ceylon seems destined to afford to the general use of the Western world; the tea plant has also been discovered native in the forests of the island. It grows spontaneously in the neighbourhood of Trincomalee and other northern parts of Ceylon. General Champagné informed me that the soldiers of the garrison frequently use it. They cut the branches and twigs and hang them in the sun to dry; they then take off the leaves and put them into a vessel or kettle to boil to extract the juice, which has all the properties of that of the China tea leaf. Several of my friends have assured me that the tea was looked upon as far from being bad, considering the little preparation it underwent. The soldiers of the 80th Regiment made use of it in this manner on being informed of its virtues and quality by the 72nd Regiment, whom they relieved. Many preferred this tea to coffee."

Neither the Government nor the public seem to have taken notice of this fact until after the coffee exportation became a partial failure. I believe it is generally admitted that the Ceylon tea is likely to supersede the use of the China article, as also of the Indian or Assam. The qualities are not sufficiently known to be appreciated. A much smaller quantity is requisite for a decoction, and the great secret of making it is not to let the teapot stand too long before use. Making tea in the usual way by infusing the leaves too long, the extract of the leaf is too strong and the flavour disagreeable to some tea-drinkers. I have heard it as a fact that made as I have described the leaves can be drained or laid aside and made into a second brew. I know the Chinese are in the habit of saving and drying the leaves of the tea they use to increase the quantity of the article they sell, and it is not at all unlikely that they will do the same with the Ceylon tea, thus adding flavour as well.

I do not advocate the use of Ceylon tea because it is the product of my native country, but I like it much better when properly made than the other imported articles, and I know it will go further, and consequently much cheaper; and I presume economy is, or should be, the order of the day in domestic circles.—*Auckland Weekly News*, Nov. 21st.

WASHING CACAO.

SANTA CRUZ, 10th February, 1891.

Dear Sir,—At the last meeting of the Central Agricultural Board, I had the honor to lay before the Board, *vis a vis*, the result of my experiments with regard to the advisability or not of washing cacao Ceylon fashion and to the loss in weight which such operation involves. I have been requested by the members then present to put my remarks in writing so that they may be published in the *Agricultural Record*, and I accordingly send you the following notes which, if having no other merit, have the advantage of being based on facts and figures indisputable.

My attention has been called, in 1889, to the Ceylon method of preparing cacao by a letter from Mr. Frostee published in the *Trinidad Chronicle* some

years back in which he saw no reason why the very best of Trinidad cacao should not be better than it is now, and as Ceylon prices averaged something between 20/ and 30/ over Trinidad cacao I decided to give the matter a serious trial in hopes of obtaining at least 10/ more than I did then.

Accordingly on the 24th of October, 1889, I wrote to England for a sample of Ceylon cacao to go by, and in the meantime I put up on my Estate the necessary requirements for washing cacao: pipes 1½ diameter and 650 feet long to lead the water to a concrete trough 32 ft. x 1 ft. 1 x 3 ft.

In answer to my letter, instead of the desired sample which could not be obtained at the time, I got a report from Messrs. Wilson, Smithott & Co., Brokers, that it was not advisable to imitate Ceylon cacao because the principal value of that class of cacao resided in its pale cinnamon break which, whether due to the soil or to the different variety of cacao, Trinidad planters could not imitate. I thought, however, that having once begun I could not give up this matter without fighting it through and I again insisted for the sample to guide me.

In the interval I had prepared a small quantity of washed cacao for the San Fernando Exhibition and the Hon'ble W. Gordon, one of the Judges who gave that sample a 1st prize, having informed me that it was similar in external colour to the best Ceylon cacao he had seen in England and that the beans were twice the size of Ceylon beans, I immediately prepared a shipment of 13 bags for the English market.

This shipment was effected on the 14th March, 1890, and a few days after I prepared another lot of 12 bags which I sent to America so as to test both markets.

I had not yet received the sample of Ceylon cacao which I was anxiously expecting when by a letter dated 19th March, 1890, I was informed of the cause of the delay which had thus taken place. The following extract of the letter will speak for itself:

"The sample of Ceylon cacao which we addressed to you by Parcel Post last mail came back a day or two afterwards with the intimation that cacao was prohibited to be imported into Trinidad! We are having another try by this mail, by letter post this time and if you do not receive it you will know it has again come to grief somewhere—in Port-of-Spain probably."

I am glad to say that the Post Office authorities here could make a better distinction between the spirit of the law and the letter of the law than the authorities at home and I got my much desired sample at last.

I tried all I could to imitate the internal break and I approached it somewhat by sweating the cacao 12 to 14 days; but then the external appearance became darker and this could not be sacrificed only to approach faintly the internal appearance. My friend, Mr. C. de Verteuil, also received samples of Ceylon cacao and had them analysed and compared with his cacao. Analysis shewed no difference between the two except a very small percentage of theobromine more in Trinidad cacao.

In reference to the first shipment to England I received a letter dated 24th April, 1890, of which the following is an extract:—

"Now as regards the 13 bags of Ceylon cacao the appearance is simply splendid and we most heartily congratulate you on the result; but after all the one point to be considered is—Will it pay? One of our largest buyers of Ceylon cacao saw the sample yesterday and was loud in his praises of it but summed it all up in those words:—"Yes, I dare say you'll get a few shillings extra for it, but try all you can and you'll never get the Ceylon colour inside." However, this is a pure experiment and a very interesting one too, and the great object is to establish, if possible, a high price for this little parcel to act as a kind of precedent for future shipments. By dint of careful manipulation our Brokers hope to take advantage of the fact that certain buyers of Ceylon cacao are now being frightened away by the abnormally high price now ruling, and if some of these can be tempted to give yours a trial at some price

between 80/ and 90/ as against 100/ to 110/ for Ceylon, it will be an important step in the right direction. You must however bear in mind that the new cure to some extent reduces the strength of flavour while it fails to give that delicate pale colour inside which is the great attraction in Ceylon cacao. In addition to this the Ceylon production is very small and the demand for it, though relatively large, is actually also very small; consequently if it were possible for all Trinidad cacao to be prepared exactly like Ceylon cacao the difference in price would probably no longer exist, as the supply would then far exceed the demand."

Notwithstanding this flattering opinion the cacao was put up at auction and only elicited a bid of 70/ as against 68/ ruling at the time for my ordinary cacao. It was withheld however by my instructions and later on, after great pains and tact by the part of my agents was disposed of at 85/. I was advised at the same time that this sale must be regarded purely as an experiment and not as having established a market value.

In America the second lot met with a ready sale at 17½ cents per lb. and having received the account sales of this lot before that of the 13 bags to England, I continued to ship to America a few parcels of 5 and 7 bags respectively which fetched 16 to 16½ cents. From there also I was informed that if any great quantity of this cacao was shipped at a time the price would fall; and so it turned out, for others shipped to America also and the price fell to 14½.

The crop having come to an end I could not continue to ship until October this year, when I wrote home to say that I was going to prepare all my crop Ceylon fashion and asking for an opinion on the matter. But the price of ordinary cacao having gone up 2/, I thought it was wise to send a trial shipment of both qualities at the same time before running the risk of losing the advantage of a rising market for the ordinary kind. Consequently I prepared 17 bags ordinary and 10 bags Ceylon fashion which were shipped by the same boat and put up to auction at the same time. The former was sold at 65/ and the latter at 68/; but on account of the difference in weight the former yielded £5 17 3 gross and the latter £5 9 6 gross, that is 7.6 less notwithstanding the difference in price. I was advised therefore that "taking into account the great loss in weight in preparing your cacao Ceylon fashion it seems to us that the small extra price you will obtain for it will not compensate you."

It is needless to say that I am following that advice, the more so that my next lot of ordinary cacao was sold at 68/, the same price which the Ceylon process had fetched.

With regard to the loss in weight as from one method to the other, the question was practically settled by Mr. C. de Verteuil, of Maracass Bay, who from the same sweating-box weighed a certain quantity of cured cacao and prepared that lot, the ordinary way of dancing, rubbing and sun-drying, and weighed again an equal quantity which was immediately washed and sun-dried. The difference was 14 per cent. less for the washed sample when dried.

I was then present when this test was taken and did not renew it. But in course of practice I can again say that the same number of baskets measured in the field which gave me a bag of ordinary cacao also gave me a bag of Ceylon prepared cacao, with this difference that the Ceylon bags weighed 12 to 14 per cent. less than the others. Practically therefore I may state that the loss of weight in washing is 14 per cent.

The actual results, so far as I am concerned shew that the English market is not ready to take up our cacao, washed, at a much higher price than the ordinary kind, whilst in America only small quantities at a time can be depended upon to fetch good prices.

But does that settle the matter once and for all against washed cacao? I hope I may not be looked upon as a utopist if I venture to submit that, notwithstanding this initial failure, to wash cacao is the only rational way of preparing that article for the following reasons:—

1st—It is indisputable that the cacao shell with

its coating of dried and decomposed muckage, and in some cases with an adjunct of red earth or red ochre, cannot be a wholesome article of food, and I believe large manufacturers have to remove that shell before manufacturing chocolate. The loss of weight to be met with in washed cacao is also therefore to be taken into account by the manufacturer, plus the cost and labour of removing these impurities.

2nd—Artificial drying has to be resorted to sooner or later, and already I may say that Mr. C. de Verteuil has successfully initiated such a means of drying cacao in bad weather.

It is evident that the beans when washed will not only dry quicker and save fuel but also they will not require to be hand-rubbed and danced and thus save labour.

Why then will manufacturers not pay higher for washed cacao?—I suppose the natural tendency of manufacturers to keep down the price of the raw product is responsible for that. But time would soon convince them that it would be to their advantage to buy a clean article and the public also would prefer to purchase chocolate manufactured undoubtedly from a clean and pure article.

Why then cease to prepare my cacao Ceylon fashion?—I am but an individual and can ill-afford to lose money for any length of time; but a company, with very little capital, which would start a central factory in Port-of-Spain, for instance, where abundance of water can be had, where by rail they could receive the raw product from small and large proprietors, where also they could put up cheap artificial drying houses, would be the right thing to put the washed cacao on the markets of the world and to have it in time appreciated as it should be.

Not only such a company would make money but small proprietors and some large ones, I venture to predict, would have a ready sale for their product especially in bad weather, and the name of Trinidad cacao would again stand foremost in the markets of the world.—I beg to remain Dear Sir, Yours very truly,

Eugene Lange, Jr.

—Trinidad Agricultural Record.

THE CASTOR OIL PLANT.—No sort of bird, beast or creeping thing will, says an American paper, touch a castor oil plant. It seems to be a rank poison to all the animal world. Even a goat will starve before biting off a leaf, and sniff at it and turn up his upper lip as though it had the most detestable odour on the face of the earth. Army worms and locusts will pass by it, though they may eat every other green thing in sight, and there is no surer way to drive moles from a lawn than to plant a few castor beans here and there. Even the tobacco worm will refuse to feed on its leaves. There is hardly another instance in natural history of a plant being so universally detested by the animal world. And yet we know the Eria silkworm of Assam feeds freely and thrives well on the leaves of this plant.—*Indian Agriculturist*. [Castor oil plants grown on a large scale in Ceylon as a supposed protective of Liberian coffee, if we remember aright, had their leaves all eaten off by an insect. There is actually an insect which does not revolt even at tobacco!—*Ed. T. A.*]

A CORRESPONDENT points attention to what tea will do at Darjeeling, or rather to what it has done in an instance the Dooterish Tea Estate, which was sold by public auction during the crisis of 1866-67 for Rs20,000, and is now worth 13 lakhs or more. It was sold in the usual manner by Mackenzie, Lyall and Co., and knocked down to Colonel A. Myers, of the Madras Fusiliers, who was joined as a half share by the late Dr. J. P. Brougham, of Calcutta. For more than 20 years past the property has yielded a princely income to both partners; and since Dr. Brougham's death Colonel Myers being desirous of acquiring the other half-share

is understood to have made the doctor's heirs *bona-fide* cash offer of nine lakhs of rupees for it, which has been refused! Surely, if this is not quite as good as a gold mine, it must be pretty nearly so. And there are other properties in the neighbourhood which changed hands to similarly low figures during the same crisis which are known to have done and to be doing almost as well as the Moonda Kotes Garden for instance, which along with more half-a-dozen others was taken over by the Land Mortgage Bank for some Rs50,000 after the original owners had spent about 3½ lakhs upon it. It is a pity it is so difficult for the public to ascertain reliable particulars as to the working of the Darjeeling tea gardens. There used to be an *Indian Tea Gazette*, in which one would naturally expect to find information of this sort, but I understand it is now defunct.—*Indian Agriculturist*.

The sedimentary deposit taken out of ponds is largely composed of dead leaves. This material forms a very useful dressing if spread alone over a bare or thin part of a field, but it would be more desirable to have it mixed with lime before application. The lime hastens the decomposition of the organic matter in the leaves and other debris of vegetable forms, and materially adds to the usefulness of the dressing. The stuff taken from the pond may also be profitably used in covering dung heaps, as it will serve not only to waterproof the dung heap, but also to absorb any ammonia that might otherwise escape from the decomposing dung.—*Indian Agriculturist*. [A hint this for utilizing the offensive but fertile dredgings from the Colombo Lake.—*Ed. T. A.*]

CEYLON TEA IN LONDON.—Messrs. Gow, Wilson & Starton write to us by this mail:—

"The market for Ceylon tea as you will see has somewhat advanced from the lowest point, and as competition is general and a good all round demand prevails, the prospects are somewhat more encouraging than they were two or three weeks back. It must not however be forgotten that large quantities of tea will shortly be arriving from the Island, and these if forced on the market too quickly, may somewhat overtax it, although we sincerely hope that this will not prove to be the case, as there is generally a considerable business transacted in the first few months of the year. With kind regards, and wishing you the compliments of the season; and wishing Ceylon Tea Planters generally a Happy and Prosperous New Year with better prices than we have recently seen."

THE COMMERCIAL VALUE OF EGYPTIAN PETROLEUM.—We have heard a good deal from time to time about Egyptian petroleum, and of the possibility of the mineral oil which is found at Geusah on the shores of the Red Sea, becoming an important factor in the oil trade of the future. That being so, it will be interesting to learn something concerning the character of this oil. The illuminating power was tested in Elster's photometer; the burning oil gave a light of 98 standard candles (German). The weight of oil burnt per hour was 31 grams. When exposed to the air the oil rapidly developed an unpleasant odour. Messrs. Kast and Kunkler are of opinion that Egyptian petroleum is not suitable for the manufacture of illuminating oils, but is an excellent material for the preparation of lubricating oils.—*Chemical Trade Journal*.

NEW ADULTERANTS.—M. Callard announces his discovery of two more new adulterants of saffron, viz. fine shreds of onions, dried and coloured artificially, and also the powder of "sweet cayenne" or paprika, made adherent to the style by some agglutinating agent, which he believes to be honey. This second adulterant he finds present in as high a proportion as 60 or 70 per cent. or more.—*Chemical Trade Journal*.

GARDEN NOTES.

(From the Proceedings of the Agri-Horticultural Society of Madras.)

ARAUCARIAS.—A number of young *Araucarias* were planted out, in October, on each side of the main walk from the entrance gate, and with the exception of three specimens of *A. bidwillii*, look very healthy. Attempts have been made, on former occasions, to grow *A. bidwillii*, in pots and in the open ground, but have failed. Mr. Whiteside informed the Committee that he had made several attempts to grow *Araucaria bidwillii* in his garden, and that, when it was removed from the pots in which it was thriving and planted in the open ground, it invariably died in a few weeks. On the other hand, *Araucaria excelsa* did very well in the open.

BAMBOOS.—Mr. J. S. Gamble, Conservator of Forests, recently identified the following species of Bamboo, which are growing in the Society's Gardens:—

Bambusa arundinacea.—India and Burmah.

" *nana*.—China.

" *rubra* var. *aurca*.—China.

Cephalostachyum flarescens.—Burmah.

Dendrocalamus humiltoii.—Sikkim, Bhitam, Assam.

" *giganteus*.—Penang.

" *strictus*.—India and Burmah.

Ochlandra travancorica.—Tinnevely.

Trinostachyum rightii.—W. hills of India.

The plants of *Dendrocalamus humiltoii* and *Trinostachyum rightii* were raised from seed received from Calcutta and Trivandrum respectively. The giant Bamboo, *Dendrocalamus giganteus*, has been recently introduced into the Public Gardens at Trivandrum (Travancore) from Ceylon, and is flourishing in the moist climate.

Besha travancorica.—Seedlings of *B. travancorica* (Elephant grass) were received from Mr. Rhodes Morgan in 1886. One of these is now 10½ feet high and 5 feet broad, and is much more effective as an ornamental plant than the ordinary Bamboo.

Dillenia spectiosa has flowered recently for the first time in the Gardens. The plant is 16 feet high.

VICTORIA REGIA.—The Honorary Secretary reported that, while visiting Ceylon recently, he took over with him, at the request of His Excellency Sir A. Hamilton Gordon, some young plants of *Victoria regia*, for the new tank in the Fort Gardens, Colombo. Two of those plants were, at the date of his departure from Ceylon, two months later, growing rapidly in the tank, which is supplied with running water, and looked perfectly healthy. Some seeds of *Victoria regia*, which had been sent to Ceylon earlier in the year, germinated a short time before his arrival on the Island.

The *Victoria regia* in the Society's Gardens, which was removed last year from the tank near the Palm House to the tank in the nursery, is in a very flourishing condition. In December, out of sixteen leaves, six measured 7 feet 8 inches in diameter.

Sir Charles Lawson observed that the leaves of the *Victoria regia* near the Palm-House seem to have diminished in size under the influence of the slightly brackish water, with which the tank is supplied. The tank in the Nursery Garden is supplied with rain water, and the greater size of the leaves, as compared with those in the other garden, is noticeable.

INSECT PESTS.—Mr. Thurston exhibited specimens of the following species from the Madras Presidency:—

1. *Stenotus gremius*, one of the *Hesperidae*, which is reported to do great damage to the paddy plants in the Balasore District, Bengal, though Mr. L. do Nieville is inclined to doubt the fact.

2. *Lampides cypis*, one of the *Lycenidae*, which is said to do so much damage to the Cardamoms in Ceylon that from 5 to 10 per cent. of the fruit capsules are perforated by the insect. Mr. Owen estimates the damage done by it to be sometimes as much as 80 to 90 per cent. to young plantations.

3. *Papilio erithonius*, one of the *Papilionidae*, which has been reported by Mr. Cameron of Bangalore to attack lemon trees. The insect also does much damage to young budded oranges.

4. *Cryptorhynchus mangifera*, the Mango Weevil.

5. Larvæ of a noctual moth *Achæa melicerte*, which is said to attack Castor-oil plants, and reported by the Collector of Ganjam to attack sugarcane, paddy, and brinjals.

6. *Nezara viridula*, the green Bug, which is reported by Mr. Cameron as occurring on potato halm in Bangalore.

Much information on these and other pests will be found in the Indian Museum 'Notes on Indian Insect Pests.' The Committee considered that it is very advisable to keep a collection of Insect Pests which are injurious to plants and trees for inspection in the Society's office. The Honorary Secretary will be glad to receive specimens accompanied by notes thereon.

BRANCHING PALMS.—"In the *Journal of the Linnean Society*, 1871, Vol. XI., Dr. Shortt published an account, with illustrations, of some branched Palms from Southern India, the species mentioned being the Palmyra Palm or Borassus, and the Cocos. Our present illustration (fig. 40) is taken from a photo kindly sent to us by Mr. T. H. Storey, the Superintendent of the Sujan Niwas Gardens, Oodeypore, Rajpootana. The species represented is the Wild Date, *Phoenix silvestris*. Mr. Storey tells us the occurrence is quite rare, he having seen hundreds of miles of Date trees, but only this one group of branched Palms growing in a jungle, about 30 miles from Oodeypore. Mr. Storey continues: "There is a large beetle (identified for us by Professor Westwood, as *Scarabæus (Oryctes) rhinoceros*) which is very destructive to the Palm family. It bores a hole right through the centre of the tree, and cuts all the leaves off. I think this beetle may be the cause of the Date Palm's branching. I have in the garden one tree which has been attacked, and it is now throwing out a side-shoot." We have no doubt Mr. Storey's conjecture is correct, and that the branching is an attempt to remedy the evil consequences of the injury inflicted by the insect."—*Gardener's Chronicle*, September 7, 1889.

The Committee observed that in some instances, the parts of the flower, instead of attaining the normal condition, assume the form of leaves. Some years ago Dr. Shortt sent to Surgeon-General Bidie an example of this in a Coconut, which has, unfortunately, been lost. A good example of a branching Palmyra Palm is, or was a few years ago, growing in the Assistant Collector's bungalow at Rannad.

Mr. Whiteside informed the Committee that, some years ago, he found, in the Polar tank of the N. Arcot district, a Palmyra tree which had three branches, the stem of the tree being encircled by the roots of a healthy young Banyan tree, the seed of which had, doubtless, been deposited by a bird. He had the tree photographed, but the plate was unfortunately broken when on its way to Madras to be developed.

MANGO WEEVIL.—(*Cryptorhynchus mangifera*). In a note on a communication from the curator of the Perak Museum on the subject of this pest, 'Nature' observes (August 22, 1889) that "it is believed that it lays its eggs in the flower or very young fruit, for in the ripe fruit there is no external mark to show where it gained an entrance, and it is not until the perfect insect eats its way out of the mango that it is possible to tell whether any particular fruit is sound or diseased. Some varieties of the mango enjoy complete immunity from the attacks of this insect, and it has been noticed that even particular trees of varieties which are not so favoured always escape. This fact seems to hold out a hope that, by careful selection, good varieties of the fruit could be raised, which would not be subject to the attacks of this destructive pest. The character which renders the fruit unsuitable for the weevil is, and probably always will remain unknown, as our senses may not be keen enough to detect the particular taste or smell which prevents the female from laying her eggs in the fruit of the naturally protected trees."

[As a rule mangoes grown in Ceylon seem to be free from insects. We can only remember some grown at Jaffna being infested.—Ed. T.A.]

THE CHEMISTRY AND COMMERCIAL POSSIBILITIES OF WATTLE GUM.

BY J. H. MAIDEN, F.L.S., F.C.S.,

Curator of the Technological Museum, of New South
Wales.

The subject acquires additional interest on account of the short supply of good gum arabic, and the categorical statement which has been more than once made that Australia might meet the demand. Although a common product, seen and known by everyone in the Colonies, it is singular that wattle gum has not hitherto formed the subject of systematic research. In the following pages I have treated the subject both from a botanical and chemical point of view, and have, I believe, included all published references to the subject. My researches and observations, conducted with exceptional facilities for thoroughly sifting the subject, have caused me to arrive at the conclusion that Europe and America must not look to Australia for any quantity of high class gum.

Wattle gum is the produce of various Australian species of *Acacia*, a genus which is very largely developed in that continent, comprising about 320 species, besides a large number of well marked varieties.

Gum has, however, only been recorded from comparatively few species, as by far the great majority have no local names, and where it has been collected at all it has usually been styled "wattle gum." The present paper includes all species known to the author as having yielded gum in Australia; several of the gums are now recorded or described for the first time. The specimens described are in the Technological Museum.

Speaking of Wattle gums in general, Bontley and Trimen, 'Medicinal Plants,' say, "It is found commonly in large tears or masses of a dark yellow or reddish-brown colour. This gum, which has a transparent appearance, being nearly free from cracks or fissures, is said to be readily soluble in water, and to form a very adhesive mucilage. It is frequently contaminated with pieces of the astringent barks of the trees from which it is obtained, hence its solution, unless carefully prepared, will frequently contain some tannic acid." This is an objectionable constituent, as it affects the mordants in calico printing.

"Best selected Turkey gum" is the ideal gum of the group to which Wattle gum belongs, and if judging were to be by points, it would take the highest place as regards absence of colour, freedom from accidental impurities, ready solubility, and adhesiveness of its mucilage. The Australian gums seen by the author for the most part fall far behind this high standard, although specimens of those from *A. homalophylla*, *A. pendula*, *A. sentis*, and *Flindersia maculosa* compare with it very favourably. As far as his experiments go, those samples obtained from the interior (comparable in its aridity to the Soudan and other noted gum-producing countries), are completely soluble in water, and make good mucilages, while those obtained east of the Dividing Range, *i.e.*, in well watered districts, in which vegetation is comparatively luxuriant, are more or less insoluble, portions, at least, merely swelling up in water, like cherry gum. In other words (speaking of the Eastern colonies, in the absence of detailed knowledge of the western one), the eastern Wattle gums contain metarabin, while the interior ones do not. And when it is borne in mind that the yield of gum in the interior is insignificant

* Perhaps this statement has arisen from the following:—"Generally speaking, the Victorian acacia gums are somewhat less soluble than the gum arabic of commerce, but, on the other hand, they appear to yield a more adhesive mucilage, which is less liable to splinter and crack when dry" (*Report on Indig. Veget. Subst.*, Victorian Exhibition, 1861.) This statement gives an exaggerated idea of the value of Victorian gums, and of Australian ones generally.

as compared with that of the coast country, it becomes apparent how hazardous is any generalization that Australian gums are readily soluble in water.

I do not think there is much commercial future before Australian gum, on account of the high price of labour, except in the few localities where gum is very abundant and of high quality, and because the natural gum-yielding trees have been largely destroyed for their tan-bark and for firewood.

Wattle gum oxides chiefly during the summer season from fissures and accidental injuries to the bark. After careful observation, I have formed the opinion that, as a very general rule, it is a pathological product. I came to this conclusion long before I was aware of Trevel's observations, that *Acacia* and the *Rosaceæ* yield their gums most abundantly when sickly, and in an abnormal state caused by a fulness of sap in the young tissues.

Wattle gum of various species is largely eaten by the blacks, and, by those of the interior at least, especially with fish. This fact is well-known in the Colonies, and I give a few quotations from explorers on the subject. Following is Captain Sturt's account of the occurrence and use of Wattle gum by some natives of Central Australia:—"Among other things we found a number of bark troughs filled with the gum of the mimosa, and vast quantities of gum made into cakes upon the ground. From this it would appear that those unfortunate creatures were reduced to the last extremity, and being unable to procure any other nourishment, had been obliged to collect this mucilaginous food" ('Two Expeditions into the Interior of South Australia,' *etc.*, 1828-31, i., 118). Captain Sturt was not then aware that the natives by no means look upon Wattle gum as starvation food.

Captain J. Lort Stokes ('Discoveries in Australia') gives "Minnung" as the name of a Western Australian *Acacia* whose gum is "very abundant," and eaten by the natives.

Captain (now Sir George) Grey gives the following account of the use of Wattle gum (? *A. microbotryta*) by the natives of Western Australia:—

"The gum of the mimosa is a favourite article of food amongst the natives. . . . *Kwonnat* is the kind of gum which most abounds, and is considered the nicest article of food. It is a species of gum tragacanth (*sic*). In the summer months the *Acacias*, growing in swampy plains, are literally loaded with this gum, and the natives assemble in numbers to partake of this favourite esculent. As but few places afford a sufficient supply of food to support a large assemblage of persons, these *Kwonnat* grounds are generally the spots at which their annual barter-meetings are held, and during these fun, frolic and quarrelling of every description prevail." ('Journal of Two Expeditions,' *etc.*, ii., 260, 294). Captain Grey also makes the interesting statement (p. 298) that some of these *Kwonnat* grounds appear to be visited by numerous families by acknowledged right at the period when the gum is in season, although not allowed there at any other time. This hereditary ownership is very rare amongst the aboriginals, although it is exercised in the well-known instance of the *Leucocaria Bidwelli*, of Queensland.

Small boys eat the more insoluble gums, particularly when made into a jelly and sweetened (see *A. decurrens*).

Wattle gum is considered useful in diarrhoea (in such cases a little astringency would of course be an advantage rather than a drawback) and piles. It is also said to be employed in veterinary practice in the country for wounds and raw shoulders in horses.

I have been shown a statement by "a good practical man" that Wattle gum dissolved in benzole "makes an excellent carriage varnish." Perhaps here will be a convenient opportunity to point out that Wattle gum is quite insoluble in that liquid, to say nothing of the ridiculous suggestion to use a true gum for a varnish, and to protest against the reckless statements which are made in regard to our little known raw products.

It would appear that some species, which in their

native habitats yield gums more or less insoluble, produce more soluble products when grown in some other countries. The question is a wide one, and well worthy of being followed up, for it would be of the highest commercial importance if it could be shown that free-yielders of inferior metameric gum would in other soil and climate develop a tendency to the formation of arabic gum (see *A. dealbata*, *A. decurrens*).

Some notes by Dr. Hopff on an Australian Wattle gum as compared with gum arabic will be found in *Pharm. Jour.*, vii., 588. The experiments have no conclusiveness, and the source of the Wattle gum is not given, for it was probably unobtainable.

I have divided the Wattle gums experimented upon into three provisional groups. I could make sagacious guesses as to the groups into which many other Wattle gums are likely to fall, but prefer to confine myself to the record of facts. The classification of the future will probably be into arabin and metarabin groups, in which case my groups II. and III. will simply require to be united. The samples chosen for analysis were picked ones in all cases.

GROUP I. (ARABIAN GROUP.)

Acacia homalophylla.

Acacia pendula.

Acacia sentis.

They are readily and entirely soluble in cold water, like Turkey gum arabic, for which they form an excellent substitute. Arabin is their characteristic and main constituent. Following are analyses:—

Arabin. Metarabin. Moisture. Ash. Total.

A. homalophylla... 79.84 — 16.83 2.86 99.53

A. pendula var.

glabrata .. 79.5 — 17.51 2.39 99.40

A. sentis ... 76.97 — 17.88 4.59 99.44

Acacia homalophylla, A. Cunn.; 'B. Fl.' ii., 383.

The common "gidgee," found in Northern America,

Victoria, and New South Wales. This tree yields gum copiously throughout the summer season.

My sample outwardly resembles, in a striking manner, common pine resin or "rosin." Its fracture is conchoidal and very lustrous. From its resemblance to "rosin," its colour is a drawback, but it is remarkably bright and clean, and as it is so freely soluble, and so adhesive, it would well pay to export, could it be obtained in sufficiently large quantities. It dissolves entirely in cold water, forming a very pale yellow, almost perfectly transparent liquid.

Mr. Edward Palmer ('Proc. Roy. Soc., New South Wales,' 1833, 94), states that gum of this species is eaten by the blacks of Northern Queensland, but there is apparently some confusion in the locality, as I am not aware that this species extends to that colony.

Acacia pendula, A. Cunn., var. *glabrata*, F. v. M. Perhaps co-extensive in geographical distribution with the normal species. *A. "Yarran"*. Sample obtained from between the Lachlan and Darling Rivers, New South Wales.

There is a marked difference between the new and the old gum of this sample. The new gum is in rounded pieces, and very similar in appearance and usual size to Senegal gum, and Aden gum arabic. The gum which remains long on the trees becomes filled with minute fractures which cross each other nearly at right angles. The fissures which radiate from the centre of a lump cause the lump to break into sub-triangular or conical pieces, but as distintegration proceeds, these pieces are broken down into small angular fragments. It is worthy of notice that the colour of the lumps varies in depth from the centre outwards, and the bands of colour are usually fairly well defined. The difference in colour is dependent upon the extent to which the fissuring has proceeded. As fissuring (the result of weathering) is most evident on the outside of a lump, and as the process of repeated reflection of light makes the part affected lighter in colour, though more opaque, the colour of the gum increases in depth as the central portions of a lump are reached. A common tint for the outside (or basal portion) of a conical piece is amber, that of the inside (or apical portion)

"rosin brown." I have described these appearances at some length, because they are commonly seen in the "dry country" gums.

Like other Wattle gums, this would require selecting for the market, but some portions are of very high class. It dissolves entirely in cold water, forming a perfectly clear solution, almost colourless, with the exception of a brownish tint.

Acacia sentis, F. v. M., 'B. Fl.' ii., 360.—Found in all the colonies, except Tasmania; "prickly wattle." Sample obtained from Whittabramah, Tiboorra, New South Wales.

The trees of this species in the above neighbourhood are for the most part very small, and gum is found on them very sparingly. Much of it is of a rich amber colour when freshly exuded, and quite different in appearance from any other Wattle gum I have seen up to the present. Other portions are nearly as pale as selected Turkey gum arabic, while a small portion is of a dainty sulphur-yellow colour. It is sparkling and clean-looking, and would be a very acceptable article of commerce could it be obtained in quantity. This gum presents more points of resemblance to the preceding than to any other gum yet examined by me. It is very easily reducible to a powder, partly on account of its somewhat vesicular nature. It dissolves in cold water readily and completely, forming a solution of a pale yellowish-brown or amber colour.—*Pharmaceutical Journal*

SCRUB EXTERMINATOR.

I have the honor to give an account of an experiment I made last April on prickly-pear, with a small quantity of the Australian Scrub Exterminator noticed in G. O., dated 5th October 1889, No. 2287-L.

2. The manufacturers of the chemical very obligingly sent me, on my application, a sample, 15-lb. weight, free of cost, through Messrs. Oakes & Co.

3. I made two experiments, the first on the 18th and the second on 28th April, on prickly-pear growing on an open piece of ground to the south-east of the Dindigul road, just outside the toll-gate, the clump of pear selected on each occasion being vigorous, old and well developed.

4. *First experiment*.—The first experiment I need not dwell on. I used a small garden hand-syringe to throw the fluid over the pear. The suckers in the syringe were loose, a great part of the fluid escaped, and was wasted, and it could not be scattered sufficiently. I used 3 lb. of the chemical, 2 lb. in 8 gallons of water, that is, at 1 to 4, and 1 lb. in 3 gallons, that is, at 1 to 3. The only points that the experiment established were (1) that the chemical destroyed the parts of the pear that were well sprinkled, and (2) that the strength of the fluid appeared to make no difference in its destructive effect, that at 1 to 4 being just as effective as that at 1 to 3.

5. *Second experiment*.—The second experiment was more complete. For this I got the loan of a small hand fire-engine from the South Indian Railway Workshop. The engine was a little too big to get full value out of the quantity used, for the long tube from the engine held some two gallons of the fluid when the engine had ceased to work; but it answered well otherwise. The remaining 13 lb. of the chemical were put into 52 gallons of water, that is, at 1 to 4½, and pumped on the pear. When the engine ceased to work, the fluid in the tubing was poured off, and pumped on, as well as possible, with the garden syringe; and when that was done, a small part of the chemical found undissolved in the bottom was mixed with a further quantity of water at about 1 to 20, I should say, or weaker, though this could not be measured accurately; and this very weak solution was thrown over a separate small clump of young pear growing near.

6. As in Australia, the chemical produces no immediate effect on the pear. Two days after the experiment, a top leaf here and there hung down slightly browned; on the third day, though there was a smart shower of rain in the night previous, the beginning of decay was well marked; and, by the

end of a week, the whole of the area sprinkled was dead, with the exception of some thick stems in the middle, which were protected by the leaves above them, and so got little of the fluid. All the leaves were as dry as tinder, and the whole had an unpleasant smell. I had no more of the chemical to complete the destruction of the thick stems and their roots; so decided to furnish it by fire. The whole of the destroyed area was then set fire to with a little straw and rubbish; and all, including the thick stems, burnt freely. The whole patch was thus destroyed. A few sprouts have since appeared here and there in the patch; but so few and so small, that they could be destroyed by a few ounces of the fluid, or a man could dig up the roots in a few minutes and burn them. Such sprouts always appear when prickly-pear has been nominally destroyed; and the ground has always to be gone over a second time. They are much fewer than usually appear after destruction by hand-labor. The extent of the patch destroyed was 274 square yards. The small clump of young pear on which the weak solution was thrown was found killed, and it was not necessary to burn it.

7. The experiment thus proved—

- (a) that the obolical thoroughly destroys all the leaves and all the parts of the pear that it gets at;
- (b) that it destroys completely all young pear, even when used in a very weak solution;
- (c) that even old well-established pear, with thick stems, is destroyed by it so far that the destruction can be readily completed by fire;
- (d) that, judging from the Australian reports, the chemical acts a little more quickly in this country than in Australia; and
- (e) that rain has no effect in checking the decay of the plant once it has begun.

I believe also that the destruction is more complete than if done by manual labor.

8. The only question remaining is that of cost. I have had to delay this report to be able to answer the question, as the manufacturers gave me no information on the point when sending the sample. I have now received information from Messrs. Oakes & Co. that they can supply the chemical at R60 per box of 100 lb. Railway carriage would add a few rupees to this. Taking the total cost delivered in Trichinopoly at R66, the cost per lb. would be about As. 10-8. At this rate, the destruction of the 274 square yards costs as follows:—

	RS. A. P.
12 lb. of the chemical at As. 10-8 ..	8 0 0
Cost of burning—	
6 Coolies	1 2 0
Fuel	0 14 0
Total ..	10 0 0

Or just 7 pies per square yard—a little more than the usual rate for destruction by manual labor, viz., 6 pies.

9. So far, therefore, it would not pay to use the chemical. I believe, however, that the chemical could be used much more economically; and that a strength of 1 lb. to 10 gallons of water would be just as destructive. It would be slower in action, but that is of no consequence. I could not unfortunately prove this, except on the clump of young pear, for the fire-engine was so large that I had to put all the remaining stuff in. The cost of burning too would, the Tahsildar tells me, be only one-half the figure given in villages away from Trichinopoly town. Taking that as correct, the expense for 274 square yards would be—

	RS. A. P.
5 1/2 lb. of the chemical at As. 10-8 ..	3 7 6
Cost of burning	1 0 0
Total ..	4 7 6

Or 3 1/2 pies per square yard; or including a cooly to work the pump, an item I have not taken into consideration, as the South Indian Railway Company have not charged me anything, the cost would be

something under 3 1/2 pies per square yard. That rate would pay. Another item I have not considered is the initial cost, and occasional repairs, of one or more suitable pumps; but this would make very little difference in the cost per square yard when distributed over any considerable area. Cartage to a long distance from the railway would, of course, raise the figure.

10. The most suitable pump, I think, would be a garden watering pump, on wheels, to hold about 12 gallons. One man could easily wheel about and use a pump of that size without assistance.

11. On the whole, the chemical is not, I fear, cheap enough to supersede destruction by manual labor altogether; but I think it may be used with advantage, even at its present price, in places near the railway. I propose asking the Local Fund Board to put a small sum of R100 or so at my disposal for the purpose of making further experiments with weak solutions when the dry weather comes. I shall report the result.

12. I shall also ask Messrs. Oakes & Co. whether they cannot reduce the price.

Resolution—dated 28th November 1890, No. 369.

The Board is much indebted to Mr. Fawcett for the care with which he has carried out the experiments described above. They leave no doubt that the chemical is most efficacious in destroying prickly-pear in all stages of its growth; but, as Mr. Fawcett points out, its present cost is too great to allow of its being extensively introduced into a country where labor is generally cheap. He states that taking the price of the chemical alone at the figure given by Messrs. Oakes & Co., viz., R60 per box of 100 lb., and excluding the cost of pump, &c., which are essential to the success of the experiment, the cost of destroying the prickly-pear came to 7 pies per square yard as against only 6 pies, which is the usual cost of destroying it by manual labor. It would seem, however, from the report printed in G.O., dated 6th September 1889, No. 764, that the quantity of the chemical used by Mr. Fawcett, viz., 12 lb. in 52 gallons of water for 274 square yards, was somewhat excessive. Mr. F. Piper, Head of the Forests Branch, Department of Lands, Victoria, considered an application of the chemical by Mr. Brodie, Prickly-pear Inspector, at the rate of 240 gallons of the solution (containing 80 lb. of the chemical) per acre, to be *twelve* times as much as the quantity named by the proprietors (if the patent as sufficient, viz., 6 1/2 lb. dissolved in 20 gallons of water. The quantity of the chemical applied per acre in the experiments in Trichinopoly was about 212 lb., that is nearly *thirty-two* times as much as the quantity named by the proprietors as sufficient. Both in Australia and in Trichinopoly, it has been found that a solution of 1 lb. of the chemical in 6 gallons of water was as good as a solution of 1 lb. of the chemical in 3 gallons of water. For destroying young clumps of prickly-pear, Mr. Fawcett found a solution of 1 lb. in 20 gallons of water quite sufficient. What the weakest solution capable of killing prickly-pear in this country is has yet to be determined.

2. In Australia, prickly-pear of a species which attains a far larger size than that usually found in this country was found to be completely killed in from 8 to 10 days after the application of the chemical, and it was found that it acted there much more speedily during hot weather than in cold weather. The Collector of Trichinopoly found an old clump of prickly-pear completely killed in about a week after the application.

It appears from the Trade Circular issued about the chemical, that its cost in Melbourne is £2-10-0 per 100 lb. which, at the current rate of exchange, is equivalent to about R33 1/2. The cost might probably not exceed R40 per 100 lb. delivered at Madras. Even if the chemical be applied at thorato considered very excessive, at which Mr. Brodie, Prickly-pear Inspector, effected the destruction of old clumps on 1/4 acre of land, the cost per square yard on account of the chemical would probably not exceed 1 1/2 pies. Of course, if 6 1/2 lb. of the chemical

be enough for an acre, as the proprietors of the patent appear to think, the cost per square yard for the chemical will be a mere trifle.

3. Since these proceedings were drafted, a small quantity of the chemical (a little over one pound) has been received from Melbourne with G. O., dated 29th October 1890, No. 845. This will be tried at Suidapet under the supervision of Mr. Keess and Sub-Assistant Director Mr. Subba Row at a strength of 1 lb. in 6 gallons of water applied to 60 square yards which is the rate which has actually been found to be effective in Australia. According to the proprietors the same solution would seem to be sufficient for about twelve times the area. This will also be tested by actual experiments as far as possible with solutions of the chemical varying in strength from 1 lb. in 6 gallons to 1 lb. in 20 gallons. The latter strength was found to be sufficient for killing young prickly-pears at Trichinopoly.

4. One important point which should be carefully borne in mind in making these experiments is that a solution of the "Scrub Exterminator," if allowed to come in contact with the skin, causes some abrasion, and if allowed to come in contact with the finger nails causes much pain, and that cattle are apt to be poisoned if they eat scrub or grass saturated with it. The proprietors state that stock should not be allowed access to the ground operated upon for about a week.

REPORT ON THE COCONUT DISEASE AT MONTEGO BAY.

Botanical Department, Gordon Town P. O.,
24th July, 1891.

Sir,—I have the honour to report that I have visited Montego Bay to examine into the death on a large scale of Coconut Palms in that neighbourhood.

Several trees were cut down, and the roots, stem, leaves, and cabbage examined. There was no evidence whatever of attacks by a beetle, there were some small larvae, some wood lice, earwigs, ants of several species and other insects on the affected parts, but they were evidently only preying on the diseased juices, and were not the cause of the disease.

The roots were quite sound and the stem appeared to be unaffected. Both stem and leaves were of normal size, and there was no indication of a gradual dwindling of vitality due to lack of proper nourishment extending over a long period. The disease, whatever it might be, seemed to be quick in destruction.

The youngest parts were those affected. The leaves and flowers in the bud were sometimes able, though affected, to withstand the disease so far as to open out, and some leaves and nuts attained almost their full development before the tree succumbed. In the case of tall trees, the first indication of the disease was the dropping of the young fruit. It was stated that the disease in this condition had been checked by setting fire to the fibrous material at the base of the leaves, which process burnt all the leaves; new fronds, however, developed, and the tree was at any rate for the time saved. The application of salt to the cabbage had also, it was alleged, been successful.

If the terminal bud in the cabbages is affected, the tree is doomed.

In almost all the trees examined, the sour smell of a putrefactive fermentation was very noticeable, and I am of the opinion that the disease is due to an organised ferment which is able to attack the very tender tissues of the youngest parts, even outside the terminal bud. If this ferment can be destroyed by fire or other means before it reaches the terminal bud in the heart of the cabbage the tree may be saved.

Any remedy should therefore be applied on the very first signs of disease. If delayed too long until the terminal bud is diseased, the tree cannot be saved.

Although to fire the fibre at the base of the leaves is easy of application, it is not safe near buildings, and by the destruction of the leaves, the production of fruit is for a long time retarded with consequent loss.

I would recommend that those who do not care to apply fire should drench the cabbage with a solution of sulphate of iron in water in the proportion of two pounds of sulphate to one gallon of water. A solution of sulphate of copper might also be tried in the proportion of 5 parts to 100 of water and a solution of boric acid in the proportion of 4 parts to 100 of water.

All diseased trees which cannot be saved, should be cut down and burnt, to prevent infection.

In order to give the tree every chance of recovery the soil might be scraped away from the roots and the ashes of the burnt trees applied together with some manure.

It may be said that these remedial experiments are costly, but on the other hand the annual value of each tree is stated to be at least four shillings.—I have, &c., (Signed) W. Fawcett, Director of Public Gardens and Plantations.

The Hon'ble the Colonial Secretary.

COCOA: SAMPLES FROM LONDON MARKET.

The following correspondence transmitted by the Secretary of State for the Colonies to the Jamaica Government on the subject of Cocoa has reference to samples received from Messrs. Wilson, Smithett & Co., through the kind offices of Kew. The samples have been placed in the Museum of the Jamaica Institute for ready inspection by those interested.

Royal Gardens, Kew, to Colonial Office.

Royal Gardens, Kew, 1st July, 1891.

Sir,—I am desired by Mr. Thiselton Dyer to inform you that he has received from Mr. W. Fawcett, Director of the Botanical Department, Jamaica, an application for samples of commercial Cacao as it is usually received in the London market, for the purpose of bringing before planters in Jamaica the appearance and quality of Cacao which receives the highest prices.

2. In furtherance of Mr. Fawcett's wishes application was made by this Establishment to a firm of brokers in the City and the enclosed report, with a set of samples, has been received from Messrs. Wilson, Smithett & Co. The samples are being forwarded direct to the address of the Director of the Botanical Department, Jamaica, by the outgoing mail.

3. The Cacao industry in Jamaica has steadily extended of late years. The quantity of Cacao exported has increased fourfold, but the value per cwt. has been almost stationary. In fact it has become a matter for serious consideration to the Government of Jamaica how it may be possible to rescue an otherwise promising industry from being crippled by the carelessness of the small proprietors, (who at present grow the bulk of Jamaica Cacao) in exporting an inferior article.

4. In an address given at the request of Sir Henry Blake at the late Jamaica Exhibition on February 9, I drew particular attention to this subject and pointed out that owing to bad curing Jamaica Cacao was at the bottom of the list of Cacao in the London market, and the Island lost yearly on this account about £20,000 to £30,000. Acting on my suggestion then given, the Government has lately taken steps to send intelligent instructors round the Cacao growing districts to explain carefully to the settlers the way the Cacao should be cured, and the Legislative Council has voted a sum of £600 for this purpose. The result of this experiment will be watched with some interest.

5. As confirming the information placed before the Government of Jamaica it will be noticed that Messrs. Wilson, Smithett & Co. report that the bulk of Jamaica Cacao "is of very ordinary quality"; the only West Indian Cacao taking rank below it, being St. Domingo from Jeremie, "whilst that from Samana in the same Island is superior to Jamaica.

6. Owing to the facility with which Cacao can be grown under the shade of bananas, the extension of Cacao planting in Jamaica should proceed *pari passu* with that of fruit culture. The little attention, however, so far devoted to properly curing the produce is a matter of grave concern to those interested in the Island, and it is to be hoped that the measures now in course of being taken to remedy the defect will produce results of a more hopeful character.

I have, &c.,

Edw. Wingfield, Esq C.B., Colonial Office, Downing St
(Sgd.) D. MORRIS.

Messrs. Wilson, Smithett & Co., to Royal Gardens, New,
41 Mincing Lane, London, E.C., 25th June, 1891.

Sir,—We duly received your letter of 11th instant requesting us to supply for the Government of Jamaica, commercial samples of the various sorts of cured Cacao which come into the London market, and we have much pleasure to advise you that we have despatched four samples, the best of the respective kinds to your address, viz:—

No. 1. Fine Ceylon, value 15/ per cwt., from Alooihare Estate.

No. 2. Fine Trinidad, value 98/ per cwt., from Locounseo Estate.

No. 3. Fine Grenada, value 65/ per cwt., from Tuften Hall Estate.

No. 4. Fine Guayaquil, value 90/ per cwt., from Arrila Prima Estate.

We have not included a sample of Caracas, as that growth is generally cured in the earth of the country and attempts made in various places to prepare Cacao in that manner have almost invariably ended in a disappointment. A small proportion of Jamaica Cacao imported here has undergone fermentation to a greater or less degree, but the bulk is of very ordinary quality, the only West Indian Cacao taking rank below it being St. Domingo from Jeremie, whilst that from Samana in the same Island is superior to Jamaica. It has however all the characteristics of good Cacao—although wanting in size, and if properly harvested, fermented or sweated, and then dried in the sun until the bean becomes crisp to the feel, so that the shell is fairly loose, and the interior dry and of an even chocolate brown, not violet colour when broken, it should command the general attention of Trade. Great care should be taken to protect it from rain whilst curing. It must be noted that manufacturers cannot pay much attention to small parcels, and that to insure a ready sale not much less than a ton weight of even colour and quality should be shipped, the larger the lot the better.

We are, &c.,

(Sgd.) WILSON, SMITHETT & CO.

D. MORRIS, Esq.

ANOTHER COFFEE PEST.

In view of what has already been so successfully attempted in the experimental gardens of Mergui, and also with reference to the prospect of the increased cultivation of the coffee plant in the southern districts of this province, it may not be without some interest, even to general readers, to become acquainted, in some slight degree, at least with an insect pest that has only recently been found to work great mischief and loss in the coffee plantations of distant Guatemala. We are indebted to the interest taken in this matter by our Consul in that state, Mr. Arthur Chapman, who has embodied in his last annual report, the report of the scientist, M. Vendrell, a member of Belgian and Spanish Agricultural Societies, and who made his investigations, by order of the local Government, of Guatemala, in the plantations in the Department of Amatitlan where the disease caused by the insect pest, had resulted in extensive ravages in the coffee plantations.

Coffee is one of the chief articles of growth in Guatemala, where also the cochineal insect is obtained, in immense quantities for export, on the numerous members of the Cactus tribe, so common on the virgin soil of that country. And, it is not

a little strange, that the pest, so much complained about as a "new and hitherto unknown trouble," should be so much like the cochineal insect, which is such a prolific source of local wealth. The insect, called a "chinch" or "bug" by the agriculturists, is declared by M. Vendrell to be "a standing menace to the coffee industry," and is therefore well deserving of attention by all coffee planters. The genus to which the pest belongs—the *Coccidae*—not only includes many species which are highly injurious to plant-life, but not a few which have come to be of use to man. Among the latter are the *Cochineal*, already referred to, the *Lac*, which is found in such abundance in our Shan State; the *mannu* growing where few forms of civilised life are to be found, though in some places largely replaced by exodations from such trees as the ash and tamarisk; and lastly the *Chinese War* insect so remarkably peculiar in its habits as well as in its produce of wax in parts of China, like Si-chuen.

As general characteristics of the genus we may note the want of wings in the females, the degeneration of the stercorial proboscis posterior wings in the males, and the peculiar life-history of both sexes. In the early stages of their growth they are in form like miniature tortoise-shells, and may be seen running all over the plants they affect. Soon, the females become impregnated, and then they settle down to the work of maternity on the branches and leaves, burrowing their suckers deep into the tender tissues in order to imbibe the nourishment they require from the juices of the plant. Henceforward the females do nothing but feed and breed; and the latter process is so wonderfully prolific that the ova of a single female, looking at certain seasons like a pinch of dry dust, number very often millions. When in this state the wind blows this living dust about in all directions, and not unfrequently the careful gardener finds a favourite rose or plant, which the evening before he had left quite clean and healthy, covered in the morning by multitudes of these insects seeming to have come into existence magically. The matured females often become quite plump and fat, looking like berries, but more generally they form distinct excrescences, some round and plump, others flat like scales. At the present time in Rangoon a species of these scale-insects may be found on the back of rose leaves. They look like black dots, and frequently have a margin of white. Under a magnifying glass they may be watched with a "good deal of amusement and instruction. The popular name by which these insects are known is scale-insects."

The coffee scale-insect, which has lately caused such consternation in Guatemala, appears as small galls or excrescences similar to small tortoise-shells on the edges of which are small double points. Under a microscope the back shows a central crest traversing its length, and also a number of small points covering the whole surface, just like what may be seen on some marine shells. Its color is variable. When first noticed, unlike the rose-leaf scale, it is of a reddish color, but becomes a dark yellow as it grows in size and develops its eggs. In its last stage it becomes the color of the bark of the coffee plant, and this is so when the insect dries and its outer shell becomes thin, ligneous and fragile. If the yellowish liquid, contained in the body of the mature female, be examined under a microscope, it will be found to contain thousands of little eggs. If a dry insect be opened there will be seen a little, very fine, dry powder of a reddish yellow color which is transported by the wind in somewhat the way in which the pollen of flowers is wafted. From each egg issues a maggot, and this goes through its transformation like the generation which gave its birth.

It is said that when the insect first takes possession of a coffee plant, it is barely noticeable; but after a time an infinity of small red spots appear in the trunk and branches, and these increase in size daily until they attain their normal dimensions. Then it is that the coffee

plant becomes abnormally yellow, a characteristic sign of some form of disease, or the presence of some animal with which it has to struggle for life. On examination now the plant is found to be the victim of the coffee-scale. The berries produce by such plants, if produced at all, are small, few and worthless. A noticeable thing in connection with the presence of the "scale insect" is that attacked plants and fruit mature much earlier than sound plants, but, as stated, the fruit is worthless. Nearly fifty per cent. of their crops have been lost by the planters through the ravages of this insect.

As for remedy M. Vendreil recommends the use of nitrates as manure for the soil, but he says nothing as to means for destroying the insect itself. In America an emulsion of kerosine oil has been found very efficacious in cases of some the "scale-insects."—*Rangoon Times.*

THE IMPROVEMENT OF TREES.

It can hardly be doubted that trees whether grown for timber or for ornament, can be improved by methods similar to those which have been used for the development of our modern fruits and vegetables, and that the time must come when the same attention will be paid by scientific foresters to the improvement of races of timber-trees as is now paid to the improvement of plants of far less importance to the human race.

There are certain individuals of every species of plants which, for some reason or other, grow more vigorously than others or possess other exceptional qualities. This fact has been taken advantage of to establish new races of garden-plants, but in the case of trees it has been too generally overlooked, and sufficient attention has never been paid to the selection of the seed-bearing parents, the mothers of future forests. The whole question of the improvement of trees, whether as producers of timber or merely as ornaments of gardens and parks, is still before us. Humbler plants often gain hardness by the mingling of the blood of allied species, and what little has been learned of the few natural hybrid trees known to exist shows plainly that it is within the bounds of possibility to produce trees artificially by hybridization which may possess certain qualities to a greater degree than either of their parents. Then there is the whole question of the relation of the stock to the graft as applied to the production of timber-trees to be investigated. It is known that certain trees, when it is desirable to produce them under certain conditions, grow much more rapidly and vigorously, while young at least, if they are grafted, than they do on their own roots; but time and careful observations are needed to determine what results, from economical points of view, will finally be obtained by such a method of propagation.

All such questions as these are matters which must one day occupy the attention of scientific foresters, and which can only be solved at well equipped forest-stations, which all governments, following the example of Germany, can wisely establish; for without the stability which governments alone can give, scientific observations, demanding a longer period than the life of one generation of men, are apt to be barren of useful fruit.

Such thoughts naturally lead us to consider whether it is not possible to increase the number of ornamental trees to be grown in any particular region and the beauty of individuals by the application of the same rules of selection of seed from exceptionally fine individuals as we now employ in producing cabbages or radishes. This seems such an evident proposition that it requires no argument to support it; and yet how few persons who raise trees from seeds pay the slightest attention to the character or health of the individual which supplies them. For the ordinary collector of tree-seeds in the nursery or the forest a seed is a seed, and the fact is ignored or forgotten that the consti-

tutional weakness of an individual plant can be transmitted through its seed. Neglect to properly select the seed-parent is doubtless the cause why many nursery-grown trees fail before their time, and why seedlings raised from trees subjected in cultivation to more or less unnatural conditions are less desirable than those raised from individuals growing spontaneously under the most favorable natural conditions.—*Garden and Forest.*

EXAMINATION OF OIL OF CASSIA.*

BY H. GILBERT.

It is pointed out that oils of cassia and cinnamon may be highly adulterated with resin oils and still pass the tests of the German Pharmacopoeia. With nitric acid, sp. gr. 1.45 at 15°, or with 1.50 acid at 60°, both the pure and impure oils give crystals without development of heat; however, with the 1.50 acid at 15° both react violently, with development of heat and without the formation of crystals; therefore, the P. G. test, as neither the sp. gr. nor the temperature of the acid is stated, may lead to the condemnation of a pure oil and *vice versa*. By determining the "acid number," the adulteration can be detected, as the following numbers show:—

	Acid numbers.
Genuine oil of cassia (with 6 per cent. non-volatile residue)	13
Genuine oil of cassia after 40 hours' aeration	13
Genuine Ceylon oil of cinnamon (2 per cent. residue)	9
Genuine Ceylon oil of cinnamon (2½ per cent. residue)	10
Adulterated oil of cassia (28 per cent. residue)	47
Adulterated oil of cassia (prepared from pure oil of cassia by intermixing 20 per cent. of eolophony)	40
Eolophony, sp. gr. 1.08	150

—*Pharmaceutical Journal.*

ECHOES OF SCIENCE.

Dr. Paul Gibier, director of the New York Pasteur Institute, has issued his report for the six months from February to August of this year. Of 415 patients who applied for treatment, no fewer than 345 were found to be suffering from needless alarm, as the dogs which had bitten them were not mad. The remaining 70 cases were put under the Pasteur treatment, as the bites were really due to hydrophobic animals. Only one death took place. That of a child five years old, who had been bitten in nineteen places by a mad dog. Three other persons, namely two sisters of the child and a man, who had been bitten by the same dog, were also treated, and are now alive and well.

Peat promises to become a very useful article. In a recent number of the *Handels Museum* Dr. Leo Pribyl states that the Germans and Swedes are utilising their peat bogs in the manufacture of naphtha, tar, solar oil, paraffin, acetic acid, and gas. Moreover, the peat yields an elastic fibre which, freed from dust, is employed for weaving into carpets. Good peat also furnishes a cellulose which is valuable to paper makers. Besides serving as a wholesome litter for live stock, it is also used to preserve perishable goods. Meat and fish are now packed in peat litter for transport between Trieste and Copenhagen. Here is a matter for the consideration of Irish landowners, and peasant proprietors as well. The Franco-American Cellulose Manufacturing Company, of Philadelphia, have a process for making coconut cellulose which absorbs eight times its weight of water. It is intended for use in lining vessels, and it is difficult to make a hole through it.

The Journal of the Camera Club for December contains a paper by Mr. G. L. Addenbrooke, on the advan-

* *Chem. Zeit.*, xiii., 1406-1407. Reprinted from *the Journ. Chem. Soc.*, April.

tages of aluminium for photographic lenses and the metal parts of cameras. Being so light it reduces the weight of the fittings to nearly one-third. He suggests its use in place of wood for the dark slides, and also for developing dishes, as it is very little affected by the chemicals employed in photography. Any compounds that might be formed would not vitiate the picture.

The first scientific account of the great earthquake in Japan has been given by Professor John Milne, the well-known seismologist, of the University of Tokio. Mr. Milne was awakened at 6-38 a.m. on October 28th last by the oscillations of his house which produced a sense of dizziness and nausea. As recorded by his bracket seismograph, this continued for ten or twelve minutes. On examining these instruments, he found that they were acting very imperfectly, and failing to record the horizontal displacements, which in this case were accompanied by vertical motions.

Mr. Milne's letter, which has appeared in *Nature*, and is dated November 7, bears witness to the admirable self-command of the Japanese. There was no panic among the people of the district, although the earthquakes were in progress when he wrote, and no helplessness from hysteria or mental prostration. They hear the "boom" announcing a shock, and "run laughing into the middle of the street." "As to what happens with Europeans under like circumstances," says Mr. Milne, "I must leave readers to consult history." Foreign buildings of brick and stone have suffered severely; cotton mills have fallen in, and their chimney stacks have broken at half their height. Cast iron columns supporting bridges have snapped near their bases; masonry piers have been destroyed in a similar manner; embankments have been shot away, brick arches have collapsed, and railway lines have been twisted into snaky folds and vertical waves. In the cuttings near the hills, however, the railway tract is unaffected. Here and there a Japanese temple or castle has escaped destruction, owing, Mr. Milne thinks, to the superior quality of the woodwork and jointing. The greatest havoc has taken place on the Okazaki-Gifu plain, where the opening of crevasses, the spurting of mud and water, the falling in of river banks, and other phenomena, marked the violence of the earthquake.

Kelway's system of signalling by night at sea has the merit of simplicity. A board is studded with electric incandescent lamps, and the connections to the lamps are so arranged that in order to signal a given letter (say N) the lamps forming a group N are lighted. There is a keyboard for sending the currents into the proper lamps, and the keys are played like those of a type-writer. As most large vessels are now furnished with electric lighting plant, the system is in a fair way of being taken up and tried.

The surveys for the proposed railway from Mombasa to the lakes of Central Africa will be commenced at once under Captain J. R. Macdonald, R.E., and a staff of Indian pioneers (with native servants), lent by the Government. The work will be undertaken by the British East Africa Company. The surveys for the proposed line from the Pangwe River to Massi Kesso have already been made. The railway will start from the Pangwe at a point opposite Inhambanu and run to Ioho on the River Busi, thence across the wooded plains between the Pangwe and Busi. It will be the work of the Mozambique Company, and the British East Africa Company's line to Fort Salisbury will branch from it.—*Globe*.

THE CLOVE AUCTIONS IN ZANZIBAR.—Further particulars have now been received of the first public sale of cloves at Zanzibar. The Auction, as we have already announced, took place on November 21, at 9 a.m. The cloves offered were Government property, having been tendered as "payment in kind," in discharge of export duty. Mr. Gerald Portal and General Matthews attended the sale, and before it began Mr. Portal addressed the mer-

chants, briefly pointing out that the sale of Government property about to take place, though small in itself, was really most important as making a new departure in the trading system of Zanzibar. It was he hoped, one more important step towards the development of the commerce of Zanzibar. Mr. Portal expressed his firm belief in the practicability of making Zanzibar a great central market for Africa, and in conclusion stated that in a very short time the Government hoped to remove the few remaining restrictions upon trade here, when he said, all ideas of rivalry or jealousy between Zanzibar and the coast territory must cease as the prosperity of one would tend to the prosperity of all. The sale was well attended by all European and Indian merchants, and the stock offered was disposed of at fair prices although heavy purchases for Bombay, during the early part of the week, somewhat restricted the demand. Pemba quality realised \$2-36 to \$2-40 per freziloh, and Zanzibar (new crop) \$2-60. The management of the sales was in the hands of Mr. Hugh C. Robertson, the Receiver of Revenue for the Zanzibar Government. The first sale proved a decided success, and it is hoped that the public auctions which are to be held fortnightly will prove a beneficial change from the plan formerly followed by selling the cloves privately.—*Chemist and Druggist*, Dec. 18.

CINCHONA CANKER AND QUININE FACTORIES IN BRITISH INDIA.—Mr. Lawson the Indian Government botanist, is now or was when the last mail left in the Wynnad district of India engaged upon some interesting experiments for the cure of canker in cinchona. The quinine manufactory at Nedivatam has been a success and there is a rumour that a somewhat similar one is to be established in South Wynnad on the co-operative system by the planters. There should be no difficulty (a correspondent thinks) in accomplishing this work and the saving to the planters would be very considerable; the cost of carriage would be reduced to a minimum and all the money now paid for baling and shipping bark and to agents for analysing and selling would be saved—to the tune of 25 per cent. or more. With a quinine manufactory and two or three capacious tea factories established in the country the Wynnad may yet be rehabilitated and something like the old prosperous days may be restored to the planters.—*Chemist and Druggist*.

SIAM'S FOOD SUPPLY.—Referring to the scarcity of rice the *Bangkok Times* says:—Burmah has ceased to export; Tonkin is unable to supply anything like the quantity she did last year; Japan needs nearly all she can harvest in this period of calamity; the crops in the Philippines are barely sufficient for the sustenance of the inhabitants, despite all the inducements in the shape of bounties offered by the Spanish Government; and in Siam, judging from the official reports, we shall be lucky if this harvest produces one-fourth the average yield. In the Patwari district it is true there has been an excellent crop, but we are assured that elsewhere not more than one twentieth of the expected crop is to be expected. That being fully required for the sustenance of the population here, surely the Government will do well to take precautions against possible scarcity by prohibiting the wholesale exportation which is going on owing to the high prices now offering in the surrounding countries. Last month three hundred and seventy-five thousand piculs of rice, valued at nearly 750,000 dollars, left Siam—two-thirds of it for Singapore. In the corresponding month of last year, with a moderately bountiful harvest, the export was only about a quarter more,

Correspondences.

To the Editor.

TEA DUST EXPORTED IN BAGS.

London, E.C., Dec. 4th.

SIR,—Yesterday we received into our warehouse the tea dust which had been packed for us by Messrs. Buchanan, Frazer & Co., Colombo, into cotton canvas bags, christened. W. R. Appleton & Co., tea dealers in the City, came in and examined the packages, took samples and tasted the tea and expressed themselves very much pleased, as it was in splendid order. I think that this will show that tea dust can be safely sent home in bags if properly waterproofed with a material which has no smell whatever. Other tea brokers examined the tea and pronounced it in very good condition because the packages were air-tight; they said that if they gave me a report there would be an upset in the trade. Some people fear to advance out of the old groove.—Yours truly,

THOS. CHRISTY.

MR. LIPTON AND THE CHICAGO EXHIBITION.

Dickapittia, Haputala, Dec. 14th.

SIR,—The following was embodied in a letter received by me yesterday. It is possibly not yet too late to suggest the name of Mr. Lipton in connection with our representation at the Chicago Exhibition. As is well-known he is a capitalist with large established interests in that city, also that he is one of the largest if not the largest tea dealer in the United Kingdom, moreover that he is interested in Ceylon.

But selling an article which is considered the best value in the trade and which owes its excellence to the mixture of Ceylon tea in it he has gained in a few years the prominence he now occupies in the trade. It would no doubt benefit the industry on which Ceylon is chiefly dependent if the influence of a capitalist like Mr. Lipton with his interests in Chicago, Ceylon and in the tea trade could be secured. The suggestion may be objected to on the grounds that it would be advertising Mr. Lipton, who may possibly start on his own account to boom his teas in America; but as they are largely a mixture of Ceylon tea and those now consumed in that country are almost entirely Japan teas every pound he sold would benefit this country, and extended consumption of our produce is what we want whether pure or as a mixture.

We have just received the telegram announcing the unanimous selection by the Planters' Association of Mr. Grinlinton as Commissioner to Chicago. I am sure he would be glad of Mr. Lipton's co-operation.

The idea above expressed seems to be an excellent one; and if you think so, Mr. Editor, I trust you will ventilate the matter and give it your support.—I am, dear sir, yours faithfully,

JAMES DUNCAN.

[We have no doubt that Mr. Grinlinton, if appointed Commissioner, as he is pretty sure to be in deference to the wishes of those connected with our chief enterprise, will give full consideration to this suggestion. But if Mr. Lipton's co-operation is invoked it will undoubtedly be on the principle of promoting the sale of pure Ceylon tea, unblended and unmingled with any other. This as we showed recently, Mr. Lipton does not do,—all the teas he

advertises in his circular are blends.—Since writing the above we have seen the proceedings of the Tea Fund Committee, amongst which is a notice of the withdrawal of subscription on account of Mr. Lipton's Pooprasie group of estates. This, we should say, settles the question of Mr. Lipton's attitude in regard to the Ceylon tea enterprise. He is interested in our tea, no doubt, but only as it serves his own personal profit, in the shape of a blend; such are not the men to help in extending the use of pure Ceylon tea.—Ed. T. A.]

TOBACCO IN NORTH BORNEO.

Kandy, Dec. 22nd.

DEAR SIR,—The last advice I have from North Borneo re tobacco is as follows:—"We are glad to say that our North Borneo tobacco is topping the market and beating Sumatra. Although the prices paid, in the face of 40,000 bales, are low, it is satisfactory to know that they are better than others. We are expecting an Australian-China steamer here on the 6th, to load timber for the Australian market. The latest reports from the tobacco estates are encouraging. The weather continues favourable, the rains having not set in yet. Mr. Pryor returned from England yesterday representing a planting and development company."—Yours truly,

W. D. GIBBON.

THE PRICE OF PEKOE SOUCHONG.

DEAR SIR,—Now that we are on the job we may as well thrash this matter out to the end, especially as "A Buyer" has dropped the mild sarcasm usually indulged in by tea buyers when noticing any animadversions dating from upcountry. This is novel and refreshing, and I will endeavour to imitate his moderation. The fact that my first letter caused him genuine surprise simply goes to show how little sympathy exists between tea buyers and tea producers. Well, I will not lift much of the curtain to show all that is behind it; but to suppose that there can be much community of "feeling" between a buyer getting a haul of average pekoe souchong at 22 cents a pound (while the equivalent London value is 30 cents)—and the planter whom it has cost 30 cents to produce, is of course out of the question. "Well, but it is not so," says "A Buyer," "our margin is much smaller than that." What the margin is with which he is satisfied is not stated, unless we may infer it from the 53d sample sent to him as his "buying standard" up to 25c. This would leave a loss! instead of 8 cents profit, against which I for one have nothing to say.

But WHY "Buyer's" principals in London should send him out a "standard sample" at 53d when the London average is for "one uniform quality, which never varies," as he asserts, and is at the time quoted 63d remains for "A Buyer" to explain. The instructions look like:—"buy quotable Pekoe Souchong at 25 cents."

But may I ask "A Buyer" not to wander too far afield. I might as well ask him to come upcountry and grow tea (which perhaps he does, by the way—such things are!) as he to ask me to "buy" at any price, while I am in the position of being obliged to sell at any price. If this were not so then "A Buyer's" occupation would be gone. Notwithstanding all that "A Buyer" has said—and I think his letter is fair and candid—he has not yet answered my question. I have looked for, but cannot now find the qualifying words which formerly appeared on the London Price Lists, namely:—"Fair Pekoe Souchong of the quality usually made in * * * factories." Now this description of the

"quality" quoted has always stuck in my memory, and I do not think it will be denied that the factories designated have a low average. If such Pekoe Souchong soils in London at 6½d, and this, as you, sir, figure it out, is equivalent to 30 cents locally, I cannot understand why it should only realize 22-24 locally, except that at the Colombo sales there is no fair and healthy competition. But as I remarked before, neither "A Buyer's" laboured explanation nor my growls can throw much more light on the subject. There is, however, after all, not much mystery about it; and if I were a buyer I should not need to ask

WHY?

RICE CULTIVATION.

Jan. 2nd.

DEAR SIR,—There seems to be a deal of misapprehension regarding the system of dry ploughing and about the yield of paddy and other grains generally.

When crops are spoken as 'so many fold,' it always bears a relation to the quantity of seed used in sowing. As regards paddy in ordinary cultivation, 1 to 3 bushels are sown per acre. The quantity used always depends on the nature of the land, the season and the variety of paddy. In rich and fertile lands only a small quantity of seed paddy is used, the case is especially so if the season is favourable. On the other hand when the land is unfertile and the season is unfavourable a larger quantity of grain is used for sowing. It has to be borne in mind that whatever the quantity of seed be, which is scattered over the land, only a certain proportion of plants do come up. An acre of paddy field can never under any circumstances hold a number of plants over the number of grains of paddy from say a quarter bushel of seed. If an acre of land is sown with one bushel or three bushels, the plants which survive cannot count over the number above mentioned. That would be the highest possible number, but in the majority of cases it is very much less. The rest of the seed grain is simply wasted.

Unless any sowing machine or a seed drill be used and until the proper selection of seeds is carried out, the necessity of sowing a larger quantity of grain than is actually required must continue to exist. Out of the grain thrown on a well prepared rich land a great number comes up, while when the land is unfertile and the season is unfavourable only a smaller number germinates. That is the reason why a large quantity of seed grain is scattered on inferior soils. The above I believe is the cause of much misunderstanding as regards the yield of paddy in different areas. When mentioned by folds, the quantity always depends on the amount of seed paddy used. So the adoption of a yield per acre for calculation purposes would be much better, as things stand just now.

But it is deplorable that there is such a waste of seed paddy, and it was I believe one for Mr. Green's first plans in the improvement of rice cultivation to advocate the use of seed sparingly. Even as matters exist the quantity of seed grain could be very materially reduced, and if selection of seed is practised, a greater saving could be made, but if seed drills and sowing machines are introduced the quantity would be still more reduced, whilst the transplanting system wherever it could be adopted would bring the waste to a minimum.

The above applies with the same force to kurrakkan and other grains. The finer the grains are there would be a larger number of seed, measure for measure: for instance a measure of kurrakkan would contain over 15 times the number of seed contained in a measure of '6 months' paddy,' whilst a measure of small grained '2 months' paddy,' would contain about twice the number. Hence each of these varieties would produce a varying number of plants in spite of the quantity being the same. The land has almost nothing to do with seeds, but to support the plants. This explains why a much smaller quantity of fine grain is used in sowing a given extent of land.

Your correspondent "Native Cultivator" does not seem to favour dry or deep ploughing, and he naturally sticks to the much easier process of stirring up the mud when the land is thoroughly soaked. Some of his arguments against the adoption of the improved system have been put forward more than once in your columns. I remember that some years ago almost the same arguments were brought forward, and Prof. Wallace's authority was cited in support. But so far as I am aware the Professor never wrote or spoke against the advisability of dry and deeper ploughing. It is said that dry ploughing would throw up lumps of clay which it would be difficult to pulverize. Lumps of earth would be turned up by the share of an improved plough no doubt on some lands, but if these lumps are not allowed to be baked in the sun, there cannot be any difficulty in pulverizing the same. In such lands the clods should be pulverized just after the ploughing and then exposed.

The great drawback in our native system is that whilst it prepares a suitable seed-bed, it does not expose the soil to the action of the sun and the atmospheric agencies, which action alone could make a soil fertile. The weeds buried by the native plough might decay but they very seldom form a suitable manure; on the other hand the action of the water makes them to decay and stagnate and generate objectionable organic acids, whilst in the case of dry ploughing the weeds and rubbish disintegrate and form a manure without generating anything objectionable. Your correspondent again says in one place, "that the native plough digs deeper than the improved plough." It might in some instances, when the land is soaked, stir up the mud deeper. But such deep stirring is quite useless and sometimes objectionable, when the land is not exposed to the action of the sun. What the improved plough does, so far as I have seen, is that it does not dig deep, but exposes a larger quantity of soil, thereby increasing the quantity of plant-food.

As your correspondent mentions, the villagers also have a system of dry cultivation which they generally adopt whenever they fail to obtain the water necessary for soaking the fields. This is known as *kekulan* sowing.

When lands are dry sown according to the native system they at first give very good crops, but in some cases when the dry system is continued, as your correspondent observes the land yield poorer and poorer crops. But in other instances, such as mentioned by Mr. Elliot they continue to yield good crops. This is very easily explained; in the first place it should be mentioned that in the native system of dry cultivation not more than two to three inches of the soil is stirred. At first the land yields a bumper crop as the soil is exposed and a large quantity of plant-food is liberated; when the cultivation is continued if it be an average and the fertile constituents are gradually wasted, for the same material (the upper two inches) is used over and over again and hence the poor crops. If the land is unusually rich in dormant plant constituents the fertility is maintained for a longer time.

This is not the case where the improved plough is used, it turns up more soil, four to six inches or more, and hence there is not only more feeding growth for the plants but a larger store of plant food to fall back upon; besides the depth of ploughing could be varied at different seasons.

Under any system, be it the ordinary wet cultivation, dry cultivation or the improved system, the land is found to get poorer year by year unless manure be added to it or unless it be fed by a silt-bearing stream. But one thing is clear; that is that a land worked according to the improved system would retain its fertility much longer than it would otherwise.

In this connection I may mention that the paddy soils of Ceylon have never been subjected to any series of chemical analyses, and it would be in the interest of the improvement of paddy cultivation if a series of samples of paddy soils be obtained from the different districts and subjected to a careful analysis.—Yours truly.

W. A. D. S.

THE ORIGIN OF "PADDY."

Ratnapura, Jan. 6th.

DEAR SIR,—I should be glad if you would inform me of the correct derivation of the word "paddy," as applied to grain grown in Ceylon.

2.—Is the word in use in other countries, and when was it first used in Ceylon?—Yours faithfully,

C. S. V.

THE PRICE OF PEKOE SOUCHONG.

Colombo, Jan. 8th.

DEAR SIR,—I have some difficulty in understanding the meaning of "Why" 's last letter, but at any rate he does not answer my statements.

With regard to what he says about the buying standard which I mentioned, why he should suppose instructions to buy tea of equal quality to a sample sent (as a standard) mean "buy quotable Pekos Souchong at 25 cents" (whatever that may mean) passes my comprehension, I understand it to mean buy tea to match the standard sent, not to match "quotable Pekoe Souchong," or else why send a standard?

But I will not waste more of your valuable space. I offered to buy tea of quality considerably below that of your standard, at more money than "Why" tells me it is selling at in Colombo; but though that is more than a month ago I have not had a single package offered me. This is I think sufficient answer.—Yours faithfully,

A BUYER.

RICE CULTIVATION; A PLEA FOR THE GOYIYAS AND THEIR HUSBANDRY.

Veyangoda, Jan. 8th.

DEAR SIR,—Please permit me to have my little say on what you and your correspondents have written on the above subject.

I must preface my remarks by observing that whatever the results obtained by Mr. Green and Agricultural Instructors, they have no practical bearing on the justice or otherwise of the paddy tax. All that they prove are the possibilities in the way of yield by the adoption of improved methods. These are not in general, and the yield of paddy cultivation is, except in favorable localities, what was represented to His Excellency during his travels. The question, therefore, resolves itself into whether the recovery or rather exaction of a tythe from fields whose average yield is 5 fold, is a cruel and grinding tax, or no. The Select Committee of the Legislative Council recommended, if I mistake not, the exemption of lands yielding less than 5 fold, and you have ever heartily endorsed their recommendations, therefore you must be of opinion that the continuance of this exaction from fields yielding these miserable returns is cruel, or at least unjust.*

Now to the editorial comments on the letter of "W. A. D. S." I do not think anything he has written warrants the conclusion that the small proportion of plants that results to the number of seeds sown is due, as you assert, to carelessness or worse in harvesting and preserving seed paddy. There is no branch of paddy cultivation operations to which the *goyiya* pays so great attention as the preparation and storage of seed paddy. But hardly one per cent of the *goyiyas* grows sufficient paddy to reserve for seed. The seed granaries belong to the minor headmen or to the extensive field owner, a very small proportion indeed of the village population. Where I reside I know only one man for a group of 5 or 6 villages, who is in a position to store and sell seed paddy. When his stock fails, I know people go as far as Hauratgoda to procure seed paddy. † It must

* With just this qualification, that the very exemption will be a premium on bad husbandry.—Ed. T. A.

† Then the quality of the seed depends upon one man here and there, and not to the care attributed to the *goyiyas* generally.—Ed. T. A.

surely be known to you that a certain proportion only of every kind of seed germinates. The proportion is not fixed and varies with circumstances. The *goyiya* makes allowance for that, as well as for what rots by becoming too deeply embedded in the mud,‡ for what is washed away by the rains and for what is eaten up by birds, when he sows the quantity he does per acre.

The system of paddy cultivation as practised by the natives may be unscientific, but it has not been so denounced by Hughes, Wallace or Voelcker—but no one with an intimate acquaintance with the preparation of fields will call it "careless" as you have done, nor is it correct to say that ploughing is a mere stirring of a few inches of water-saturated mud.

There is no doubt that one of the advantages of the iron plough is its ability to plough land when dry; but it neither pulverizes the soil nor stirs the subsoil without bringing it to the surface. In fact the complaint against it is that it leaves the land with large clods on the surface, which it is expensive to pulverize, and it brings to the surface sour subsoil.

I am very strongly of opinion that the increased yield resulting from the experiments of the Instructors, is due chiefly to the fields being ploughed at the beginning of the dry season and being exposed for a month or two to atmospheric influences. I think the introduction of a "cultivator" or subsoiler will yield better results, in mere scores than one, than those of the iron plough. It will be lighter than the plough, and therefore more suitable for village cattle. In appearance and action it will closely resemble the native plough, and it will work deeper than the iron plough, without bringing the subsoil to the surface.

A critic should be certain of his facts and not lay himself open to a charge of misrepresentation.† No one, as far as I am aware, cited Professor Wallace against dry and deep ploughing. He told me personally that he was no believer in the iron plough in paddy cultivation, that the native plough suited our special circumstances and that with a little improvement, which he promised to effect, it will be a very useful little implement. He also told me that the artificial aeration of the soil was not so necessary in a tropical land as in Europe, and that the innumerable fissures he saw in paddy fields did naturally what had to be done by an expensive process in Europe. He denounced neither deep nor dry ploughing in my hearing.

Dry cultivation of paddy has no doubt all the advantages enumerated by Mr. Elliott and more, but it struck me as a very slovenly system. The fields are not so carefully prepared as in wet cultivation, the beds are not smoothed nor the weeds got under the soil.

That the paddy soils of Ceylon have not been systematically analyzed is a reproach, that ought to be the aim of the School of Agriculture to remove.

The system hitherto practised of stationing an Instructor in a village for a few months and then removing him to another far removed from it, is I think a waste of public money and of valuable time and energy. We know that even with a progressive and enlightened people, no radical reforms can be made except their advantages are constantly demonstrated. In fact "pegging away" is necessary for all reforms. Can it be imagined that a conservative class like the *goyiyas* can be made to give up time-honored customs and take to revolutionary methods of paddy cultivation by Instructors flitting about the country? I lately advocated elsewhere the appointment of an Instructor to every Kerale, whose duty will be to establish experimental cultivation of high and low lands in connection with every village school. These stations to be under the immediate supervision of the school masters. Whether as a result of that or not I know not, but I was glad to hear the Director of Public Instruction at the recent prize-giving in connection with the

* Would not soil less in the condition of mud be better for the seed and also for the resulting crop?—Ed. T. A.

† This refers, of course, to our correspondent "W. A. D. S."—Ed. T. A.

School of Agriculture foreshadow a scheme for the larger employment of Instructors. The policy of maintaining a School of Agriculture and expecting that the educating of a few lads in it will benefit the masses through the percolation to them of the instruction afforded there, is as shortsighted as the restoration of gigantic irrigation works in uninhabited wastes without improving means of transport, so as to induce settlement under them and encourage the raising of paddy beyond the personal wants of cultivators. Both undertakings will not yield adequate returns to Government for the money expended.

My principal object in writing this letter is to attempt to remove from your mind, the conviction, which you say the perusal of the communication of "W. A. D. S." has left on it, that the small returns of paddy cultivation is more often due to "perfunctory husbandry" than to soil or to too much or too little water. I am sure your correspondent could not have intended to create in your mind an impression so damaging to his countrymen. I am not a blind admirer of the *goyiya*, nor do I believe him to be a model of industry; but this I do say, and say it with emphasis, that though his methods may be primitive and unscientific, yet they cannot, in connection with paddy cultivation, with truth be said to be "perfunctory." Surely, sir, you have seen and admired the care and skill with which he prepares his rice fields, in your frequent railway travels along the main line of railway.

[No doubt the mud is well worked and nicely smoothed; but query, if less water and more "elbow grease" would not result in greater returns of better grain?—Ed. T. A.]

CEYLON TEA SEED EXPORTED: GERMINATION RESULTS.

Jan. 12th.

DEAR "OBSERVER,"—I promised in my letter to you of 27th July to let you know the results of tea seed exported from Ceylon compared with that from Assam which has so much longer transport delay. As I said the seed I took with me to Java was only 10 days from my seed-bearers here (Ratnapura) to the *S'lands Plantentuin*, (Government Gardens) Buitenzorg. My advices from Batavia are:—"The long drought we have had has been very unfavourable to experimenting with new descriptions of seed, and planters' attention has been solely given to keeping their growing plants alive. The *Tjisalak* report on the outturn of the seed not yet received." Notwithstanding this unfavourable weather, &c., in a letter Dr. Trenb, the distinguished botanist in charge of the Government gardens, has favoured me with, he says:—"The seeds were sown (100 each) on 25th July. The young plants were counted today (3rd Nov.)

Lot A has produced 70 seedlings per 100

Lot B " " 78 " &c."

so I think I can safely guarantee 75 per cent plants for Java and say 80 for Singapore and the Straits Settlements generally; and shall do so in my next blazer* in your *Tropical Agriculturist* (Feb. 1892 number). My agents in Singapore (Messrs. Paterson, Simon & Co.) can do the same in the Straits newspapers.—Yours truly,

WILLIAM GRIGOR SANDISON.
Sana Estate, Ratnapura, Ceylon.

PROGRESS OF BRITISH NORTH BORNEO.—Mr. Henry Walker writes to us:—"North Borneo is going ahead and I am glad to say attention is being paid to many new products. The Government is stimulating the cultivation of gambier which has shown itself to be well adapted to our climate and of pepper by offering rewards for the cultivation and proper up-

* Blazo away!—Ed. T. A.

keep of certain fixed areas, and cotton also has been introduced, the small sample so far obtained being remarkably fine and strong. Coconuts and fruit are also receiving attention. Those of your planters who are nervous and cannot meet the fluctuations of the tea market calmly, should come here and see our Liberian coffee—it would do their hearts good to see it."

FOODS THAT BENEFIT THE SOIL.—Of all foods procured off the farm and fed to stock, cotton seed meal possesses the highest manurial value, as a ton of cotton seed meal contains 135 pounds of nitrogen, 30 pounds of phosphoric acid, 56 pounds of potash, bran containing 80 pounds of nitrogen, 28 pounds of phosphoric acid, and 51 pounds of potash. These substances are the most evenly balanced of all foods that enrich the land, and the farm will suffer but little loss if they are used as a portion of the ration for the stock. The farmer can, by noting the effects of certain crops on the soils, and growing such crops as may be best adapted thereto, with judgment in the selection of his stock foods, return to the soil all that the heaviest yield of any crop may carry away from the farm.—*Exchange*.

THE COFFEE PRODUCTION OF BRAZIL.—According to a recent bulletin of the Bureau of the American Republics in Washington, the coffee plant was imported to Brazil from Africa, and found there the conditions necessary for a marvellous growth. In 1800 Brazil exported 13 bags of coffee; in 1817, 66,986 bags; in 1820, 97,498; in 1830, 481,222; in 1840, 1,037,981; in 1876 3,765,122. The annual production now is about 6,000,000 bags of 132 lb. each. The United States takes as much Brazilian coffee as all Europe. For its cultivation virgin forest lands on hill sides are preferred, as it is known that extreme heat and cold are unfavourable to the growth of the plant. In four years the plant begins to produce, and from that time forward the production continually increases. The tree attains the average height of about 10ft., and its head a diameter of 5ft. It reaches its *maximum* productiveness at about nine years of age, and continues in bearing for 40 years if carefully pruned. There are three annual bloomings and corresponding crops of which one is vastly more important than the others. The coffee is gathered in baskets and carried to yards of hard beaten clay, where it is dried in the sun, or in drying pans by artificial heat. The outer shell is separated from the beans by machinery and the thin, inner husk by other machines, and the coffee is then ready for market. Its quality is greatly improved by age, the aroma increasing as desiccation goes on. The best Brazilian coffee when dried is usually of a pale colour, while the new immature beans are green. The different varieties possess different qualities, though from the same crop are obtained Mocha, Java, and other varieties that figure in the market reports. The beans of different sizes and weights are separated by machinery, and sold as Mocha, Java, &c., according to the taste or gullibility of the consumer. For those who do not know that a green colour is usually an evidence of immaturity the light and spotted beans are dyed to a beautiful green, which is easily washed off in warm water, as it should be before using. It is probable that not a ton of true Mocha enters the United States annually; but thousands of pounds of Brazilian "pea-herry" are sold every month in the New York market as genuine Mocha. The characteristic constituent of coffee is caffeine, whose chemical formula is identical with that of theine; of theobromine of cocoa, and of guaranine.—*London Times*, Dec. 26.

CATERPILLARS ON ALBIZZIAS.—A box of poor tea attached to a branch of albizzia having been sent to me by a planter who wished to know if the insects were likely to do harm, we handed them to our entomological referee, who writes:—"The poohies are the larvae and cbyrealids of a common little yellow butterfly belonging to the genus 'Terias.' They feed on a great variety of plants, but are not likely to do any more than temporum damage to the plant they select. When noticed they can be collected by hand and destroyed."

PREPARED COFFEE LEAVES.—Coffee-tea was brought under the notice of the Royal Botanic Society of London on Saturday at a meeting presided over by Mr. G. J. Symons, F.R.S. The samples of coffee-tea, or prepared coffee leaves, were grown in the Society's Conservatory. The secretary said it had been estimated that the percentage of theine in the leaves of coffee was 1.20 as against 1.00 in the beans. As the leaves may be easily grown in many parts of the world where it is difficult to insure good crops of coffee beans, he thought it might prove a valuable agricultural product in many of our warmer colonies. At present, he said, only some 2,000,000 men use coffee-tea in comparison with 110,000,000 who use the bean, and 500,000,000 who drink Chinese and Indian tea.—*Echo.*

CYLON TEA IN AUSTRALIA.—We have been naturally gratified by the receipt of a note from a Ceylon planter who has returned from a visit to Australia, in which he is good enough to say, after conveying remembrances from old friends,—

"Till I visited Melbourne I did not realise how much good you have done the Ceylon Tea industry." The period referred to, 1880-81, is an age back in the history of the rapid rise and progress of the tea enterprise. It was the day of small things, but of large promise; and few can imagine the virulence of the attacks we had to bear from vested interests in China tea, and the hardness of the battle we had to fight in common with our friend, Mr. James Ioglis, who represented India in the absence of Mr. (now Sir Edward) Buck, to secure fair play for the teas of India and Ceylon, which were being introduced to the Melbourne market. We were fortunate enough to get Mr. Newbery, O.M.S., of the Melbourne Museum, and his Assistant Chemist and Mr. Moody of Messrs. Henty & Co., interested in our Ceylon products; and the results of a number of elaborate analyses by the able Government chemists, went to show what Mr. Gosehen recently dwelt on, the superior cheapness of our tea in comparison with that of China, when strength was considered. We were also able to exercise some influence through the Melbourne press which helped the then infant cause. But the contest was a hard one. It is pleasing to learn that, though largely forgotten here, friends in Melbourne appreciate the efforts we made and have conveyed their impressions to a Ceylon planter after the fashion he kindly indicates.

A BARK SYNDICATE AT WORK.—A syndicate of bark importers, formed for the purpose of keeping up the price of cinchona bark, commenced its operations at last Thursday's bark sales in Amsterdam. At those auctions 470,441 kilos. of manufacturing bark (containing about 20,000 kilos. quinine) were offered. Of this supply, 30,000 kilos. bark, representing 1,453 kilos. quinine, were bought in, leaving 490,069 kilos. bark (=18,548 kilos. quinine) as the total purchase by the various competitors. The syndicate purchased over one-fourth of this quantity—viz., 118,441 kilos. bark, equal to 5,136 kilos. quinine sulphate. This quantity, it should be borne in mind, has not

gone into consumption, but is at present stored up. The primary object of the combination is said to be the advance of the unit to 7s., or 1½d. per lb., and it is believed that funds to the extent of 500,000fl. (nearly 42,000) are at its disposal for the realisation of this object. The total cost of the bark purchased at Thursday's auctions by the syndicate was 60,000fl.; or 5,000l. If, therefore, the combination continues its operations, in Amsterdam only, upon the same scale at succeeding auctions, its funds will be exhausted at the end of August next year, and it will then, upon the basis of the present price, have accumulated about 950,000 kilos. bark. At the preceding Amsterdam auctions the unit averaged 5 83s. Since then quinine has fallen 10 per cent in value, and, calculating upon that basis, an average unit of 5'2s. would have been the true market level. On Thursday last, as a matter of fact the average rose to 5'65s.; hence the prohasere who bought for actual consumption had to pay an average of 0.80c. per kilo., or about 7.16d. per lb. more for their quinine than they would presumably have paid had the market been allowed to follow its natural course. As the manufacturers bought bark representing about 13,000 kilos. quinine, it follows that the syndicate by expending 60,000fl. (5,000), compelled the makers to an extra outlay of about 10,700 fl. (900l.)—*Chemist and Druggist*, Dec. 26th.

EXOTIC TREES AT SAHARUNPORE, N. W. P., INDIA.—From the interesting and comprehensive report of these Gardens, which are extra-tropical and in a region of moderate rainfall, we extract as follows:—

The following is a statement showing the number and kinds of trees under trial in the exotic plantation and their present condition:—

Name.	Number planted out.	Remarks.
<i>Acacia rupestris</i> ..	4	Healthy, but growing slowly.
Do. <i>tortuosa</i> ..	6	Doing well.
<i>Anogeissus pondula</i> ..	4	Healthy, but growing slowly.
<i>Acer dasycarpum</i> ..	4	Not doing well.
<i>Brossonnetia payprifera</i> ..	27	Doing well.
<i>Cedrela australis</i> ..	3	do.
<i>Oroton tiglinum</i> ..	3	Healthy, but growing slowly.
<i>Ceratonia siliqua</i> ..	34	Healthy; fruits freely every year.
<i>Divi Divi</i> ..	5	Not doing well; out down every season by frost.
<i>Diospyros virginiana</i> ..	2	Healthy, but growing slowly.
<i>Eucalyptus meliodora</i> ..	10	Doing well.
Do. <i>oitriodora</i> ..	13	do.
Do. <i>sp</i> ..	10	do.
Do. <i>saligne</i> ..	15	Doing best of all.
Do. <i>bicolor</i> ..	3	Growing slowly.
Do. <i>robusta</i> ..	46	Doing well.
Do. <i>resinifera</i> ..	15	do.
Do. <i>rostrata</i> ..	380	do.
<i>Melia sempervirens</i> ..	15	Doing well and growing fast.
<i>Pithecolobium bigeminum</i> ..	12	Doing well.
<i>Catalpa bignonioides</i> ..	20	Growing slowly; not very healthy.
<i>Owenia cerasifera</i> ..	7	Doing well.
<i>Prosopis spioigera</i> ..	14	Growing slowly, but healthy.
Do. <i>juliflora</i> ..	100	Doing very well; makes a good rough hedge.
<i>Swietenia macrophylla</i> ..	4	Growing slowly.
Do. <i>mahogan</i> ..	7	Doing fairly well.
<i>Sesium liglandulosum</i> ..	4	Injured by frost; does not seem hardy.

CROPS OF CEYLON TEA SINCE 1883:
ANNUAL INCREASES AND YEARLY
PERCENTAGES OF INCREASE.

A mistake having crept into our article on crops past, present and future, whereby the increase of 1891 over 1890 was understated by a couple of millions of pounds, we now give figures for crops, with absolute increases of succeeding years and percentage of increase in each case since 1883, when, for the first time, our export exceeded a million of pounds:—

YEARS.	Crops lb.	IN- CREASES.	PERCENTAGES OF INCREASE.
1883 -	1,665,000	—	—
1884 -	2,393,000	728,000	43 $\frac{1}{2}$
1885 -	4,373,000	1,980,000	82 $\frac{1}{2}$
1886 -	7,850,000	3,477,000	79 $\frac{1}{2}$
1887 -	13,834,000	5,984,000	76
1888 -	23,821,000	9,987,000	72
1889 -	34,346,000	10,525,000	44
1890 -	45,800,000	11,454,000	33 $\frac{1}{2}$
1891 -	67,000,000	21,200,000	46 $\frac{1}{2}$
1892*	85,000,000	18,000,000	26 $\frac{1}{2}$
1893*	100,000,000	15,000,000	17 $\frac{1}{2}$

Our readers will see from the above figures that in the third year of the series the increase over the previous year was actually 82 $\frac{1}{2}$ per cent. The rate of increase per cent then went gradually down until that of 1890 over 1889 was 33 $\frac{1}{2}$, a rise of just one-third. Then came the year of exceptional weather and exceptional yield, 1891, when the percentage of increase approximated 50, the exact figure being 46 $\frac{1}{2}$. Our estimate for 1892 of 85 millions of pounds is lower by 20 per cent than this rate, and lower by 7 $\frac{1}{2}$ per cent than the rate for the normal year 1890 over the normal year 1889. Our estimate for 1893, high as it seems, is only at the rate of 17 $\frac{1}{2}$ per cent, or only a little more than one-half the lowest percentage of increase previously shown. We fear, therefore, in view of all the circumstances, especially in view of the fact, that the whole 250,000 acres, including the 66,000 planted subsequently to July 1888, will then be as nearly as possible in full bearing, at the average rate of 400 lb. per acre,—we fear our estimates are only too likely to be realized. As we have said already the general adoption of light plucking might lessen our figures, and we believe that in a good many cases the order for lighter plucking has gone forth. But we have more confidence in the Chicago crusade and similar efforts in regard to other markets, than belief in the general adoption of plucking so light as materially to effect the yields we feel compelled to estimate.

THE DUTY ON TEA.

A FALLACY TO REPRESENT THAT ITS REMISSION WILL BENEFIT THE WORKING MAN.
(By W. F. PONDER.)

When the Colonial Treasurer announced to the House and to the country with a flourish of trumpets, and as a preface to announcing his general taxation policy, that it was the intention of the Government "to take the duty off the poor man's tea," it was but too plainly evident that this course was adopted with the sole object of attracting the public mind from the enormity of the proposals that were to follow, and blinding them to the serious weight of the burdens it was their intention to bind upon them.

"A free breakfast table at last," interjected the member for Bourke, Mr. Willis; an old Gladstonian cry of 30 years ago, that was doubtless intended should be taken up by the populace and echoed throughout the country. "A free breakfast table," forsooth,

with a duty on bread and butter, sugar and milk, coffee, crockery, cutlery, and every other requirement that makes the distinction between our educated civilization and savage ignorance. And thus, this protectionist Government wishes to pose as the "poor man's" friend, the champions of the working man, and make a party cry of the fact that they have abolished the duty on tea, and thereby try to blind the public to the far greater fact that they will have to pay a much higher price for all the actual necessaries of everybody life, and that they are to be prohibited from enjoying any of its comforts unless they are prepared to pay the high prices that will result from the heavy duties placed upon what they characterize as "the rich man's luxuries."

But what does this great boon that it is proposed to confer upon the "poor man" really mean? Is Mr. See so ignorant of the commercial conditions under which the trade of the colony is carried on that he really believes the actual consumer will be benefited by it in the slightest degree?

In point of fact, instead of the remission of the duty upon Tea being a benefit to general consumers it will not benefit them in the least, but will simply confer a great benefit upon the rich importers and wholesale grocers who distribute this article of everyday consumption, and will leave in their pockets the sum of £110,000 annually that they have now to pay as duty before the Tea is released from bond, and which under present circumstances is one of the fairest sources of indirect taxation for providing the necessary revenue for state expenditure that exists.

To show that such is the case we have simply to look at the conditions under which tea is distributed to the public. In the first place it must be admitted that the general purchaser is totally ignorant of the actual value of the tea they buy. They may know the class of tea they like when they have it infused in the cup, but this is simply the result of education of the palate. They like a certain class of tea because they are accustomed to drink that quality, and this education goes to the extent of their often preferring a common inferior quality tea to a higher class and richer flavoured one, or to the class of blended tea supplied by one grocer in preference to that supplied by another, although the rejected sample may be worth from 6d to 1s per lb. more than the one that the buyer likes, simply through his having acquired a taste for the inferior article through constantly using it. This fact is taken advantage of by the general grocer, who always looks to get a large profit upon his tea. He may have to give the best value in sugar, an article the quality of which anyone can judge. He may have to cut down the price of his butter, cheese, bacon, jams, and other standard goods to the finest margin to compete with his opponents, but he must make up for this by getting a large profit on his tea, because in this his customers cannot judge of the relative values offered, being in total ignorance of the value of the article they are purchasing.

The truth of this statement is evidenced by the fact that numerous grocers advertise and proclaim by large signs that "they will give 5 lb. of the best white sugar to each purchaser of 1 lb. of their best 2s tea." "Now let any thinking mind analyse this wonderful offer; do they really imagine that they will get 1 lb. of the best 2s tea," and that the kind-hearted grocer generously presents them with 5 lb white sugar? If they do, let us inform them for their information that it is much more probable that they get 1 lb. old exhausted rubbish, that once perhaps deserved the name of tea, and that would be now dear at any price, and that by this catch the grocer makes a profit on his sugar that otherwise he would not get. The working man can now buy his tea at any price, from 1s per lb. upwards, according to his taste and requirements. Let us ask him to use his own common sense and practical knowledge of the world, and say whether in the face of the foregoing facts it is at all probable that he would be able to buy his tea cheaper, or get better value for his money through the fact of the 3d per lb. duty being taken off. We can tell him he will not. The remission of the

* Estimates.

duty will simply enrich the importer and the grocer, who will thus be able to increase their already large profits while the Government are using the fact as an excuse for putting heavy duties upon every other article he consumes.

But there is another and most serious view that has to be taken of the results that are likely to be brought about if this proposed remission of duty is carried into effect, and one that will make even the Government pause and consider before they finally adopt this policy. It is a well-known fact, and one that has been repeatedly brought before the community in the public press, that tea is most liable to adulteration, and that the Chinaman loses no opportunity of foisting an inferior and adulterated article upon any one that will allow him. To such an extent has this been done in the past that in England, where a special law has been passed authorising confiscation, whole cargoes have often been destroyed to prevent them going into consumption. In Victoria and Queensland, where specially qualified officers have been appointed to prevent the introduction of inferior quality and adulterated tea, shipments are often condemned and prevented from entering the ports. But here in New South Wales no such precautions have been taken. The only protection that exists is the fact that teas imported are under Customs House supervision, and are sampled and weighed by the Custom authorities. Take away this solitary though slight guarantee by exempting tea from the payment of duties and Customs control, and we give a premium to the Chinaman to make this colony a receptacle, for all the filth and rubbish they can produce, the only act that exists against a falsification being absolutely inoperative, as its wording precludes the possibility of interfering with anything that does not actually endanger human life.

Such being the actual position in which the Government proposal places the general public, it remains for the so-called "poor working man" and the consumer generally to judge the amount of kudos they are entitled to for proposing to remit the sum of £110,000 duty upon tea and place an extra duty of £336,000 upon all the ordinary requirements of everyday life.—Sydney Evening News.

CEYLON TEA AVERAGES IN LONDON FOR 1891.

As the last public sale of Ceylon tea for 1891 has been held in London, we give below in tabular form the results of Reuter's and Messrs. Wilson, Smitbett & Co's telegrams received by us weekly during the last twelve months, with similar figures for the previous year, for the sake of effective comparison. There has not been very much fluctuation in the figures for the weekly average; and the monthly figures show even less movement. The latter were as follows:—

	MONTHLY AVERAGES DURING 1890 AND 1891.		1890		1891	
	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.
January	... 0 11½	0 11½	July	... 0 10½	0 9	
February	... 0 10½	1 00	August	... 0 10½	0 9	
March	... 0 10½	0 10½	Sept.	... 0 11½	0 9½	
April	... 0 10½	0 10½	Oct.	... 0 11½	0 10	
May	... 0 10	0 9½	Nov.	... 0 11½	0 9½	
June	... 0 10½	0 9½	Dec.	... 0 11	0 10	

Prices during the early part of this year were higher, and in the latter lower, than was the case last year.

[The above from the local "Times" under- rates, we submit, the fall in prices in 1891. In 1890 the prices never went below a monthly average of 10½d. In 1891, the prices for the first four months ranged at 11½, once reaching 1s. Then came a drop to below 10d for 5 months, the figures for July and August being only 9d. October showed 10½, November 9½d, with a recovery to 10d in December. The record of 1891 is that of the lowest prices ever realized for Ceylon tea, the redeeming feature being the ultimate good effects, which we may take to be certain, of the large quantity consumed.—Ed. T. A.]

THE ORIGIN OF "PADDY."

In reply to the first question put by our correspondent "C. S. V." elsewhere, we would quote the following from Yule's "Hobson-Jobson".—

Paddy, s. Rice in the husk; but the word is also, at least in composition, applied to growing rice. The word appears to have, in some measure, a double origin. There is a word *batty* used by some writers on the west coast of India, which has probably helped to propagate our uses of *paddy*. This seems to be the Canarese *battu* or *bhatta*, 'rice in the husk,' which is also found in Mahratti as *bhat* with the same sense, a word again which in Hind. is applied to 'cooked rice.' The last meaning is that of Sansk. *bhakta*, which is perhaps the original of all these forms. But in Malay *padi*, Javan. *pari*, is 'rice in the straw.' And the direct parentage of the word in India is thus apparently due to the Archipelago; arising probably out of the old importance of the export trade of rice from Java (see *Raffles's Java*, i. 230-240, and *Crawford's Hist.*, iii. 345, and *Descript. Dict.* 368). *Crawford (Journ. Ind. Arch.*, iv. 187) seems to think that the Malayo-Javanese word may have come from India with the Portuguese. But this is improbable, for as he himself has shown (*Desc. Dict.*, u. s.), the word *pari*, more or less modified, exists in all the chief tongues of the Archipelago, and even in Madagascar, the connexion of which last with the Malay regions certainly was long prior to the arrival of the Portuguese.

It will be seen from the above that the origin of the word "paddy" is somewhat uncertain. With regard to the second question (or rather questions): (a) The word "paddy" is used generally throughout the east by English-speaking persons. (b) This is a more difficult question to answer. There is no doubt that the word was introduced into Ceylon by the English. The Dutch invariably used the Tamil word *nelli* for rice in the husk, following the example of the Portuguese in this. Vieyra's Portuguese-English Dictionary has "*nelle*, rice that has not been peeled." The word is still current in the Ceylon Portuguese. Knox does not mention the word "paddy" at all; and the first writer on Ceylon that we know of who uses the word is Pybus, who in the account of his mission to the King of Kandy in 1762 speaks of "paddy plantations." Hugh Boyd in the journal of his embassy to Kandy twenty years later also mentions "paddy." Percival writing at the beginning of this century says: "What is commonly called *paddy* is a very inferior grain." Gordiner writes "paddee." From the first of the following quotations given by Yule, it will be seen that the word was first brought to England from Java in the 16th century:—

1580. "Cortaine Wordes of the naturall language of Jana . . . *Parce*, ryce in the huske."—*Sir F. Drake's Voyage*, in Hakl., iv. 246.

1598. "There are also divers other kinds of Rice, of a lesse price, and slighter than the other Ryce, and is called *Batte* . . ."—*Linschoten*, 70.

1600. "In the fields is such a quantity of rico, which they call *bate*, that it gives its name to the kingdom of Calon, which is called on that account *Batecalou*."—*Lucena, Vida do Padre P. Xavier*, 121.

1615. ". . . oryzæ quoquo agri feraces quam *Batum incolæ dicunt*."—*Jarric, Thesaurus*, i. 461.

1673. "The Ground between this and the great Breach is well ploughed, and bears good *Batty*."—*Fryer*, 67, see also 125. But in the Index he has *Paddy*.

1798. "The *paddee* which is the name given to the rice, whilst in the husk, does not grow . . . in compact ears, but like oats, in loose spikes."—*Stavornius*, tr. i. 231.

Wilcocke, the translator of Stavornius, adds the following note to the passage quoted above (the author is speaking of Java):—

The following, besides many others, are names applied to rice, in its different stages of growth and preparation: *paddee*, original name of the seed; *oossay*, grain of last season; *hancee*, the rice-plants before transplantation; *bras*, or *bray*, rice stripped of its husk; *charroop*, rice cleaned for boiling; *nassce*, boiled rice, &c.

If any reader can give us a reference to paddy by any writer on Ceylon earlier than those we have referred to we shall be obliged.

THE FISH LEAF.

As no one has answered my questions: (1) the meaning and derivation of this name, (2) the cause, or nature, of this "abortive leaf," I will say what I think about it myself. Standing before a recently pruned tree the other day it occurred to me for the first time to give myself a scientific lesson in the growth of the flush, and, consequently, in "plucking." This proved to be as simple as it was interesting, and, in an instant, to make the whole art of "plucking" as clear as till then it had been obscure, and followed only by rule of thumb. But, as in many other things, this useful rule is often a very safe one, as witness the absolutely perfect practice carried on by most Ceylon planters.

First, then, what is the "fish-leaf"? Anyone who will take the trouble to examine a new "shoot"—whether upon a newly-pruned branch, or from the flushing wood of a tree ready for the knife—it will be seen that the bud itself being too tender to pierce the bark or skin of its parent stem, nature has provided a stronger and coarser gimlet for this purpose. This gimlet is, in fact, a hollow case composed of two sides, and when once through resolves itself in a smooth orifice, or matrix for the passage of the new shoot. Once born into the light, the shoot or flush, grows without further aid, each bud in turn developing itself into a true leaf. In the case of the tea plant this case, or matrix, or vagina, does not wither and fall off, but attaches itself to the root of the new shoot, which carries its birthcase with it, and thus forms two abortive leaves. One (the smallest side not always developed) simply curls round near the root of the shoot like a tiny whitish fin, while the other side of the case (the true fish leaf) is carried further up the shoot and assumes more the appearance of a true leaf. I need not moralize on what this teaches in regard to plucking, as that is self-evident. To duly nourish a new shoot thus formed, either a full flow of sap is necessary, as in the case of new growth from bare old wood, or a matured leaf on greener wood, to feed the new shoot growing under its protection.

Now as to the first question, viz., the name "fish leaf"? All planters know that this is called by the coolies "Toppil Elei," but not many know that being translated this means the "Navel" leaf, the "navel" of each new shoot. Now this name in its absolute correctness is highly scientific, so much so as to be amazing, and I for one should very much like to know whence it came. We are apt to look upon our humble workers as the opposite of observant and scientific, and yet here is a name in common use amongst them more scientific than anything we have invented for the same purpose. Not that Ramasamy and Minately ever think of its real signification unless their attention is called to it, so far even as the more name is concerned, and of course all are ignorant alike of the facts above given. Still there is this proper and curious name in every-day use, and what I ask is, whence came it?

And now I come to its designation by the European planters, viz. "fish-leaf"! Why "fish-leaf"? This seems a poser, and though I am going to give a good guess (so far as Tamil is concerned), I do not overlook two important considerations; first, that a closer acquaintance with the science of botany than I possess may furnish an answer to this question, and second, that—if the name originated in Assam—Tamil could have had nothing to do with it, though it may be, for all that I know to the contrary, that the coincidence of language may even then ac-

count for it. Well, then, I do not think it is called the "fish-leaf," because it bears much resemblance to a fish—though the smaller half of it does look finnish. We have already seen that Tamil is not to be despised as an authority, and, if the term had originated here, I should say "fish-leaf" was nothing but a corrupt English rendering of *Mün elei*, or first, fore, front, preceding, advance leaf. Either of these words will render *Mün* (going before) in English, and also correctly describe the growth and position of the "fish-leaf." But, query, how do we get "fish" out of "mün"? Answer, by the corruption I have already hinted at—"mün," with a *u* sound, is by Europeans nearly always called *min*, and whereas "MÜN" means first, or before, "MIN" means fish! R. W. J.

[NOTE BY KÁROLY FIINDÖ.—The above learned discourse on the "Fish-leaf" is full of most interesting and enjoyable reading, and will no doubt lead us all to study with greater pleasure and profit the life-history of our fish. But I must take exception to the derivation of the Tamil name "min elei" from *min*, before: for the *i* of *min* is long (as the very name *Minádebi*, fish-eyed, quoted by R. W. J., proves), though derived from a root *min*, to shine, from which come *minnini puchchi*, a glow-worm, and *minnal*, lightning. The Tamils call stars *van min*, the sky fish, and when the sky is spangled with them they say the stars *minnichirathu*, are in shoals! That the germ-leaf is like a fish both in shape and colour I never heard anyone before deny: but it should seldom, if ever, be allowed to come to the scales. *Thoppul elei*, navel leaf, is certainly extraordinarily scientific, and it would be worth while finding out what the North Indian labourers call it.]

Some interesting statistics of agriculture have recently been published, from which it appears that the largest natural hive in the world is the mammoth cave of Kentucky, which has been taken possession of by myriads of bees. The great bee-master is Mr. Harbison, of California, who owns 6,000 hives. In Greece there are 30,000 hives, in Denmark 90,000, in Russia 110,000, in Belgium 200,000, in Holland 240,000, in France 950,000, in Germany 1,450,000, in Austria 1,550,000, and in the United States 2,800,000 hives. It is calculated that a bee sucks 218,750 flowers for every ounce of honey.—*Globe*.

THE DELIVERIES OF CEYLON TEA IN LONDON for 11 months ended November were, in 1889 28,443,000 lb.; in 1890 34,880,000 lb., an increase of 6,337,000 lb.; in 1891 49,362,000 lb., an excess over the previous year of no less than 14,482,000 lb. This was, no doubt, largely the result of low prices; but the prices of Indian were also low without leading to a proportionate increase, while in China there has been a large decrease. With due care in preparation, there seems no fear that Ceylon will preserve its leading position in the markets. The deliveries of our teas for 1891 in London must have been about 53½ millions of lb.; and counting exports to Australia and other places direct the world's consumption of Ceylon tea must have been 57 millions of lb.

THE RICE CROP IN BURMA.—The report received from the local administration on the prospects of the crop on 31st December is as follows:—"The area under paddy cultivation in the ten chief rice-producing districts of Lower Burma is now estimated at 4,107,562 acres, or 191,374 acres more than the actuals of last year and 34,222 acres less than the area reported last month. The areas reported from Akyah and Shwegyin are unchanged, while the small decreases in Hanthawaddy, Tharawaddy, Prome, Bassein, Henzada, and Amherst. Pegu reports a further decrease of 16,453 acres due to destruction by floods. The crop estimates are the same as last month excepted in the case of Tharawaddy where a sixteen-anna crop is now expected. It is estimated that there will be available for export 1,215,500 tons of cargo rice, equivalent to 20,601,690 cwt. of cleaned rice, including what is required for Upper Burma."

THE COMMERCE OF CEYLON
FOR 1891.

The EXPORT TRADE of Ceylon during the year 1891 compares very favourably as regards the chief articles of export with that of the two preceding years, indicating a further advance towards the condition of prosperity that prevailed during the period when coffee cultivation was flourishing and formed the chief staple export of the island.

The revenues of the country show a satisfactory increase as compared with past years; and it is probable that the prosperity of the island generally rests at the present moment on a more assured and substantial basis than has existed at any time during the past decade.

The danger that appears to threaten in the future is the over-production of TEA, which now forms our chief article of export, and upon the cultivation of which the revenues of the country directly and indirectly to a very great extent depend. When it is considered that the export has increased from .. 34,048,085 lb. in 1889 to .. 46,911,551 lb. in 1890 and .. 68,274,420 lb. in 1891

with probable further increase to .. 85,000,000 lb. in 1892 it is obvious that unless the consumption of Ceylon tea increases largely so as to compensate for the increased production a range of such low prices may be looked for as will serve to largely neutralize the benefits that might be expected to occur from the larger exports and in some cases render the cultivation of tea altogether unprofitable.

The tea planters and merchants of Ceylon are by no means oblivious of this danger; and strenuous efforts are being made in various directions to introduce Ceylon tea into countries where it is either not known or where the consumption is so small as to afford room for increase. A large measure of success has so far attended the efforts made with this end in view, and it is hoped that the opportunity afforded by the *Chicago Exhibition of advertising Ceylon tea* will result in a greatly increased consumption in Canada and the United States of America and the creation of a demand for our product in the Central and South American States. The colonies of Australasia took in 1891 3,210,598 lb. against 2,559,901 lb. in 1890 and Ceylon tea is becoming known in various parts of the world from Teheran in Persia to Samoa in Polynesia, and Tobago in the West Indies to Algeria in the Mediterranean.

Next to the marked increase in the exports of tea, the most noticeable feature in the export list is the greatly decreased export of CINCHONA BARK—the quantity sent away being only 5,679,339 lb. in 1891 against 8,728,836 lb. in 1890 and 14,838,402 lb. in 1886 when the cultivation was at its maximum.

The growing of this drug now attracts but little attention; and seeing that the unit of quinine has fallen in price, from 25 cents in 1885 to 6 cents, the present price in the local market, it is perhaps not to be regretted that a cultivation subject to such fluctuation, and of so precarious a nature, has fallen into desuetude.

The exports of COFFEE for the last three years have remained almost stationary at about 87,000 cwt.; and it appears probable that the export will average about this quantity for some years to come. The shipments now to a great extent form the yield of estates situated in districts where climatic conditions and superior soil have enabled the trees to resist to some extent the ravages of the coffee

leaf fungus, the cultivation of these properties being still profitable, notwithstanding a greatly reduced yield per acre.

The yield of CACAO has to some extent increased; the exports being 20,532 cwt. in 1891 against 15,981 cwt. in 1890 and 19,054 cwt. in 1889

The difficulties attending the cultivation of CACAO in large plantations lessen the probability of the exports increasing largely in the future. The cultivation of CACAO in village gardens appears however to be increasing, if the numerous small parcels brought to market by native dealers may be taken as an indication of this development.

The increased exports of CINNAMON and COCONUT OIL are probably due more to a favourable season than to a development of cultivation; and as regards the latter item to a decrease in the quantity of copra exported for manufacture into oil in other countries. The disastrous famine in Russia has affected the exports of copra to that country, the shipments that usually take place in September and October not having this year gone forward.

A new and interesting item of export appearing in the export list of the Ceylon Chamber of Commerce is DESICATED COCONUT, the manufacture of which—and other products derived from nuts—affords employment to a large number of labourers is both male and female in Colombo and elsewhere. Formerly the nuts were exported intact for manufacture at the port of delivery; but the superior quality of the shredded and desiccated kernel obtained from the nuts in a fresh condition has led to the development of a local industry that has already assumed some importance. Concurrently with the shipment of the desiccated nut the export of COCONUTS has fallen off from 11,907,969 in 1890 to 6,699,403 in 1891.

THE IMPORT TRADE of Ceylon during 1891 has not been exceptionally active or profitable, but the business has been done on a less unstable basis than during the preceding year, the violent fluctuation in exchange which took place in 1890, and which caused the import trade to be attended with a maximum of risk, not having been repeated in 1891. The sterling equivalent of the rupee during the year has averaged about 1s 5d, while in 1890 it fluctuated between 1s 5½d and 1s 9½d.

PLANTING SUMMARY OF 1891;
WITH ROUGH FORECASTS FOR 1892.

TEA.—An increase of over 22,000,000 lb. in our exports in one year is calculated to throw over us the shadow of the cloud of over-production. Still there are two or three very good reasons why the producer should lay before the consumer his belief that Ceylon tea in 1892 will only run about 75,000,000 lb.

First and foremost, that there is no such large increase of land coming from partial into full bearing or from unproductiveness to partial bearing.

Second, that it is very unlikely we shall have a season in 1892 such as we had in 1891, especially in the first 6 months of the year. In 1891, 13,000,000 lb. of the 22,000,000 lb. increase were shipped in that period.

Third, we are plucking finer. On one large estate the manager, working on the lines of 1891, estimated 240,000 lb. in 1892. He received instructions to pluck finer and only to estimate 200,000 lb. Another large estate in the lowcountry manufactured 250,000 lb. 1891. It is only estimated to give the same quantity in 1892.

The estates everywhere look in good heart. The

Indian tea man need not hug the delusion prevalent among the planting community there that our production is only a flash in the pan. As for our China friends, they "are not in it," Sir Andrew Clark to the contrary. Improved machinery and withering accommodation are everywhere being placed or provided in our tea factories; so that we shall not have such terribly low averages as we had in 1891.

LABOUR, which at one time was so scarce (in the beginning of 1891), is now more abundant.

COFFEE for the last 3 years has been exported up to 80,000 cwt. It will probably run down to 70,000 in 1893. The coffee in fields of tea over 3 years old has no chance.

CINCHONA went down 3,000,000 lb. in 1891, and for all it brings to the owners in the way of cash, it might cease to be an article of export. No one is doing anything in the way of planting fresh supplies, excepting, perhaps, a few plants of *Ledgeriana*.

COCAO has jumped up 5,000 cwt. in 1891 over 1890, and it may run up another 5,000 cwt. in 1892, as judicious shade is being cultivated and fields that were previously barren are now yielding 1 cwt. to 2 cwt. per acre. Continued wet weather has done harm to the fruit-bearing in the last half of the year, but moisture in the long run must tell on this product for good.

TOBACCO.—The less said about this product the better. It has been a regular "will o' the wisp."

CANNAMOM is not a general cultivation, being mostly confined to the dwellers in Rangala and Madamahannwara.

TIMBER cultivation has received great attention in 1891, and the fruits of it will be seen in a year or two in the improved appearance it will give tea estates, compared to what coffee estates presented.

THE CEYLON FOREST DEPARTMENT.

The following brief notes will give an idea of some of the operations in which this department has been engaged during the past year:—

(1) Surveys of forest by the Survey Department have been made, confined chiefly to the fuel reserves near Mirigama, the forests near Battuloya, North-Western Province, and the Kaligala forest in the Kurunegala district, North-Western Province, &c.

(2) Reservations of forests and village forests have been published in the *Government Gazette*.

(3) Forest Ordinance.—The draft of the amended forest ordinance only requires one more reading in Council. The chief feature is that the Government may place the Conservator in direct charge of reserved forests.

(4) Plantations.—(a) Railway fuel plantations at Galboda about 300 acres:—*Grevillea*, *eucalyptus robusta*, *pithecolobium dulce*, *ptorocarpus indicus*, *hal, hora*, *pithecolobium saman*, &c.

(b) Strip plantations at Nanuoya planted with blue gum, *eucalyptus robusta* and others, *acacia melanoxylon* and *decurrens*, some *cryptomeria japonica* and *pinus longifolia*.

(c) Badulla.—*Patana* plantations have been extended, *grevillea* chiefly. Hapntale.—Strip plantations have been extended, chiefly *eucalyptus robusta*.

(d) Puttalam.—Teak plantations have been extended and the older portions trimmed.

(e) Eastern Province.—Teak *chenas* have received attention, and something has been done in the way of weeding and re-planting.

(f) Ratnapura.—The Para rubber plantations have been extended.

(5) Timber Operations.—Supply to public depôt.—Chief works, Badulla Kachcheri and hospital, Annradhapura hospital, &c., sleepers of red doon from Sabaragamuwa and kumbuk from Central Province and North-

Western Province, supplied to public. Local demand met. Also felling of ebony in North-Central Province for China market, only a small quantity auctioned, but fetched excellent prices. Satinwood export to England has been started, with a brisk demand. Halmilla, export to India reduced.

(6) Miscellaneous.—(a) *Chena* cultivation was brought under further control.

(b) Steam saw-mill received and sent to Batticaloa.

(c) Elephant establishment started; there were three elephants, one died.

(d) Very complete and interesting collections of timber and minor produce exhibited at the Agricultural Show.

AGRICULTURAL EDUCATION IN 1891.

The work at the School of Agriculture has been most satisfactory, to judge from the report read by the Superintendent, and the comments made by the speakers, on the occasion of the prize giving in November. The classes consisted of 26 students—all resident pupils except two day scholars. Six of these passed out at the end of the year having gained certificates of merit after a two years' course of training at the School. The labours of the Agricultural Instructors have also been attended with good results, as is evinced by the fact that applications for their services continue to be made by Government Agents and Assistant Agents, while the Government has sanctioned the employment of six extra men during the present year. An area of 40 acres of land adjoining the School was granted by the Government for experimental cultivation, and a good type of stud bull was imported from India, to be stationed at the School. It is likely that the matter of improving the native stock of the island will be taken up in a more active way in the future, and that during the present year a veterinary surgeon will be added to the staff of the School. Schemes are also in contemplation whereby a technical branch will be grafted on the School, and the various establishments for training teachers will be centralized at the School of Agriculture.

THE FISH LEAF.

I am much beholden to "Károly Fűrö" for his friendly and instructive notice of my short paper on this germ leaf, or birthcase, or navel of the tea bush. He has given us quite an interesting lesson in Tamil, more about which further on.

Seeing my "discourse" in print, I observe one or two expressions that may draw upon me adverse criticism. For instance, "the whole art of plucking" is a large order, and may be misconstrued. Nevertheless it correctly describes the revelation that flashed into my mind, in "an instant,"—and not only the whole art of plucking, but the whole art of *pruning* also. By this I merely mean the fundamental law underlying both operations, independent of age, soil, fat, climate and condition of the bushes. How each of these things affect both operations in actual practice, is another matter, and might easily be told, if that were my object, which—being only the name and nature of the Fish Leaf—I have nothing to do with.

That part of my paper where I attempt to fix *Min-leei* (fish-leaf) upon *Min-leei* (first-leaf) was rather a *jeu-de-mots* than a serious intention, because—as I explained, Tamil came too late on the field. I never heard the coolies call it "Mun-leei" (though I have pointed out to them it would not be a bad name for it), and, frankly, I do not believe it has anything to do with it. After reading "Károly Fűrö's" note *minimiu pootchi* (glow worm), *minnal* (lightening) *van min*, (stars) and *Minatchy* (fish-eyed maiden) will remain fixed in my memory, and also the root "min" to

shine,—which, by the way, almost points to the fact that Minatchi would be best rendered Bright-eyed than Fish-eyed, following Vellatchi (light eyed, or silver eyed), Tanzatchi (golden-eyed, as well as younger sister). But I suppose there is a difference between "Achi" (a mother), and "Achi," which probably comes from some root meaning eye. "Károly Für ö" is better able to explain. Most u's are pronounced as i (in pin) by the coolies, so that I don't quite follow "K. F." in objecting that *min* and *min* are easily confounded; but cooly-Tamul (or Tamil) is doubtless a fearful and wonderful thing. I owe my knowledge of the meaning of "Toppul *alai*" to a Tamil gentleman of the Edinburgh University, and I found the coolies had to think twice before they could see the connection.

R. W. J.
NOTE BY KAROLY FURDO.—It is quite refreshing to find anyone taking interest in anything beyond the mere routine of tea manufacture, and going into the why and wherefrom as "R. W. J." is doing. I quite concede that in Tamil short *i* and *u* and long *i* and *u* are interchangeable, but what I cannot admit is that short *u* is ever pronounced like long *i*, or that *min* could ever become *min*. And now I am sorry to see that "R. W. J." has flown off at a tangent regarding the *achchis*. *Kām-ūlchi* means "love-eyed" or "amorous-eyed"; but *Velleiochi* (the white woman) is only the feminine form of *Velleiyan*: and *Tangachchi* is the fem. of *thambi*, younger brother, which is a contraction of *Tham-pin*, after one's self, as can be seen by the forms *um-bi*, your younger brother: *em-bi*, our younger brother &c. KAROLY FURDO.

SALE OF PLANTATIONS IN 1891.

NOTES ON PRODUCE AND FINANCE.

LAST WEEK'S SALES OF TEA.—The demand for Indian tea, says the *Produce Markets Review*, continues active, and a large business has been transacted in all kinds. The tendency of the market is stronger, more particularly for the medium and lower grades the latter having risen from ½d to ¾d, and from the lowest point about ¾d. Notwithstanding this advance, prices are quite 1½d lower than at this time last year, and providing there is no further material increase in values, there is no reason to anticipate any check in the satisfactory demand. On the other hand, if any attempt to force up prices to an unjustifiable level met with any measure of success, it would be sure to stop the demand, and similar unsatisfactory results to those experienced in the early part of the year would have again to be contended with. The quantity of Ceylon tea offered has again been small, and prices are firmer. The demand from the country has somewhat diminished, chiefly owing no doubt to the cheapness of Indian teas, which at the moment, except where Ceylon flavour is

demand, undoubtedly show superior value. The quality of the imports during the week has shown a slight improvement, and as reports from the island point to better weather, teas of good quality may be on the way. Java teas are much neglected except for export, for which the demand is rather more active. The arrivals for the week are:—The "Clan Buchanan," "Gelconda," "Mira," and "Legislator," from Calcutta and Colombo; "City of Canterbury," from Calcutta; and the "Oroya," from Colombo. Notwithstanding the near approach of the Christmas holidays, says the *Grocer*, the quantity of Indian tea brought forward has continued heavy, reaching 32,985 packages, which, it is satisfactory to say, met an active demand, and were nearly all taken off with a healthier competition than for some time past, at a further slight advance. The common sorts are gradually recovering from the recent depression, and are now $\frac{1}{2}$ d to $\frac{3}{4}$ d per lb. dearer than they were a fortnight ago. The better and strong-liquoring kinds also have been more readily purchased, and still form the smallest proportion of the general supply.—*H. and O. Mail*, Dec 25.

DOOM DOOMA TEA COMPANY, LIMITED.

The following circular has been issued to the shareholders:—"I beg to inform you that at a meeting of the directors of this company, held on the 16th inst., it was resolved to declare an interim dividend at the rate of 5 per cent. upon the whole capital of the company, namely:—To the A shares, 5 per cent.; to the B shares, 5 per cent.; and to the ordinary shares, 5 per cent. In conformity with this resolution, I have now the pleasure to forward a dividend warrant for the amount due to you, as per accompanying statement. I am instructed by my directors to inform you that the total tea crop of this season, including that of the Samdang Garden (about 98,000 lb.) amounts to 1,120,960 lb. as compared with 893,890 lb. last year. The sales up to date of 733,337 lb. in London have averaged 10 15-16d. per lb., as compared with the average to same date last year of 9 9-32d per lb., or with the total 1890 average of 1s 0½d per lb.—I am, yours obediently, E. G. Rock, Secretary."—*H. and O. Mail*, Dec. 25.

SAPPHIRES AND RUBIES IN SIAM.

The first annual ordinary meeting of the above company took place on Monday.

Lord Thurlow, the chairman, in speaking at some length, said that matters were progressing as favourably as could be expected in the face of the many difficulties they had had to contend with.

Mr. C. Preston Gibbons, who was at the head of their affairs in Siam, had been dangerously ill, and the fever so prevalent in that country had at first attacked many of the men on the fields. The company, he continued, had now taken possession of nine square miles of gem-producing ground, and the result had been 210,000 carats of sapphires and rubies, 40,000 carats of which had already come to hand, a second consignment of 130,000 carats being expected shortly. They had as yet not exported any expensive machinery, trusting rather to the simple appliances by which the natives were accustomed to extract the gems. They would not risk sending out expensive machinery, &c., until they had extended their business sufficiently. He regretted to say that the bank balance in London was very small, and that they would have to make a call of 2s. 6d. in the £ payable on Jan. 15th. This would enable them to keep the concern going for six months. He did not think a further call would be necessary, as they were receiving consignments of stones for disposal, unless they extended their operations largely. He congratulated the shareholders on their excellent staff, both in Siam and in London, and also on their relations with the Siamese Royal Family and Government, who were largely interested in the undertaking, and whose patronage would contribute greatly to the success of the company. In conclusion, he moved the adoption of the report and accounts. The motion having been unanimously agreed upon, the meeting closed with the usual vote of thanks.—*H. and O. Mail*, Dec. 25.

A GUIDE TO RICE-GROWING.

Near the end of the last century the reigning Emperor of China, Kaughi, the second of the present dynasty, impelled by the importance of the rice industry in the Flowery Land, and to show his solicitude for the welfare of his subjects, published a sort of guide to rice-growing. This curious work (dated 1796), which suggests to the European mind that the Emperor compiled it when in a playful mood and rather as an amusement than out of regard for the welfare of his subjects, has been rendered into English, and as it may be of interest to our readers we produce the translation (kindly lent by Mr. Alex. Macpherson) in full. It should be mentioned that each of the short descriptive verses given below is accompanied by a picture:—

SOAKING THE RICE SEED.

The rains have fallen and brought water to our cottage gate.

Immerse your bamboo baskets of seed in the limpid waters, and soon the precious grain sprouts will show forth.

It is now that outdoor preparations begin.

Sacrifice the fowl to greet the opening spring, and offer up your prayers for an abundant harvest.

Let the plough do its work from morning till night.

PLOUGHING.

Good! The water in the fields has accumulated to the depth of a plough.

How beautiful to see the vernal foliage casting its shade on the land.

Aged as I am I delight to saunter from the cottage door, and with the aid of my staff I come to watch the water buffalo laboriously wading the muddy flats.

Alas! in how many years gone by have I put my shoulder to the plough!

HARROWING.

With my bamboo hat I brave the morning mist.

With my bamboo leaf coat I resist the rains of spring. See the poor buffalo.

The mud is four hoofs in depth, but who will say that he works harder than I, the man behind, who from morn to eve stand till my legs ache with fatigue?

RAKING.

Off with your coat and out to your work.

Harness the buffalo and rake all the fields.

Such is the morning cry.

Now, soon will the sun be sinking in the west,

and already I hear the song of returning woodmen.

Ah, my good buffalo! thou art quickly to go home and enjoy your evening swim.

HARROWING.

Wo! Steady, my beast.

Now, gentle reader, while your rustic friend reins in his buffalo, please take a glimpse at his native village. A single row of thatched cottages along the margin of a lake backed by bamboos and other foliage, and there you see a specimen of quiet Chinese rural life.

SOWING.

The land is prepared, the grain is sprouted.

Entering the field with each a basket on his arm, We walk backwards, and with a wave of the hand deftly disperse the seed.

Ere a few days have elapsed the tender blades will be bending before the wind.

Thus by a picul of seed may a full harvest be reaped.

THE FIRST SPROUTS.

The warmth of spring has started the seed, de,
And with staff in hand and a youngster by my side
I hobble out to see the first green blades;
This is the first result of this year's work;
But how much more is there yet to be done.

MANURING.

Our system of agriculture has been handed down to us by our forefathers.

Without manure mother earth will not yield in abundance.

Such is a portion of our labour.

Let us hope that we shall reap abundantly.

TRANSPLANTING.

The young plants have reared their heads above water;

Fathers and sons all lend a hand to transplanting.
We gather up the plants in bundles sufficient to fill the hand.

We will plant them east and west in the broad fields.

TRANSPLANTING.

At early morn we began our work.

The plants must be sown in straight lines and evenly apart.

With the bundle on the left arm we plant with the right.

Beginning from the left each his line towards the right.

Amidst song and talk thus we pass the day.

This is the husbandman's busiest of times.

WEEDING.

The rains have been falling.

The plants have taken root,

But the weeds have started and are invading the soil.

They must be eradicated as should all evil things.

So up to our knees in mud we walk between the plants,

And with the hand pluck up these noxious foes.

SECOND WEEDING.

If you take off your coat the sun will scorch your back.

Although wearing a hat the perspiration trickles down one's neck.

But can we refuse to brave the heat of the day?

Who! the work is very hot.

But here come the good ladies

With a pitcher of tea and something to eat,

And see, they bring the little youngster.

Is it that he may take an early lesson in agriculture?

WEEDING.

The paddy grows up, right glad are we.

But yet another weeding, or ill 't will be.

To get our daily meal how hard it is,

For all our toil and labour

Is but with the view to fill the stomach.

IRRIGATING.

There was a man of the time of Sung,
Because the paddy grew slowly he pulled it up an inch,
And returning boasted how he made things grow.

There was a man of the Tang Dynasty

Who watered his field with a cup

And thought he would do what others could not;

But we of this wise generation,

We use chains, pumps, and buckets,

And never do such foolish things.

REAPING.

With our hawks bent well to our work

The sickles ply from right to left.

Come, boys, and gather up the leavings.

The sun is already in the western horizon.

Burdened with the fruit of the soil

We return with joy to our humble homes.

STACKING.

See the stacks how they rise on high,

There, then, are our winter supplies;

Our minds are at rest,

For we have plenty to eat,

And our labour is easy from this time forth.

THRASHING.

When the hoar frost sets in

The leaves begin to fall and the weather is fine;

This is the time we choose for thrashing.

From the open space before the cottage

The noise of flails resounds afar;

The fowls pick up the straying grain,

And the black crows sit kwaing on their porches around.

POUNDING.

The rustling sound of wind is heard without,

The noise of pounding goes on within,

We pound the grain by hand in a tub,

We pound it also by working with the feet,

And while this scene goes on

A neighbour may be drops in;

To talk of crops and other things.

SIFTING.

Before the winnow the grain must pass the sieve
Fine work it is for our arms.

With a bamboo cope to shelter us from the wind,

A youthful wife from the window looking on,

And the bright sun spreading warmth around,

The time passes busily but pleasantly along.

WINNOWING.

The wind is high and good for winnowing,
The grain drops down with noise like rain,
While the chaff being light is blown with the wind.

As we fill our baskets and measure what's left

We are thankful that with plenty we are blessed.

HULLING.

The husk has been, you've seen, removed;

There is the skin of the grain to go;

The wherefore of it's ground between two stones,

Three men to push and pull and one to erve

he while

And one more sifting, and the grain is rice for

human kind.

STORING.

It is winter, the weather is very cold,

Many of us seek warmth in the sun without,

While our cattle we house secure from the wind.

See how we store the rice in bulk,

The officials will now come to collect their tax.

RETURNING THANKS.

The spades and forks are now put away,

The sieves and baskets no longer required.

One year's operations have thus rotated,

And on our knees before our altar god

We give offering and thanks for blessings vouch-

safed.

—Queenlander.

SOUTH WYNAAD NOTES.

Jan. 2nd, 1892.—* * * There is no blotting out the fact that though on some estates, crop this year has been all that could be desired, on others, it has proved a failure, perhaps the more keenly felt on account of the previous brave promise, so pleasantly held out to us at blo-oming time. The blossom of 1891 was an exceptionally fine one, and to all appearance it set with every prospect of success. This was followed on some estates by wave after wave of leaf disease. Still crop remained visible in most satisfactory quantities upon the leafless branches. The first result of such denudation was that the berries dropped off in large numbers, the next, that the trees, unsheltered and sapless, refused to ripen their fruit, and this either blackened and shrivelled up, or remained green and unfit for pulping. As I write, whole fields are to be seen here and there as green as though we were in September instead of January. Another effect of the continued leaf disease is, that much of the coffee, apparently perfectly good, contains, when pulped, a large proportion of floaters, whilst amongst the parchment are to be found many discoloured and spotted beans. All these little difficulties have considerably taken the gilt off our gingerbread, and if we in South Wynaad depend entirely upon Coffee Arabia, it would be anything but a bright look out for most of us. The high prices help us to and we can heartily rejoice with those fortunate whose crops have turned out trumps; and as I have always said, there is no need for us to strike our colours because one industry in one locality is more or less a failure.

We are perfectly and thankfully conscious that other things will grow and flourish in Wynaad, and that only money and enterprise are needed to make us prosperous again. At the same time, from what I see just round me, I venture to doubt the wisdom of stating that the prospects of coffee Arabia are entirely flourishing. The young fields may look well and promise hopefully, but with the soil and atmosphere saturated as they undoubtedly are by vastatrix germs, it would be absurd for us to suppose that our enemy is conquered. That this is not a mere craze of my own, as some of your correspondents have asserted, is proved, for my statement is practically supported by the fact that a very considerable acreage has already been planted up in Wynaad with Liberian coffee, and that almost every one who objected to the idea twelve months ago, is now acknowledging the force of such visible arguments as abandoned estates provide, and making

the most of every available acre for the cultivation of Liberian. I have heard several discussions on the subjects of grafting and inarching, and I know that here, grafted and inarched plants of Arabica and Liberian have been procured from Bangalore for the purpose of studying the process carefully, but from what I can gather, it is not generally regarded as likely to be of much use, the argument against it being, that it is the delicate thin leaves of the coffee Arabica which are susceptible to disease, and that merely grafting cannot alter their texture, or thicken them sufficiently to enable them to resist the germs; whilst grafting Liberian upon Arabica is ridiculous on the face of it, for surely the Liberians own sturdy roots must be the most suitable for its well being.

There is a good deal of talk about tea; and I am very glad to say, something a great deal more solid besides talk. Two well-known properties hereabouts are now being opened for tea, and reliable famous hints at an Agricultural Company, with tea for its principal product, which is to be started before long. This will embrace some old abandoned estates, as well as properties still in cultivation, all admirably situated for the purpose, and this should prove a good step in a new direction. There can be no doubt whatever as to the suitability of Wynaad for a tea-growing country, and its introduction, practically, should commence a new and prosperous era for us all. It does not take so long to come into bearing as Liberian, which is also an advantage, and so far such as has been grown here, has apparently been exempt from disease of any sort. An experienced Ceylon planter lately gave it as his opinion that this district was in every way good for tea; and expressed his surprise that it had so long been a neglected string to our bow. I hope in my next to tell you more of what I am at present only at liberty to mention as a rumour. We are beginning to cry out for rain. There has been none since the middle of November, and the country has begun to dry up considerably, which naturally causes us some anxiety on account of our young plantings. There is a really fine show of wood for next year, and the spike just beginning to sprout is healthy enough, and we are anxious that it should not be forced by too early rains, so that we feel somewhat like the farmer who, hearing there were to be prayers for rain, suggested that the petitions should be on account of the corn fields only, as he had not then got in all his hay! We want rain badly for the new clearings, and we do not want it at all yet a while for the spike. Starving cattle are being driven in already from Mysore, the price of grain is very high, and our Canarese are becoming very humble, and evidently wish to remain as long as possible on the estates, instead of, as usual, longing to hurry off to their own country.

By the way we have discovered a new and abominable poechee, which some one cheerfully suggests is to be the future plague of the Liberian. This is a beetle, about an inch long, narrow, and grey in colour, shaded with black. It has very long antennae and as one writer described it, "a mouth like a b'elephant, sir." Its particular talent is whittling. No American, however accomplished in that national pastime, could beat our beetle. It will work in one night through a stem as thick as a man's wrist, entering round and round with mathematical regularity and neatness, until so small a bit of wood remains that the branch breaks off. It is not particular as to the plant. On three occasions I had fine crotons entirely destroyed, the main stems having been cut through then the beetle wandered to the opposite side of the garden and out down the long, climbing stem of a beautiful *Gloire de Dijon* rose. His last freak was cutting through a thick old branch of Bougainvillea. I hinted in vain for the culprit, and tried my best to the motive for such seemingly purposeless mischief. I can only suppose that it is in some way connected with the depositing of its eggs. Later on a specimen was caught upon another estate, which I put under a finger glass for observation. It seems to eat *moorikah* leaves (*Erythrina Indica*) and it was absurd to see it go for a date stone, and clinging round it commence

whittling. This did not last long, however, and by the next morning the beetle looked very sick indeed; and had not made much progress upon his date stone. I wonder if any of your readers can give us some information about this beetle, especially as to its motive for felling shrubs in this inconsiderate manner.

I have heard of several coffee robberies, but nothing very serious, and the police have undoubtedly been much more active this year than usual. There was one rather amusing case some weeks ago, in which a gang of Pannians made a most determined attack upon the watchmen, returning three times, and being as often pluckily repulsed by the writer, who had come to the rescue. It ended by sending for the police who, however, failed to capture the would-be thieves. These, no doubt, belonged to a well-known robber's village at the foot of the ghats.

Very high prices are being offered for coffee, both parchment and cherry, by the various Coast firms, RS4 for parchment, and RS4 for cherry per bushel being locally offered, so that all expenses of curing and cartage to the Coast are saved, and several of our planters have availed themselves of so convenient an opportunity of disposing of their crops, without the additional trouble and expense of home shipment.

There are several new openings being made for cinchona, which shows there is still hope felt for the future of this product, in spite of the miserable prices at present offered, which make it hardly worth while to harvest our bark. * * *

I think we all very heartily congratulate our fortunate-brethren in Coorg, and rejoice for them about their splendid crops, whilst we hope that we ourselves may rank amongst the lucky ones next year, *Floreat Coffea!* wherever it may be. — *M. Times*, Jan. 7th.

TEA IN VICTORIA.

From the review of trade and commerce for 1891, in the Melbourne *Argus* of Jan. 1st, we quote the notice of the tea trade. The record regarding Ceylon tea is similar to that from London,—increased import and consumption but quality and prices low. The benefit of the increased consumption and the taste it must create will come in following years.

TEA.—Contrary to general anticipations the trading results of the first half of 1891 were generally unsatisfactory, caused mainly by the unexpected discovery of stocks in bond, which converted a prospectively bare into an over-supplied market. The repeated errors in our Customs department are beyond all reason, and have called forth the strongest condemnation of its inefficiency from all branches of the tea trade. However, it is generally believed that the stocks are now correctly stated, and that is something. The second half of the year has disclosed a rapid increase in the demand for blended teas, and consequently increased sales of Indians and Ceylons, and a decreased sale of all China kinds. There has been throughout an absence of excitement, and holders in first hands have continued almost nominal, which fact alone would have caused, in view of the small quantity of leaf now afloat and the state of the various exporting markets, speculative sales but for the necessary caution now being exercised in all branches of trade in the present unsettled financial state of the minor monetary institutions of Victoria and adjoining colonies. The most marked change has been the heavy increase in shipments from Colombo, the total from May to November being 2,150,000 lb., as against 1,550,000 lb. for the same period last year. The greater bulk has, however, been of undesirable and inferior grades, and the results to shippers unsatisfactory. From Calcutta, for the same period, the figures are respectively 3,750,000 lb. against 3,480,000, and here again almost the whole has consisted of commoner kinds, for which prices have throughout ruled well under cost, while for the few better sorts and fine teas competition has been sufficiently good to show covering rates. The very low range of values that has existed for blending kinds of Ceylon and Indian teas has so far assisted

their consumption that the increased shipments were fully justified. Having forced their way through their cheapness, they have still further strengthened their increasing hold upon our markets. From Foochow the figures read 13,500,000 lb. against 12,750,000 lb., an apparent increase in trade, but there was a further addition of 2,500,000 lb. last year to complete the season, as against the present on look of about 1,000,000 lb., thus foreshadowing a still further decrease in the exports from Foochow, the cause of which is solely the improved demand for Indian and Ceylon teas. The qualities from Foochow have shown a marked change, there having been a heavy falling off in the demand for low common congen, as also for fine and choice congous and all scented kinds, with an improved demand for fair medium flavoured sorts, full flavoured good mediums, and sound liquoring common. All teas packed in cut and original boxes have suffered almost to extinction from locally-packed blends, now freely sold in 5 lb., 10 lb., and 20 lb. tins. With the change in the demand for stronger teas there has necessarily been a change in the distributing channels, the conservative houses rapidly losing ground in favour of the advertising, single-package, and well-managed blending firms. The general outlook for the rest of the season is a fair trade at sound rates, except in New South Wales, where the proposed abolition of duty has completely disorganised the trade for some months to come.

Discoveries made not long ago near the Stabiana Gate, in Pompeii, included the trunk of a tree which an Italian savant has identified as *Laurens nobilis*. Some of its fruits were likewise found, and from their size it is now said that the eruption which destroyed the city must have taken place in November, and not, as previously believed, in August. —*Garden and Forest.*

THE TEA TRADE AT FOOCHEW.—The past year has (says the Foochow *Echo*) proved no exception to the retrograde movement in the Tea trade of Foochow, which has been going on without interruption since 1880. The supply of Congou in that year was approximately 850,000 chests, and it fell off to 345,000 chests in 1891. There has also been a considerable decrease in the supply of Sonchong, Scented Teas and Flowery Pekoes though not a corresponding extent, Oolong alone having maintained its position as far as yield is concerned. The values too have sensibly shrunk in the eleven years. Looking at the Export statistics, it is startling to note that to Great Britain we shipped 7½ millions lb. in 1880, and only 19 millions in 1891. One noticeable feature in the trade of 1891 is the export of Brick tea to the North which is far heavier than any year since 1887. Amongst the events of the year we have to record the failure of two large firms, one English and one American, though we should add that neither one nor the other occurred through unsuccessful trading at this port. Their places have been filled by new firms started on the remaining business of the old ones. With the falling off of the trade it was to be expected that there would be some depreciation in the value of business premises, but the community was taken by surprise in July to find a double property, which was said to have cost \$40,000, knocked down at auction for \$8,000. Expiring leases of Hong have been renewed at about the half of the previous rentals, and an abatement of a third has been made to residents renting houses on the hill.

THE ANNUAL REPORT of the Superintendent of the Royal Botanic Garden at Trinidad has reached us, and, like its predecessors, contains a large amount of useful information about various tropical economic plants and several interesting and instructive illustrations, the most striking being that of a noble specimen of *Corypha data*, surmounted by an enormous panicle of fruit estimated to weigh over a ton. Mr. Hart calls attention to the fact that the large crown of leaves borne by this Palm withered and fell flat to the stem soon after the appearance of the huge panicle of flowers. As the fruit, set and commenced to develop the leaves became

dry, then hung down (as shown in the illustration) and finally fell off, leaving nothing but the crowning panicle of fruit. Mr. Hart remarks: "From the early falling and drying away of the leaves after the period of anthesis, it is fully evident that they cannot assist in any way during the period in supplying or manufacturing the plant-food necessary for the formation and development of the seeds, and that the supplies and material for such purpose must have been accumulated and deposited in an easily assimilated form in the stem itself. This will form an important fact for those who are discussing the movement of fluids in the cells of plants." He points out that morphosis of this character, although rare in temperate climates, is a familiar feature in tropical vegetation. The Silk Cotton-tree, *Eriodendron anfractuosum*, of which a portrait appeared in *Garden and Forest* (iii., p. 341), is cited as an illustration of this phenomenon. This tree produces its flowers and sets its fruit at a period of the year when it is entirely destitute of leaves, the seeds being distributed by means of the cotton attached to them just as the tree is putting out the new set of leaves for the season. Mr. Hart, as he has in previous reports, deplors the want of interest taken in forest-preservation on the island, and the inevitable destruction, under the existing feeling on the subject, of the valuable forests which still occur in some parts of Trinidad.—*Garden and Forest.*

THE MAGAZINE
OF
THE SCHOOL OF AGRICULTURE,
COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for February :—

OCCASIONAL NOTES.

Two plots of land have been laid under *Lathyrus Sylvestris* at the School,—one a sandy soil, the other a heavy loam. In the latter, the plant must be said to be a total failure, for though the seedlings were carefully attended to and watered, they died out after a few inches growth when the dry weather began to prevail. The other plot shows a fairly healthy growth. The plants in this plot are not much exposed to the sun and are growing in a moist place. It would thus seem that in Ceylon at least *Lathyrus sylvestris* is not the hardy plant it is reported to be, and that the hope of being able to cover our poor sandy soils with a nutritious fodder crop must be given up, that is to say if the seed we have been supplied with was not at fault.

The School of Agriculture re-opened on the 16th January. Out of a large number of applicants for admission, 15 students have been admitted.

"Cow-keeping in India" is the title of a work by Isa Tweed, published by Thacker, Spink & Co., Calcutta. The book contains many valuable practical hints, which we hope to give our readers the benefit of as opportunity offers.

Mr. H. S. Dias has been appointed Agricultural Instructor in the Kegalla district.

Received with thanks for the School Museum a sample of silky fibre from the fruit of the wara tree (*Calatropis gigantea*) sent by Mr. Van Starrex of Crystal Hill Estate, Matale; and specimens of felspar from Hanguranketa, sent by Mr. H. S. Dias, late headmaster of the Buddhist School in that district.

At a meeting held on the 27th instant, it was decided that the meetings of the School of Agriculture Improvement Society should be held on the first Friday of each month. Mr. Kehelpanala was appointed Secretary and Mr. Attepattu, Treasurer.

The wealthy residents in and about Colombo, who are willing to give money towards a charitable cause, or for the founding of a really useful institution, could not do better than help to establish a School in Colombo on the lines of the Industrial School of Kandy. This School, as it is now managed by Mr. Donald Jansz, is worthy of all the support and encouragement that men of position and influence can give. In it some 47 boys are being taught tailoring, shoemaking, carpentry, wood carving and fretwork, book-binding, picture framing and such useful industries as are suited to the class from which the boys are drafted. Carriage building on a small scale has also been taken up, and the result of the work of the boys reflects the greatest credit upon them and their Director.

We are glad to learn that there is a fair sale for the articles turned out at the Industrial School, while the orders for printing are many. We have heard it said that the charges made for work done at the School are exorbitant, but excepting fancy articles which might, with excuse, have fancy prices, the charge for other kinds of work is quite moderate. It would be a great matter if some wealthy gentleman would come to the rescue of the School and pay off an old debt that stands in the way of the development of the institution. Not the least important features of the School are the exercise of discipline and the teaching of method.

W. A. D. S. writes of Mudar (*Calotropis gigantea*):—This plant is known in Sinhalese as Wara. It grows in the uncultivated parts of the warmer regions of the Island, and its leaves and stems contain a milky juice of a thick consistency. The milk of the *Calotropis* is very acrid, but is largely used in medicine by Indian native medical practitioners. The milk has also been subjected to experiments recently, and has been found to yield pseudo caoutchouc of some value. The bark of the Mudar plant contains a fine silky fibre, which though of not much commercial importance is used by the villagers for various purposes. Its strength, texture, and appearance are all very favourable. In the fruit of the Mudar, the seeds are found together with tufts of long silky cotton. The staple is long and strong and of a shiny appearance. This cotton is said to be spun and used in the manufacture of a kind of fabric in imitation of Cashmere shawls. In Japan the cotton from the *Calotropis* is used among other things in the manufacture of the strings of stringed instruments. If sufficiently found the *Calotropis* is no doubt capable of being put to greater commercial use. I am informed that not long ago the Spinning Company brought over a quantity of *Calotropis* cotton from Badulla, but so far it is not known whether the staple was found of use, or whether any experiments were made to test its value. The latter course would be a very desirable one, especially in view of the possibility of growing the plant largely if it is found to be a paying crop.

THE CULTIVATION OF THE COCONUT PALM.

To facilitate the process of watering on a young estate, rough wells are dug at convenient distances apart; these, when the trees are in full bearing, are filled up with rubbish, or become covered over by the natural process of the tumbling in of soil. On most coconut estates in the Eastern Province the water level is not far from the surface of the soil; the cost of well-digging is not great at first, but where supplying has to be done the wells (as well as fences and nurseries) must be attended to. Watering is done by means of chatties (earthenware pots)—one chattyful of water being given to each plant. A sloping path leading to the water is generally cut to facilitate the process of watering. When the estate is young there is no reason why vegetables should not be grown—and this is generally done on an open space near the bungalow—as vegetables thrive well till the palms grow up to a extent when the roots and the shade of the coconut trees interfere with such subsidiary cultivation. Jaks, mangoes, oranges, shaddock, and lemons might with advantage be made to line the roads leading to the bungalow or be grown along the fences—they are both ornamental and useful, the fruit commanding a ready sale. In the low ground plantains will thrive well; and pumpkins and melons might be raised among the cassava and Indian corn, while the latter are growing. It is quite common for the watchers and bungalow servants to have their own plots of chillies, brinjals, beans, &c., so that the coconut planter has no lack of vegetables for his table. Many estate proprietors keep no superintendents and trust their

properties to a head overseer or cangany, but for reasons too patent to need mention here, this plan is to be greatly deprecated. The man who lives on and manages his own estate naturally reaps the greatest reward, and a trustworthy superintendent—whether a relative of the proprietor or not, is the next best alternative. Young palms generally bear the largest nuts, and these have thinner shells than the nuts from old trees. The fibre of the latter, however, is the tougher and produces the strongest rope, and the toddy from old palms contains more saccharine matter and is more intoxicating.

Many systems of manuring have been practised in the Eastern Province. The plan of liquid-manuring entails the cost of large vats or reservoirs generally placed below the cattle-shed floors which then need to be planked over. Again special carts fitted with barrels are necessary to cart the manure to the places over which it has to be distributed, and where trenches are dug round the trees to receive the liquid. In one case where liquid manuring was carried out, sulphuric acid was added to the manure before using, but this was found to be an expensive practice, and it was considered doubtful whether it paid. Liquid manuring may now be said to be abandoned, except in one instance, and other modes of manuring resorted to. A common method is to dig trenches 3 to 3½ feet wide round the trees and tie cattle to the palms for 3 or 4 nights running—from 4 to 6 head being employed for the purpose. Their droppings together with dead leaves and refuse from the trees are then earthed up. This is done before the rainy season, so that the ensuing rains may help to decompose the manure and wash down its valuable ingredients into the soil to be taken up by the roots—while little, if anything, is lost by evaporations owing to the covering over of the dung.

I lately visited an estate, of some age, not far from Batticaloa, which is manured in the manner I have indicated, except in the case of a patch in the centre of the property, that is fertilized by the droppings of a herd of some 100 goats. I here had an opportunity of judging of the relative value of goat and cattle manure, and found that the results of the former were infinitely superior to that of the latter. By the keeping of goats and sheep not only will a coconut planter vastly improve his estate, but he will never be in want of meat for his table and milk if necessary. The keeping of these animals entails little expense beyond housing them during wet and windy weather, and engaging a boy, say for every 50, at the cost of 6 or 10 cts. a day.

In this district the fronds or branches which fall, and these only, are plaited after soaking in water, and for every 1000 given to a villager he will return 500 woven cadjans to the estate, keeping the rest for his trouble. At one time it was usual to sell the branches for 50 cts. per 100; those branches not fit for cajan making are allowed to rot and are applied to the ground together with manure. The coconut cultivator should endeavour as much as possible to return to the soil all that falls from the tree, and with this end in view, should throw into the manure trenches the rotten branches, husks, &c. if possible mixed with jungle leaves. The natives use the dry flower

sheaths as torches, and the ashes of midribs as a cleansing powder in lieu of soda. Coconut shells are used for burning especially by dhobies in their "irons," as they produce much heat owing to the presence of oil in their tissues; and they are purchased for this purpose. It is a good plan to keep the branches, husks, &c., which fall from the palms piled up between the rows of trees with some regard to neatness, so that when the "coconut fly" makes his appearance, these piles may be sprinkled over with water and fired. The result is that a dense volume of acrid smoke is sent upwards, which causes the insects on the crown of the palm to fall off. Care should be taken not to allow the flames from the burning mass to mount high, as damage might thereby be done to the trees. Green leaves added to the heaps will increase the efficacy of smother-burning. The ashes resulting from the incineration will of course be turned into the trenches round the trees. By this means a bad attack of "poochies," which often costs the proprietor 2 or 3 years' yield of nuts, can be with a little trouble averted. This plan was, I believe, first tried by me on Chandivelly estate, the property of Mr. Stuart Munro (the designer of the antipilfer safe) who showed me how to carry it out. Many years afterwards, when the "poochies" were attacking the estate of Mrs. Sortain, the same process was gone through with the result that the disabled insects were found in millions wriggling on the ground. R. ATHERTON.

INDIGENOUS FOOD PRODUCTS: CULTIVATED AND WILD.

Convolvulaceae.

60. *Ipomoea Tridentata*, Roth. Sin. Heenmadu

This is a creeper growing in the jungles of the warmer parts of the Island. The plant is much branched with a green and cylindrical wiry stem. The leaves are cordate, dark green, and are of a thick texture: a milky juice is exuded from the plant when a leaf or the stem is broken.

The leaves of this plant may be considered as a famine food. The villagers often eat it boiled in water with a little salt added, and sometimes along with coconut. Cattle relish the whole plant very much and hence the leaves are often gathered and given to calves. It would, no doubt, form a good fodder, and as it grows easily, it might well be grown experimentally for trial as a cattle food.

61. *Ipomoea Aquatica*, Forsk. Sin. Kankun.

The *Ipomoea Aquatica* thrives in moist situations as the name signifies. It is a low creeper with a hollow succulent stem which easily breaks at the nodes. The leaves are cordate and are of a light green colour. They are succulent, and when the plant is found growing wild are of a small size, while when cultivated, or found growing in particularly rich soil the leaves attain to a larger size. This plant is esteemed as a vegetable, and is often cultivated especially in the vegetable gardens in the vicinity of towns, where they find a ready sale in the markets. The leaves and the stems are used both as a dry curry and fried in ghee or oil.

It is generally believed that this plant possesses certain medicinal properties, and there is there-

fore some demand for it. Native medical practitioners ascribe to it certain cooling properties.

Solanaceae.

62. *Solanum Ferox*, L. Sin. Malabatu.

This plant is generally met with in uncultivated places, and where the land is at all fertile, they grow vigorously. It is a low shrub, two to three feet in height, and covered with numerous erect spines. The leaves are obovate and angular, with soft hairs on the upper surface, while the lower surface is generally of a whitish colour. The veins of the leaves are covered with strong and straight prickles, the flowers are of a white colour, and the fruits are round and smooth and are of the size of ordinary marbles. The calyx and the petiole adherent to the fruit are also covered with prickles. The fruits when young are of a green colour, and when ripe, turn a beautiful ruby red. The shining pericarp is succulent and a large number of seed is found inside the fruit. The part generally eaten in this plant is the fruit. Correctly speaking, it does not form a food, but the pericarp of the fruit could be eaten and is by no means of an unpleasant taste.

An infusion of the roots of this plant is said to be given in cases of acute rheumatism, and Native medical practitioners use the leaves in cutaneous diseases.

63. *Solanum Indicum*, L. Sin. Tibbotu.

This plant grows wild in jungles and uncultivated places. It is a shrub much branched, and five to six feet in height. The stem is thin and is covered thickly with prickles. The leaves are large and have prickles on both surfaces. The calyx of the flower is also prickly, and the fruits are round, very small in size, and are borne in clusters.

The fruit of the *S. Indicum* is eaten after being boiled, by the villagers, and in small quantities even in its raw state, but in the latter case it has a peculiar bitter taste.

The root of this plant is used by Indian doctors to prepare decoctions. It is considered as a good remedy in fevers and coughs, and the juice of the leaves boiled with the juice of fresh ginger is administered to stop vomiting. The leaves and the fruits with a little sugar are rubbed on the body for itch. Sinhalese Medical Practitioners use this plant in cases of cough, pains in the chest, asthma, and toothache, and prescribe the fruit as a vermifuge.

W. A. D. S.

FOREST PRODUCTS.

The villagers in many parts of the Island have been long accustomed to consider the forest and its produce as public property, which any and everyone is at liberty to make use of. This idea was allowed to prevail till comparatively lately, as there were such vast tracts of jungle land in all parts of the Island; but with the extensive clearing of jungles, mainly for cultivation, it was thought necessary that some measures should be adopted for the conservation of the reduced area of forest land. Now the adoption of such measures through officers appointed by the Government is most advisable, but when rules and

regulations assumed too stringent a nature, the result was to bring on a deal of hardship to the poor villagers who had hitherto enjoyed many harmless privileges. The protection of forests, so that the Government may not lose the produce which is of value is a matter of great importance, and the villager himself would admit that it is to his own interest to help to effect this. Let us for a moment glance at the position of the poor villager of the interior. He may possess some paddy land, but it often happens his condition is so helpless, that he is too poor to obtain even the seed paddy necessary for sowing his fields, much less to secure any manure for the land, or to carry on any agricultural improvements. On his bit of garden land he may grow a few yams, vegetables, or a little grain, and these if they come up well, will supply him with a small quantity of food: but in the villages in the interior of the Island there is of course no sale for anything that can be raised on such land. There is no industry he can take to, and in the absence of any industries he was accustomed to gather beeswax and wild honey, jungle ropes and fibres, tanning fruits and edible berries, fence sticks and firewood either for sale or for barter with the villago traders, or sometimes for his own immediate use. These brought him some little money or the necessaries for subsistence, and were the means by which he employed a part of his time usefully. What the villager complains of in the new forest rules, is the fact that he is now denied the privilege of obtaining these products. The right of collection of jungle produce is now given over to a single enterprising man (not generally a villager) for a nominal sum. What the forest regulations aim at is not the paltry income that accrues, but the protection afforded to the forests. It appears, however, that a better plan would be to encourage the villagers to carry on the work which they were used to, with proper restrictions, and to draw up regulations in such a way as to give them liberty to collect any jungle produce, be it beeswax or honey, jungle rope or fibres, tanning fruits or edible berries, fence sticks or firewood, free of cost, after registering their names with the officer in charge of the forests. The best way to guard against any undue advantages that are likely to be taken, would be to place a check on the traders who should in all cases, before they remove the produce from a district, be made to take a permit to do so.

It would also be for the interest of native agriculture if certain areas could be reserved in different centres as "village forests" for the use of the cultivators, as they appear to do in India. Such reserves would not only supply the necessary sticks and ropes for the putting up of fences around fields, but also yield the firewood necessary for the inhabitants. Above all, parts of such village reserves should form the feeding grounds for the villago cattle, that are generally in need of food, and suffer greatly during the period the fields are under cultivation.

Many a useful industry in connection with forests could be introduced by instructing the villagers as to the value of various products found in our Ceylon jungles, and by explaining how these could be utilized for industrial purposes. I shall note some of these in a future issue.

W. A. D. S.

CEREMONIES OBSERVED BY KANDYANS IN PADDY CULTIVATION.

(Concluded.)

This paper will bring to a close the consideration of the subject I have dealt with in my preceding contributions.

Threshing is of course conducted by buffaloes yoked together. During this ceremony women are not permitted to intrude on the *kalavita* or threshing floor on any pretence whatever, as the Kandyan goyiyas harbour an ill-defined notion of their impurity. But in Beligal Korale, in Kegalle District, and also in Seven Korales (Kurunegala District), women are not altogether subjected to this prohibition. When the ears of paddy are well trodden down by buffaloes so as to separate the paddy, it is winnowed, in order to remove the dust and other refuse which are very often found along with paddy. If the threshing is likely to continue for more than a day, a rude watch hut called a *pela* is constructed by the goyiya, and a watcher is set as a guard to prevent theft and ravages of wild beasts.

After winnowing, the paddy has to be measured. This process is termed *yal karanawa*. It is noteworthy that because the Kandyan cultivator often happens to be illiterate, he resorts to a seemingly queer method of measuring the crop his field had produced. For this purpose a ripe arecanut is taken, and when 40 *lahas* (1 *amunam*) are counted, a line is drawn on the arecanut, and so on, as many lines as there are *amunams*. A *nilakaraya*, or tenant, when he goes to his landlord to tell him the quantity of paddy his field yielded, takes great precaution not to express the number in words, but to offer the arecanut which would clearly indicate the number.

The following is a list of the measures of paddy current among the Kandyans:—

2 Patas ..	1 Manawa.
2 Manawas ..	1 Neli.
4 Nelees ..	1 Kurune.
4 Lahas ..	1 Timba.
5 Kurunes ..	1 Bera.
2 Beras ..	1 Pela.
4 Pelas ..	1 Amunam
12 Amunams ..	1 Yala.

The removal of paddy from and to the house is exclusively performed by women who are required to go through a process of purification.

There are many receptacles of paddy among, which I shall mention the principal ones.

Paddy is generally stored in an *atuwa* or a barn or granary, which is the largest possible receptacle. It is made of wooden planks in the shape of a square and set usually on stone pillars. The best site for the construction of an *atuwa* is in front of or in the middle of a house. The *atuwa* has an opening at the top which is reached by means of a ladder. A *Bibi* is next in size and importance. This is a huge vessel conical in form and constructed of sticks or split calamus (rattan). The largest sized one is capable of holding about a hundred *amunams* or 400 bushels.

A *pes* follows this. It is a large cylindrical vessel made of bamboo or rattan, and will contain about 10 amunams.

The other minor receptacles of paddy are of little importance and too well known to need mention. Certain incantations are uttered by the *goyiya* in the act of storing paddy as a preventative against the attacks of moths and other injurious insects.

The *goyiya* and the parties interested use peculiar technical terms during threshing naming different agricultural implements, &c. These terms though used from time immemorial are yet never mentioned in ordinary language, and are not in keeping with native idioms and dialects. This mode of communication is called *Govi-basava*, or the *goyiya's* language. I was told by a well-informed Kandyan Chief that the object of the *goyiya* in adopting this course is in order to prevent the *Takkhos* (devils) from stealing the paddy and consequent misfortunes!

The following are a few of the technical terms referred to, and I believe they will be of interest to the readers:—

- | | | |
|-------------------------------|-----|----------------------|
| 1. <i>Gongahanawa</i> | for | ploughing. |
| 2. <i>Yatura</i> | " | winnow. |
| 3. <i>Goi Lella</i> | " | leveller. |
| 4. <i>Sakawaliya</i> | " | sweeper. |
| 5. <i>Bolgediyo</i> | " | buffaloes. |
| 6. <i>Pubboruwo</i> | " | rice. |
| 7. <i>Ratta</i> | " | fire. |
| 8. <i>Kotabanawa</i> | " | eating. |
| 9. <i>Ratte Mahat-karapan</i> | " | to kindle a fire, &c |
| 10. <i>Pellai</i> | " | bags. |
| 11. <i>Goyan Madinawa</i> | " | ploughing. |
| 12. <i>Beta</i> | " | paddy. |

Before taking paddy for household consumption, a portion is first reserved called *Akkiyala* as *Dehiyangè*, *Panguwa* or god's share. This is given in the name of the god to the *Kapurala* who is supposed to have officiated throughout. Another portion called *Ahut Bat Dáne*, is sent cooked to the neighbouring *Pansala* for the priests.

A quantity of paddy is then put into the mortar, and three women clad in white with three pestles in their hands pound the paddy at an auspicious hour. A grand feast is next given to relations, at which all the guests including the *goyiya* and his family make merry, afterwards dispersing with every good wish for the coming harvest.

Gampola, 7th Dec. 1891.

THE NITROGEN QUESTION.

The first Quarterly Journal of the Royal Agricultural Society for the year contains a paper by Sir John Lawes and Dr. Gilbert, in which are given the experimental facts in support of Hellriegel's theory that the leguminous crops are able to obtain nitrogen from the air by means of the microbes in the wart-like nodules on their roots. A paper by Dr. Gilbert, lately published, also refers to the Rothamsted experiments to prove the doctrine of Hellriegel. It will be remembered that a little more than

twelve months ago Dr. Lawes delivered himself to the effect that he was no believer in the truth of the latest theory regarding nitrogen, or rather that his (Lawes') own experiment did not warrant his belief in the teaching of the German Scientist. Hellriegel's doctrine, it was said, was anticipated by Professor McAlpine of Edinburgh, who, we can ourselves vouch, explained in his class-room the peculiarities, of the leguminosae, as regards their supply of nitrogen, on the same hypothesis as that adopted by the German, at least a year before the latter published his ideas to the world. We now have the results of a series of careful experiments, which it is not necessary to detail here, and we will therefore merely give a resumé of the conclusion which the Rothamsted experiments have led to:—

"As to the explanation of the fixation of free nitrogen, the facts at command did not favour the conclusion that under the influence of the symbiosis the higher plant itself was enabled to fix the free nitrogen of the air by its leaves. Nor did the evidence point to the conclusion that the nodule-bacteria became distributed through the soil and there fixed free nitrogen, the compounds of nitrogen so produced being taken up by the higher plant. It seemed more consistent, both with experimental results and with general ideas, to suppose that the nodule-bacteria fixed free nitrogen within the plant, and that the higher plant absorbed the nitrogenous compounds produced. In other words, there was no evidence that the chlorophyllous plant itself fixed free nitrogen, or that the fixation takes place within the soil, but it was more probable that the lower organisms fix the free nitrogen. If this should eventually be established, we have to recognise a new power of living organisms—that of assimilating an elementary substance. But this would only be an extension of the fact that lower organisms are capable of performing assimilation-work which the higher cannot accomplish; whilst it would be a further instance of lower organisms serving the higher. Finally, it may here be observed that Loew has suggested that the vegetable cell, with its active protoplasm, if in an alkaline condition, might fix free nitrogen, with the formation of ammonium nitrate. Without passing any judgment on this point, it may be stated that it has frequently been found at Rothamsted that the contents of the nodules have a weak alkaline reaction when in apparently an active condition—that is, whilst still flesh-red and glistening.

"As to the importance of the fixation for agriculture, and for vegetation generally, there is also much yet to learn. It is obvious that different Papilionaceæ growing under the same external conditions manifest very different susceptibility to, or power to take advantage of, the symbiosis. The fact, as shown by Professor Nobbe, that Papilionaceous shrubs and trees, as well as herbaceous plants, are susceptible to the symbiosis, and under its influence may gain much nitrogen, is of interest from a scientific point of view as serving to explain the source of some of the combined nitrogen accumulated through ages on the surface of the globe; and also from a practical point of view, since, especially in tropical countries, such plants yield

many important food materials, as well as other industrial products.

"In conclusion, it will be seen that the experimental results which have been brought forward constitute only a small proportion of those already obtained or yet to be obtained at Rothamsted, but they have been selected as being to a great extent typical, and illustrative of the lines of investigation which are being carried out."

SOME PITH-PRODUCING TREES.

The sola Tree (*Aeschynomene aspera*) belongs to the order leguminosae, and is known among the Sinhalese as Maha-deya-seyembala; another member of this family in Ceylon being *Aeschynomene Indica* (deya seyembala). Both are common in the warmer parts of the Island, and affect marshy land. The pith is much used in various parts of India for manufacturing hats, bottle cases, &c., especially the former, sola being a bad conductor of heat. The material for manufacture is cut from the thick stems and is also made up into artificial flowers and various ornaments by the natives, such as models of temples, fishing floats, &c. The larger plants are particularly light and spongy; they are gathered during April and May.

The Malyns use the pith of *Scavola taccada* (Sin. Taccada) for making artificial flowers, &c., in the same way as sola is used.

The pith of *Aralia papyrifera*, the rice-paper plant of China, resembles sola pith, but it is much finer and whiter. The pith of *Aralia* is used for drawing paper, and has been employed by entomologists for lining the drawers of their cabinets.

Mr. William Ferguson, in his paper on Ceylon Timber Trees, refers to *Aeschynomene aspera* and *A. Indica*, and mentions that sola hats &c. are made from "a spongy substance generated on the stems of these plants when growing in water, as they generally do."

It may be mentioned in passing that *Erythrina Indica* (Sin. Erabodu) a common leguminous hedge plant (used, as well, as a shade tree for young cocoa) also produces a light spongy wood which is used for making models, floats, bungs, as well as toys, especially dolls. It is this latter use it is put to that has given it the name of "Mootchee wood" in India.

Mr. Ferguson informs us that *Aralia Papyrifera*, the rice-paper plant was introduced into Ceylon, and that several plants of it were growing in his time in the Fort garden. The same writer mentions Maha-takkada (*Seevola*) as a seaside plant from the large white pith of which ornaments are made.

The substance commonly called "pith," it will be seen, is not always got from that part of the plant known botanically as the pith or medulla. The word pith (for instance in the name pith-hat) rather signifies a soft spongy material resembling the dry dead cells generally found in centre of the stems of trees.

It is not generally known that the pith of the deya-seyembala has been utilised in Ceylon in the manufacture of pith-hats. Mr. Murray,

the Assistant Government Agent of Hambantota, started the industry of pith-hat making in the Hambantota jail about four years ago, and he succeeded in manufacturing about 100. When Mr. Murray left the station, the industry was given up, but now that he is back again, the work will probably be started again.

There is little doubt that there will be a good sale for pith-hats in Colombo, as visitors to the tropics generally invest in pith-hats before they think of doing anything else, on disembarking in the East; and though pith-hats are to be had at Port Said, it is not always convenient to get them there; so that passengers generally supply themselves with their necessary head gear at Colombo, where they begin to appreciate the heat, rather than wait till they reach India or China. It will of course have to be seen whether pith-hats could be manufactured in Ceylon at a cheaper rate than they are made in and imported from India. It is quite likely once pith-hats are cheaply made in Ceylon, that those who cannot afford to purchase English-made sun-hats at 12 or 15 rupees or even Indian ones at the prices they are sold for in the Colombo stores, would gladly invest a rupee for a Ceylon-made "Sola topee."

GENERAL ITEMS.

Elementary Agriculture is the title of a new text-book written by Dr. Webb, Principal of the Aspatria Agricultural College. A short while ago two other works on Agricultural Science were published by Professor Wrightson of Downton College, and Professor Wright of the Glasgow Technical College, and it is announced that Dr. Fream will bring out a work on Elementary Agricultural Science early this year. There is thus no lack of text-books for our Agricultural Schools and Colleges, but in fact a number to select from. The Manual by Dr. Webb is said to be admirable, both in conception and execution, and only requires to be known to be very highly appreciated.

The varieties of mango grown in Queensland are known as Dohdohl, Strawberry, Alphonse. Gumphor, Bengalee, Saugier, and Gratissima. None of these names are familiar among us, but doubtless these indicate some of the numerous varieties we have in Ceylon, where the largest number of varieties, if not the best mangoes, are grown.

In a lecture delivered before the Society of Arts by A. T. Laurie, M. A., the lecturer stated that Dragon's Blood was mentioned by Pliny, and that it is the resin obtained from the Calamus Palm (*Pterocarpus Draco*, Lin.), Dragon tree.

The leaves of Indian hemp (*Cannabis Sativa*) is said to be a simple and yet most effective means of keeping weevils out of grain. They have been tried with success in Cape Colony, and have been proved to be harmless to everything but the weevil. The leaves are simply placed about in the bags containing the seed. All grain-growers should have a few bushes of *Cannabis Sativa*, which grows rapidly and is easily propagated from seed.

"Stock-owners would do well," says the *Indian Agriculturist*, to cut out and preserve the following recipe, which is an excellent ointment for wounds in horses and other stock. It is known as "green ointment." Take lard 6 oz., yellow resin 1 oz., Venice turpentine $1\frac{1}{4}$ oz., acetate of copper 1 drachm. Melt the resin and copper (with a small piece of the lard to prevent burning) in an iron ladle, and the lard and turpentine in a hot water bath: mix all together when thoroughly melted. As it cools add 2 drachms of turpentine and stir occasionally.

Land surveying is said to have had its origin in Egypt more than a thousand years before the Christian era, where the annual inundations of the Nile, and the consequent large deposits of mud, destroyed the landmarks of the different proprietors. It therefore became necessary to determine these landmarks by measurement, or to lay out the proper quantities of land claimed by the several proprietors irrespective of their landmarks thus destroyed.

An extensive slip of land—over fifty acres in extent—was reported to have occurred on Kandunwara Estate in the Matale district. The uncommonly heavy rains in January no doubt rendered the underlying rock soft and incoherent by the action of the increased underground flow of water, while the steepness of the land must have greatly aided the sliding down of the surface soil.

Mr. Abeyesekere, a student of the School, has brought for our Museum a number of eggs, of absurdly small size, laid by an ordinary country hen. The smallest of these is less than half-an-inch in diameter.

On the 18th, a cow at the School dropped two calves—one fully formed and alive, the other a dead fetus, a few inches in length and imperfectly developed.

Mr. James Storrey, of Kansas City, claims that the artificial production of eggs at a phenomenally cheap rate is now an accomplished fact, and he is proving his own belief in his contention by erecting a large factory to work the invention which he has patented for the production of artificial eggs. The raw material which he uses for the production of artificial eggs are lime water, bullock's blood, milk, tallow, peas, and a few other odds and ends, including some chemicals, the nature and composition of which are known only to the inventor. The machinery used by this egg manufacturer is said to be very ingenious. The yolk is first run in a mould, and then placed in a second matrix containing the proper proportion of the albuminous substance which stands for the white, after which the whole is covered with a shell made of lime water and glue, which hardens after it is set. Mr. Storrey guarantees that his artificially-made eggs will keep 'new laid' for a month, and that the total cost of this production is so low that they can be retailed at $1\frac{1}{2}$ d per dozen.

THE
TROPICAL AGRICULTURIST
MONTHLY.

Vol. XI.

COLOMBO, MARCH 1ST, 1892.

[No. 9.]

SETTLEMENT OF THE TEA SALES QUESTION.

We are sincerely glad to learn, as we do by our London Letter last received, that the matter of Ceylon tea sales in the Mincing Lane rooms has been satisfactorily determined. Indeed, it seems diffi-

cult to understand why, the Committee of those rooms being ready and able on the first application to grant every desired facility, that we here and the trade and its brokers in London should for so long have had to submit to disabilities which we have little doubt have often been the cause for low prices having been obtained for our teas. The Committee has readily granted the use of a second room; and it seems to be matter of general agreement by the brokers that Ceylon sales shall proceed in it throughout the whole of Tuesdays and Thursdays, simultaneously with the sale of Indian sorts in another room. Whether this present limitation to the two days will eventually be found to suffice for the demands of the increasing trade in Ceylon teas it is not possible to say; but should it prove to be incommensurate with that demand, the Committee, it would appear, raises no objection, should it be necessary to do so, to sales being held on every day of the week. The determination to follow such a course will rest at any time with the brokers engaged in the trade. If they find it imperative to absorb another day, or even more days, they can do so by arrangement among themselves without the chance of objection being raised by the proprietors of the sale rooms. For the future, therefore, we ought to hear of no more complaints as to the impossibility of giving a sufficiency of time for the exhibition and testing of samples, though doubtless it will be desirable that our shippers should bear in mind the necessity for giving to their brokers greater latitude as to time than they have hitherto enjoyed, in deciding upon placing the shipments entrusted to them upon the market. The only difficulty which would seem to be apprehended by the wholesale trade is the necessity which the concurrent sales of Indian and

Ceylon teas will place them under of providing additional buyers. It is evident one buyer cannot be attending to the sales in both rooms at one end the same time; and doubtless the increase of the staff required will be viewed by a good many among the dealers with some amount of dissatisfaction. But this cannot be helped, and we are told that the dealers have expressed themselves ready to submit to the necessity involved in the change. To many of them the burden must prove to be but a slight one, because the largely decreasing volume of the China teas dealt in must set free to a very great extent the buyers the dealers employ in that branch of their trade. We expect, therefore, to hear but of little opposition to the new arrangement, which came into operation on the 15th December last. Proof has already been afforded to, and before quoted by us, of the serious monetary loss to which the system now abandoned has subjected our planters, and we hope that the concessions now yielded may have a sensible effect in maintaining the prices of our teas at more level standards. At the same time, however, as we permit ourselves to express the expectation that such a result will follow the new arrangements, we would ask our planting brethren not to neglect the many warnings they have of late received as to other points by which they have themselves contributed to the serious fluctuation which they have had to submit to.

NOTES FROM OUR LONDON LETTER.

LONDON, Jan. 1st.

There has for some time been a lull in the announcement of new companies starting in the tea enterprise of Ceylon; but one has just been announced which, from the weight of the names concerned with it, will probably attract much support. The following cutting from a financial paper will give you all the information as yet possessed by me with reference to this new venture, though it may be hoped that by the time of my next writing it may be possible for me to afford you further details; respecting it.

Mr. John Hughes has addressed a very lengthy letter to the *Grocer* (or it may be to the *Spicer*, if there be such a paper, for the handwriting attached to the extract lent to me is so bad that it is impossible to accurately determine the name of the paper) on the subject of "the agricultural value of shoddy." You will recollect that this subject received much ventilation in your columns at the time the proprietors of the Mariawatte estate decided, on Mr. Hughes' recommendation,

on making a trial of a manure of this nature. The results to that trial do not seem to have had public announcement as yet, so that we are ignorant how far Mr. Hughes' recommendation has been justified by results. The letter by that gentleman tells us that "the value of shoddy, or woollen waste, as a manure for hops, has long been recognized in this country; and in Italy, in the crude form of old rags, it is at present largely applied as an economical dressing for olive trees." Reference is also made to the single trial as yet made in Ceylon, and Mr. Hughes writes that the manure promises to be an excellent fertilizer for tea.

Owing, however, largely to the bad quality of much of it that is manufactured, Mr. Hughes says that the use of the manure has largely decreased in Kent, and he warns intending users that much must depend on the quality of the supplies they obtain. Prices quoted in the letter show that these vary in an upward ratio with the higher quantity of ammonia present, the increased amount of organic matter, and the decrease of mineral matter and water. These prices range over twelve samplings from £1 3s 5d to £3 6s 4d per ton. The nitrogenous organic matter, upon which the agricultural value as a manure chiefly depends, varies from 62 to 26 per cent. A variety of other constituents go to make up "shoddy." Of mineral matters alone there are no less than twelve, these being lime, magnesia, potash, soda, oxide of iron, alumina, phosphoric acid, sulphuric acid, carbonic acid, chlorine, soluble silica and insoluble siliceous matters. Who would have thought that our cast-off coats and trousers could contain such a variety even as that above quoted, and of course there are many more of a different nature which might be added to that list! It appears that two tons of "shoddy" manure are required for each acre of hops, and this quantity yields gradually 358 lb. ammonia, 113 lb. of soluble silica, 90 lb. oxide of iron, 65 lb. of lime, 52 lb. sulphuric acid, 12 lb. of potash, and 6 lb. of phosphoric acid. Space does not permit me to quote further from Mr. Hughes' letter, but in view of the favourable opinion expressed by him as to the applicability of this manure to tea, it seemed to me desirable to call special attention to it.

Another long letter, which appeared in the *Morning Post* of Dec. 25th, deals with the subject of Indian tea, and quotes largely and appreciatively from an article that appeared in the *Ceylon Observer* just received, in which you most justly condemned the character of many advertisements of China teas as calculated to, and as intended to have the effect of injuring the reputation of Ceylon teas. We do not know who the writer of the letter is, as he conceals his identity under the *nom de plume* of "Mincing Lane." He writes, among other much sensible matter, that "Indian teas cannot be placed (as the writer of the article in the *Ceylon Observer* would have) in the same comparison with the good old China Ningchows as Ceylon teas can. At the present time Ceylon Pekoe selling at from 11½d to 1s 2d per pound in the market are generally equal to the finest old China tea which, 15 or 20 years ago, realized 2s 6d to 3s per pound, and by far superior to the best of the same class that arrive now and command at the opening of the season on the average about 1s 6d to 1s 8d, and a few chops of exceptionally fine 1s 10d to 2s per pound." It is to this fact that the writer attributes the rapid ousting of China by Ceylon teas. He closes his letter with a vigorous calling over the coals of Sir Andrew Clark for his late uncalled-for assertion, though he admits that in one sense that distinguished *medico* hit the right nail on the head when he

qualified his dictum with the remark "if the right quantity be put in the pot."

You will be glad to hear that the matter relative to the holding of Ceylon tea sales in Mincing Lane has now been definitely and satisfactorily settled. The proprietors of the sale-room have acceded to the request of the wholesale dealers that a second room should be granted for the sale exclusively of your production, the concession being made from the 15th December. We learn that for the present the brokers propose to limit the use of this room to the entire of Tuesdays and Thursdays, believing this will afford all facilities required; but as trade extends, and if it may be found necessary to do so, there will now exist no obstacle to sales being fixed for every day in the week. The arrangement now made will not be without its inconvenience to some of the wholesale buyers, because it will be necessary for these to increase their staff of buyers, as the sales of Indian and Ceylon teas will now proceed simultaneously, and a single agent cannot possibly attend both. The larger men in the trade, we are told, assert that they will not consider this to be a burden on them, as the decreased sales of China teas will enable them to utilize the services of the men employed by them in that branch of their business. There is now every prospect that we shall have no more complaints of difficulties in the way of properly examining and testing the large number of samples exhibited by the brokers, though the circumstances attending the sales render it desirable that your planters should send home as large breaks as they possibly can.

Noticing in the last received *Overland Observer* the letter addressed to you by Mr. Price of the Brokers' Association on the subject of the alteration of estate marks on many of the tea chests received here, I this week sought and obtained an interview with that gentleman. We discussed the subject of his complaint in all its bearings, and, as the result, we could come to no other conclusion but that the alterations must be made in Colombo. Mr. Price assured me that they could not have been made on this side, as it would be in direct contravention of all the Customs rules to do so, and these are strictly, and with the greatest care, enforced by the officials. Manifestly, Mr. Price thinks it cannot possibly be to the interest of any Ceylon planter to commit an act which would efface the identity of his estate, and the only possible solution of the matter to his mind is that in order to form breaks of a large size, the purchasers of tea in Colombo endeavour to assimilate the marks throughout their shipment. Mr. Price tells me that he hears of repeated complaints, and of return of teas sent out, to the grocers to whom the members of the wholesale trade have sold them, on the ground that the estate marks do not properly correspond with the description. We must all see that this is likely to cause much injury to the trade, and Mr. Price is most anxious that your Planters' Association should take active steps to check the practice.

TEA IN WYNAAD.

Mr. J. W. Minchin, of Octacamanud, sends us a most interesting *communiqué* aent the pedigree of the tea seed now being planted in Wynaad, which, as he states, is probably unique. We believe that there are some very old tea trees on the Ashambo Hills in South Travancore, and it would be interesting to learn whether their pedigree is similar to those in Wynaad which we surmise is more than likely. Mr. Minchin writes:—

With regards to the high quality of the tea trees in

Wynnad, I have been able to trace the pedigree of the seed bearing trees, and as these have always been entirely segregated, the seed is almost unique, as a pure Assam indigenous tea thoroughly acclimatised in South-India. I find that the original seed was imported from Assam by the then Collector of Salem, Mr. Cockburn, about the year 1820, when the existence of the local indigenous tea plant was first known. The trees from this seed were planted on the Grango Estate at Yercaud and are still thriving, some 20 to 30 feet high; the stem of one is nearly three feet in circumference and a leaf from one of the new shoots measured 10 + 3½ inches.* Col. Scott, of the Veriday Mulla Estate, who has been connected with the planting industry of these hills for very many years, was told of these Assam tea plants by the then Collector of Coimbatore, Mr. Pat Grant, in the year 1862. He was at that time about to plant tea in Wynnad, so visited the Shevareys. The manager of the estate did not know what the grove of high trees was, and was astonished at learning from Col. Scott that they were Assam tea trees. A nursery was formed on the Surrey Estate from the seed obtained at Yercaud, but as the land which Col Scott intended to plant was refused him by Government, who gave him land on the Nigirra at Thai Mulla instead, he removed most of the plants from the Surrey nursery to Thai Mulla, where he planted a large field of this variety of tea, but tells me that he pulled them up, as they differed so much from General Morcao's plants which he ignorantly thought were the only right kind. A few of the plants escaped and were kept up on the Thai Mulla Estate. Meanwhile some of the tea plants were left in the Surrey Estate nursery, and these plants have been growing there since, entirely separated from all other tea, and now, like the original Shevaroy trees, resemble small poplars. Seed from these trees had been planted on the Richmond and Cheria Shola Estates in 1876, and these trees are now seed bearing, and seed from them has been planted on the Glenrock, Wentworth, Richmond, Cheria Shola and other estates during the last few years. As I think this account is of interest, I have sent it to you at length, and as it is now being generally recognised that not only the quantity, but also the quality of the tea depends on the preponderance of Assam jat in the plants cultivated; Wynnad may be congratulated on having a fairly large supply of such good tea for seed.—*Madras Times*, Jan. 4th.

ADVANCES TO CULTIVATORS.

(From the Administration Report of the Bombay Presidency.)

The total amount advanced to cultivators during the year for the purchase of seed and cattle was Rs7,566, and for the purpose of effecting permanent improvements Rs1,27,750 were lent by Government. The corresponding amounts for the year 1889-90 were Rs6,499 and 71,233, and it is therefore clear that moderate terms on which loans are now granted, by Government are gradually attracting the cultivator. In the Northern Division but little advantage was taken of the new takavi rules, but elsewhere, and especially in Sind and the Southern Division, large sums were advanced. From one or two districts it was reported that the rayats held aloof, fearing to take advantage of the chance of borrowing money on easy terms, lest the sarkar should retaliate by declining to advance them money in a bad year when they urgently required it; elsewhere, however, as in Belgauin, the freedom with which cultivators borrowed from Government had the effect of reducing the rates of interest charged by local money-lenders.

* There are tea trees on Abbotsford estate, Ceylon, none of which are more than 17 years old, some of which are over 32 feet in height and 42 inches circumference of stem.—Ed. T. A.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, Jan. 2.

CINCHONA.—The exports of cinchona from Ceylon in October reached the enormous total of 1,079,527 Amsterdam lb. The equivalent of sulphate of quinine in this quantity may be estimated roughly at 760,000 oz.

The following are the exports of cinchona from Java during the periods between July 1st and October 31st (four months):

	1891	1890	1889	1888	1887
	Amster- dam lb.	Amster- dam lb.	Amster- dam lb.	Amster- dam lb.	Amster- dam lb.
Government plantations.....	288,751	264,208	231,410	226,235	238,246
Private plantations.....	3,468,974	2,035,890	1,600,858	1,204,732	1,308,133
Total	3,757,725	2,300,108	1,832,268	1,530,967	1,546,379

QUININE.—There is a perceptible improvement in the market since last week, and sales of 40,000 oz. of German, in second-hand, at 9½d per oz for March-April, and 10,000 oz. of ditto for April delivery are reported. On the spot a parcel of 10,000 oz in second-hand is reported to have been sold at 9½d per oz, but this transaction has not been confirmed. No particular reasons are assigned for this rise of ½d per oz since last week. The influenza, perhaps, has something to do with it, and it is also rumoured that some of the makers are again trying to effect a combination.

AGRICULTURAL VALUE OF SHODDY

The value of shoddy, or woollen waste, as a manure for hops has long been recognised in this country; and in Italy in the crude form of old rags, it is at present largely applied as an economical dressing for olive trees, being pitched in some 3ft. to 4ft. from the stem of the tree. Quite recently, in Ceylon, shoddy (manufactured into a fine powder by treatment with sulphuric acid) has been tried as a manure for the tea plantations; and for these, bearing in mind its richness in organic nitrogen—it promises to prove an excellent fertiliser, if only it be properly applied and of good quality.

Of late years, however, the use of shoddy in Keat has fallen off, probably to a great extent, in consequence of the great variation in the quality of the deliveries. Some lots will contain as much as 30 to 35 per cent. of water, and others show an excess of it and mineral matters, amounting, in some samples, of upwards of 40 per cent.

It may be useful, therefore, in the first place, to give, in the following table, some analyses of the different qualities of shoddy, the results being selected from a great number of samples examined during the past twenty years:

ANALYSES OF SHODDY AND COMPARATIVE VALUE.					
No.	Water.	Organic matter.	Mineral matter.	Ammonia.	Value per ton.
					£ s d
1	10.85	62.00	17.12	8.85	3 6 4
2	25.57	60.33	10.10	8.81	3 6 1
3	20.14	60.48	18.78	8.43	3 3 2
4	25.34	52.78	15.80	8.22	3 1 7
5	19.13	68.60	18.07	8.00	3 0 0
6	14.13	65.10	20.77	7.63	2 17 2
7	17.01	65.20	17.79	7.49	2 16 2
8	21.04	53.57	25.39	6.69	2 9 5
9	18.01	54.71	17.28	6.46	2 8 5
10	25.46	57.35	17.19	6.33	2 7 5
11	3.81	25.91	42.25	3.16	1 3 8
12	32.74	56.21	41.05	3.13	1 3 5

It will be seen from the above results that there is great variation in the composition of shoddy, and that the agricultural value varies with the quality.

It will be noticed that the water varies from 32.74 to 14.13, and the mineral matters from 42.25 to 10.10; while the nitrogenous organic matter—upon which the agricultural value as a manure chiefly depends—varies from 62 to 26 per cent.

The quality of the organic matter further varies—according to its richness in nitrogen—which ultimately becomes converted into ammonia. Consequently, the value of shoddy as a fertiliser may be said to depend upon the richness in ammonia, and the comparative value of the above samples has been accordingly calculated from the proportion of ammonia allowed 7s. 6. per unit. Of course, it will be understood

that in constructing the above table the relative value of the different samples has been stated, because the market value is liable to variation, according to the demand and supply. The above figures are quite sufficient to show the importance of purchasing shoddy upon the basis of analysis—as the ammonia is shown to vary from 8.85 in the best sample to 3.13 in the worst, which is really shoddy dust containing much dirt. The relative value being in the former £3 6 4d. per ton, delivered at station, as against £1 8s. 5d. in the latter. The farmer, therefore, who buys without any analytical guarantee, runs the risk of getting any quality between the above limits.

Shoddy containing from 7 to 8 per cent. of ammonia is a most valuable and economical manure for hops; and it is a pity that it should not be supplied in the natural dry state as it comes from the mills. In addition to the nitrogen compounds, there are mineral constituents of shoddy which have a distinct value as a manure. In the following analysis portions of the residue left after burning were selected in equal quantities from samples 5, 6, 7, and 10. These were carefully mixed, in order to obtain a fair average of the mineral portions.

ANALYSIS OF THE MINERAL MATTERS IN SHODDY.

Lime	8.62
Magnesia28
Potash	1.62
Soda	2.12
Oxide of Iron	11.86
Alumina	2.34
Phosphoric acid82
Sulphuric acid	6.92
Carbonic acid	1.60
Chlorine29
Soluble silica	14.93
Insoluble siliceous matters	48.60

100.00

It will be seen from the above analysis that there is 14.93 per cent. of soluble silica, which forms an important constituent of the flowers and leaves of the hop plant, the flowers (hops) containing in their ashes 19.16 per cent. of silica, the leaves 22.35 and the bines 9.99. There is also 8.62 per cent. of lime, 1.62 of potash, 2.12 of soda, 11.86 of oxides of iron, 6.92 of sulphuric acid, and .82 of phosphoric acid. The value of lime, potash, and phosphoric acid as manurial constituents is fully recognised.

As regards the importance of the presence of a good supply of sulphuric acid, in the form of sulphate of lime, either naturally in the soil upon which hops are to be successfully grown or artificially, as supplied by manure, reference may be made to an interesting lecture on "The Fertility of Hop Soil," given before the Maidstone Farmers' Club in March, 1884, by Mr. F. J. Lloyd, in which special stress was laid upon this point, and the lecturer stated that, in his opinion, woollen rags, on account of their richness in both nitrogen and sulphur, were the most suitable manure for hops.

Lastly, as regards the presence of 11.86 oxide of iron, Dr. A. B. Griffiths, in his book on manures, gives numerous well authenticated experiments, showing increased yield of various crops by the use of iron sulphate in moderate doses; and it is quite reasonable to conclude that hops will also be benefited in a like manner.

Having said so much respecting the fertilising value of the mineral constituents, let us now proceed, with the aid of the above analysis, to calculate the quantities supplied per acre.

It is generally allowed that it takes two tons to properly manure an acre of hops with shoddy. If, therefore we assume that the quality used contains 8 per cent. of ammonia and 17 per cent. of mineral matters, we shall have the following figures.—

TWO TONS OF SHODDY SUPPLY PER ACR.

	lb.		lb.
Ammonia	...	Sulphuric acid	...
Soluble silica	...	Potash	...
Oxide of Iron	...	Phosphoric acid	...
Lime	...		

Let us now compare these figures with those representing farmyard manure. Assuming 1 ton of dung to contain 15 lb. of ammonia, 12 lb. of potash, and 7 lb. of phosphoric acid, it would require, in round numbers, 24 tons of good dung to yield the 358 lb. of ammonia supplied by 2 tons of shoddy.

The 24 tons of dung would certainly also supply 288 lb. potash and 168 lb. phosphoric acid; but both these constituents should be largely supplied naturally by a good hop soil, whereas the ammonia has to be provided by the farmer. This being so, it is necessary to regard the cheapest source of ammonia as of the greatest importance. Farmyard manure, or London dung delivered, would cost about 7s. 6d. per ton, consequently 24 tons would represent £9, as against 2 tons shoddy costing £6, which leaves a saving of £3 in favour of using shoddy against farmyard manure. When the farm is situated a considerable distance from the station, the smaller bulk of shoddy compared with dung would, of course, make the above comparison still more in favour of the former. Shoddy, like dung, is a slowly decomposing manure, and should be carted on during the winter months, and carefully dug in round the hop-hills, where under favourable climatic conditions, it should afford a continuous source of nitrogenous plant food as required, and in this respect forms a marked contrast to those concentrated and highly soluble fertilisers, such as dissolved guano and nitrate of soda, which, in the more advanced and often critical stages of growth, have been found to render special assistance when judiciously employed. In conclusion, it may be well to mention that, in analysing samples of shoddy, it is most necessary to make a water determination in the material as received, and then proceed to cut up a portion for the nitrogen determination, taking care to make a second water ditto in finely cut-up portion, which, on account of water lost during the process of cutting up in a warm room, is naturally much drier, and therefore richer in nitrogen, than the shoddy as originally received. The nitrogen results being calculated eventually upon the natural wet state of the shoddy as received, will represent the real quality of the material.

If farmers will take the trouble to stipulate that the shoddy shall contain from 7 to 8 per cent. of ammonia (and be in a fairly dry condition, containing not more than 20 per cent. of water) they will find it one of the most economical manures that can be purchased. Indeed, manure manufacturers—many of them—have good shoddy with marked advantage in compounding special mixtures, where nitrogen, in the form of organic matter is required. Further than this, several patents have been taken out for the purpose of treating shoddy with sulphuric acid, and, by subsequent drying, to convert the bulky material into a fine powder which can readily be passed through a drill.

For vines, as well as for shrubs like tea, coffee, cacao, and the numerous garden fruit trees, shoddy is admirably adapted; and it is hoped that the remarks that have been made in reference to its use for hops will attract attention to the more extended application of a manure which, at the present time, is certainly so suitable and so cheap.

JOHN HUGHES, F. C. S., Consulting Chemist to the
Ceylon Planters' Association.
79, Mark-lane, E. O.
—Field.

PHARMACEUTICAL ETYMOLOGY.

The following notes are gathered from the most recently published volume of the Philological Society's new English Dictionary, edited by Dr. Murray.

There are several "Cloves" of distinct origin. The term as applied to the spice, the dried flower-bud of *Caryophyllus aromaticus*, is derived from the French *clou*, which word was originally applied to it on account of its shape. The *Caryophyllus* is the Latinised form of the Greek term derived from *karyon*, nut, and *phyllos* leaf. In old French the spice was termed *clou de girofle*. This term passed on to the clove-scented pink (*Dianthus caryophyllus*), but *girofle* has passed into English as gilly-flower, and represents others

scented flowers. Some very correct people with inaccurate ideas of its etymology have civilised gillyflower into "July flower."

The "clove" of garlic, &c. is traceable to the old Teutonic words which give us cleave, clove, cleft, and is applied on account of the separated condition of the fruit.

How "clove," an old weight of wool and cheese (=about 7 or 8 lb. avoirdupois), came to be adopted is not known. It is understood to be derived from the Latin *clavus*, a nail, which was also under that name a lineal measure in olden time. The connection between the nail (measure) and the clove (weight) seems to be lost.

Coca is the Spanish form of the Peruvian *Cuca*. Its first mention in English literature is found in Ballokar in 1616.

COCCULUS (as in *Cocculus Indicus*) is morely a Latin word signifying a little berry.

COCHINEAL comes via the Spanish *cochinilla* from the Italian *cocciniglia*, traceable to the Latin *coccineus* scarlet coloured. In Spanish the same word, a diminutive of *cochina*, now, is used as the name of the wood-louse, and has been suggested as the origin of cochineal. But the two words appear to be only fortuitously similar and have entirely distinct origins.

Cocoa and COCOA NUT have occasioned no end of confusion among un-instructed people. COCOA (the "grateful and comforting" article obtained from the seeds of the *Theobroma cacao*) is a corruption of the three-syllabled word "caca-o," which was the Spanish adaptation of the Mexican name for the seeds *cacawitl*. The coco-nut was, and should be still, written "coco." It was so called by the Portuguese when they discovered it in India, where it was called in the native language *tengna* or *tenga*. COCO is a Portuguese word for grin or grimace, and was probably used in reference to the queer-face-like appearance of the hase of the shell with its three holes.* It is worthy of note that in Johnson's Dictionary the article "Coco" was run together with that on "Cocoa," apparently by an accident, for Johnson himself used the word "Coco" (plur. Cocos) in his other writings. This accident is probably to some extent the cause of the confusion which has prevailed between the two words.

COFFEE is the descendant of a Turkish word *qahwah*, which was applied not to the berry but to the beverage, and is believed to have originally meant some sort of wine, and to have been derived from a verb which meant to have no appetite.

COMMERCE began to be substituted for "merchandise" in the latter part of the sixteenth century. It is composed of *com*, with, and *merc*, *merci*, wares. For more than a century the word was accented on the second syllable, as in Watts's line (1709), "I held no more commerce with Hell."

COMPETE and COMPETITOR are among those words of which the original sense has been modified by human tendencies. The etymological meaning, and no doubt the early use of the words, implied a seeking in company, a sort of partnership. The union develops into rivalry, the rivalry into opposition, which is more like the modern signification.

CONCOU, as applied to tea, is a corruption of the Chinese word *Kung-fu*, work. It means tea on which work or labour has been expended.—*Chemist and Druggist*, Dec. 26.

THE CEYLON LAND AND PRODUCE COMPANY, LIMITED.

Report of the Directors to be submitted to the Seventh Annual General Meeting of Shareholders to be held in Room 147 (1st Floor), Leadenhall House, 101, Leadenhall street, in the City of London, on the 31st day of December, 1891, at 12 o'clock noon.

Your Directors beg to submit the annexed profit and loss account and balance sheet for the year ending 30th June, 1891, duly audited.

The amount at credit of profit and loss account, after deducting depreciation of machinery and buildings on New Peradeniya, Fetteresso, and Rickarton estates

(1,000), and writing off £8,038 10s 8d from the Matale properties referred to below, is £3,069 6s 6d which with the sum brought forward from last year £2,308 7s 4d leaves, £5,377 13s 10d to be dealt with.

Your Directors propose to pay on the 30th day of January, 1892, the fixed Cumulative dividend of 6 per cent on the preference shares, and 10 per cent on the ordinary shares, both less income tax, and to carry forward the balance, £1,693 3s 10d subject to the Directors' remuneration for the year under review, to be fixed at the general meeting, and to the payment of income tax.

Your Directors' earnest consideration has been given to the question of the capital value of the Matale Estates as they stand in the books. In the report for year ending 30th June, 1889, it was stated by your then directors that the expectations on which the Company's Cocoa Estates were acquired had not up to that time been fulfilled, and in the amended report for same period your Board expressed the belief that that was partly owing to the unprecedented drought that occurred early in the history of this Company. They have now, however, come to the conclusion that a shrinkage has occurred in their original value, and they consider this to be an extremely favourable opportunity for re-arranging the figures. They have therefore written off from profits the sum of £8,038 10s 8d, and applied the same in reduction of the book values of the Matale Estates. In effecting this reduction your Directors anticipate the shareholders' co-operation and consent.

The past year has been a favourable one for the Company, the satisfactory result of which is largely owing to the exceptionally high prices which prevailed and were obtained both for cocoa and coffee.

It is gratifying to your Directors to report that the average prices for Ceylon cocoa during the year have been on a higher scale than formerly and when the curing has been carefully attended to, extreme values have been obtained; the production, however, in the island does not appear to extend very rapidly.

A new feature however has been developed, in the increased output of Java since 1886, during the last two years particularly so, and the rapid strides made in the improved curing has made this growth a strong competitor which your Directors think will be felt. The demand continues good, and it is noteworthy that no stock of Ceylon is on hand, proceeds going immediately into consumption after sale, which of course adds strength to the position.

With regard to coffee it is pleasing to your Directors that they can report that prices during the whole of the year have been of an eminently satisfactory character. The prices for the article have continued high since 1886, and although consumption does not appear to have been materially affected, the production has been stimulated, and the world's supply will probably be considerably increased in the near future. Your Directors therefore anticipate a lower range of prices, but they look forward with confidence, that those for Ceylon will be still remunerative.

The Company's Teas have also shown a profitable result, but your Directors view with some concern, and indeed it has been pointed out by various authorities, that the planting of this product is being overdone in Ceylon; they have therefore instructed the Company's Managers to cease planting tea on any extensive scale, and have directed them to give their attention to the introduction of coffee, cocoa, and other and minor products on any of the Company's land suitable for their growth.

The year 1891 opened with a strong market for Ceylon tea, the average price at the public sales in January being 11½ per lb. No material decline took place until April when arrivals increased, and in consequence of unusually heavy flushes, the quality showed a marked falling off, while, in many cases, the dry leaf evidenced hurried preparation. Mainly owing to these causes prices became weaker, and the general average for the past six months to the end of November has ruled at about 9½d per lb. Lower rates have, however, no doubt benefited the industry

THE CEYLON TOBACCO COMPANY LIMITED.

It is only right that all the circumstances connected with the enterprise so named should be known. The main point is that the bulk of the capital of the Company was invested in land, which cost some R81,000, or nearly half the capital of the Company, which was about R220,000. When after two years' experience tobacco was found to be not only uncertain in growth, but also difficult of sale, it was decided at once to open with other products; and had the shareholders all paid their calls, the directors would have been able to go on for another 18 months, by which time 120 acres of tea would have been in partial bearing, and the cacao, Liberian coffee, and coconuts so advanced as to render it easy to finance the Company. The money was not by any means all spent. When it was decided to voluntarily wind up, the assets were some R25,000 of unpaid calls, or rather more than the equivalent of a year's working; and some 60,000 lb. of tobacco, which it is hoped will realize at least 20 cents per pound average. So far, we believe, none has fetched less than 27 cents, but it can only be sold in small quantities, say R12,000 as the value of the tobacco. In addition to this the Company has all its lands, which are some of the finest in Ceylon. Of course all concerned knew that tobacco was a great speculation and that the Company have lost on it goes without saying; but it is contended that the directors did the best they could in the interest of the Company in commencing to plant other products with a view to selling the properties. Messrs. T. N. Christie, Armstrong, Owen, Hill, &c. were all shrewd, hard-working honest men doing their best without pay or remuneration for the Company as directors; and the fact that at a large meeting two of the directors were unanimously (with the exception of Mr. Borron, who left the room) put on the consulting board to assist the Liquidator shows that they still retain the confidence of the shareholders. It gives us much pleasure on public as well as private grounds to state these facts; and we shall be only too glad to learn that the valuable lands and cultivation possessed by the Company will realize prices which may enable the accounts to be closed without loss to any of the shareholders. It was really the refusal of so many of these to pay their calls, we believe, which compelled the directors to decide on liquidation.

LAST WEEK ON PRODUCE AND FINANCE.

DARJEELING TEA—Messrs. Lloyd and Carter report that auctions have been lighter during the past month, and this, coupled with a very low range of prices, has enabled buyers to operate with more confidence, and all grades have been taken at a slight advance. The deliveries and stocks can hardly be considered satisfactory, but with continued low quotations, there should be increased consumption. The best averages have been made by M L B over M K in cross Poohong Goomtee, Selimbong and Hope Town, but some very choice teas have been sold from Oh-mong; the Orange Pekoe at 3s 7d, Broken Orange Pekoe at 3s 11d, and P. koe at 2s 4d.

LAST WEEK'S TEA SALES.—On Monday the public sales of Indian tea, says the *Grocer*, amounted to 20,520 packages, when notwithstanding the foggy weather and the near approach of the holidays, there was a steady demand, and the above quantity was taken off at full rates, especially for the best liquoring kinds. Ceylon Tea.—A very dense smoke and fog enveloped the City on Tuesday, when 10,450 packages of Ceylon tea were offered, but the demand proved good, and full prices were obtained. An occasional irregularity was apparent, while the small breaks were

extremely slow sale. Sales will now be suspended until the New Year, and the trade will be heartily glad of the interval, as the number of samples tasted for months past has been remarkable.

"A RANK AND ASTRINGENT DECEPTION."—In a book entitled "Delicate Dining," Mr. Theodore Child, the well-known American writer, says:—"In a great country like England it is impossible to obtain really well-made coffee, except in a few private houses, while English tea is generally a rank and astringent decoction, instead of a delicate infusion." This may be true; but, at least, we have the consolation that in the matter of tea-making we can give Mr. Child's countrymen and women some points. But we Westerns have much to learn from the Chinese and Japanese as to the art of infusing tea. If the British matron and her family were to drink tea as often as the light-hearted Japanese do, the result would not be conducive to the comfort of the said matron and family. To materially increase the consumption of tea some method of infusion akin to the Eastern is necessary. Mr. Child is right. Stewed tea is a "rank and astringent decoction." Let us, by all means, adopt a better method of infusing, and tea may be taken at all times without injury. It is not urged against the Japanese or the Chinese that they take too much tea, and yet they are for ever drinking it. They are not accused of being victims to dyspepsia either; and when our learned physicians wish to point a moral they do not go to the Far East, but maintain that we who drink tea far less frequently than the peoples of China and Japan are ruining our digestions in consequence. One would almost think that scientific opinion, far from being on the side of the angels, was on the side of the brewers.

THE ADULTERATION RECORD.—The record of the year's adulteration with the London area shows that tea is the only article of produce which has a clean bill of health. Coffee continues to be adulterated freely. Chicory is invariably the foreign substance, and the proportion used is often enormous. The cocoa drinkers will not appreciate the fact that their favourite beverage is the chief subject of adulteration, no less than a third of the ninety-six samples analysed having been condemned. In many instances the amount of sugar, starch, and arrowroot added was so considerable that the nutritive value of the quantity of cocoa used for making a cupful must be infinitesimal. After a good many years, in which the adulteration of sugar had apparently ceased, it has again come under notice in a curious form. Of 246 samples examined, nearly one-seventh were reported as having been coloured with an aniline dye in an acober tint in order to make white crystals of beet sugar imitate the more valuable Demerara. The quantity of the dye used, however, is very minute. The following figures show the number of samples examined during the year, and the percentage of cases in which adulteration was reported:—Coffee, 1,733; adulterated, 266; percentage in 1889, 14.9; ditto, 1890, 15.3. Sugar, 246 adulterated, 34; percentage in 1890, 13.8. Pepper, 1,329; adulterated, 75; percentage in 1889, 8.9; ditto 1890, 5.6. Tea, 349; adulterated, 0; percentage in 1889, 0.5; ditto, 1890, 0.

BANANA CULTIVATION.—Discussing the banana, the *Horticultural Times* says:—"At present the fine-flavoured bananas are almost unknown in Europe; not because their excellence is unappreciated, but simply because the fruit is of necessity too long by the way to reach those countries in a marketable condition. So it comes that two lines of inventions having to do with banana culture are sorely needed in the West Indies, where with them the banana output would soon be doubled, and in time might easily be multiplied tenfold. These are a desiccating process and a flour of meal-making process. The former is at present most in demand, and wherever one travels in the banana-producing regions, from Demerara to British Honduras, from Colon to Samana Bay, the cry will be heard at every large plantation, "Oh! if someone would only invent and perfect a drying or preserving process that could be depended on." The man or men who can

put before the banana-growers of the West Indies who send thousands of pounds worth of this fruit to England each year, any system which will do for the banana what is now done for the fig, the grape, or the corinth, commonly known as "dried currants," or who can succeed in treating that fruit as well as peaches, apricots, and prunellas now are, will find himself the possessor of a wealth-producing invention. And the same may be safely predicted of any system which will succeed in putting into the meal or flour state a fair portion of the marvellous sustaining and nourishing powers which makes the banana the king among fruits. The improvements which this century has seen, that lead up from the rude maodica meal of the Brazilian native to the beautiful pearl tapioca of commerce, have developed for the cassava, *Manihot utilisima*, a foreign consumption which now runs high into the millions of dollars annually. The same period has seen the crude black cacao of the Carribbees and northern South America develop into the chocolate, breakfast cocoa, and bronca of today, and now the tree *Theobroma cacao* vies with coffee in yielding nourishment and producing wealth in many countries. So may it be with the banana, if inventive skill will but turn its attention in that direction.—*H. and C. Mail*, Jan. 1.

THE TAMBRACHERY ESTATES COMPANY.

The tenth annual meeting of the shareholders of the above company was held on Monday at the Cannon Street Hotel E. C. Mr. James Labouchere in the chair. The notice convening the meeting having been read.

The Chairman submitted the report for adoption. The directors reported that the profit and loss account showed a loss on the season's working of £3,166 11s 10d and after deducting the amount brought forward from the previous year, £1,147 12s 4d the balance carried forward to the present year's account is £2,016 19s 6d. The expenditure of the season showed a considerable diminution on that of the previous year, and the abandonment of unprofitable land and the reduction of staff would enable the current season's outlay to be further reduced to about £5,000. The London expenses would also be considerably reduced. The directors regretted that their appeal for the subscription of debentures resulted in applications for £1,600 only, and as it was absolutely necessary to pay off the balance of loan, £1,750, secured by the Nelimunda Estate, now the most valuable estate of the company, their trusted shareholders would at once, in their own interest, come forward with further subscriptions, and thereby enable this estate to be included in the security for the debentures. To furnish also a little working capital, which is imperatively required, a further sum of £3,400 should be subscribed, and the directors would be glad to receive applications. The hopes of the directors, based at the time upon actual results, that the entire capital of company would by this time have been in course of rapid redemption by the proceeds of bark alone, had been utterly falsified by the excessive production of Ceylon and latterly Java, and there appeared to be little hope of improvement in prices until supplies showed a material falling off. This was generally expected to be the case in two or three years, and the directors were therefore anxious to keep up the planting of cinchonas, particularly Ledgerianas, as far as means would allow, in order to have a reserve in hand when needed. It was important to utilise some of the spare land of the company with a view to profit, most of it being suitable for tea. The success obtained in Ceylon and Travancore by planting old coffee estates with tea, offered every inducement to extend its cultivation in Wynaad, and the directors hoped early in the coming year to be in a position to place a definite scheme before the shareholders. The season in Southern India has again been one of abnormal weather. To this cause must be attributed some injury to the present crop of coffee by heavy rains in July and September. The first estimate of

70 tons would not be realised, and the directors could only hope for 60 to 65 tons, and about 135,000 lb. bark. The coffee had been sold for arrival at 94s. per cwt. landed terms, and at this price should more than cover the outlay of the year, leaving the bark available against the deficit brought forward.

The motion for adoption having been seconded by Mr. H. Tolpitt, it was agreed to, and the proceedings terminated with the usual vote of thanks.—*H. and C. Mail*, Jan. 1.

USEFUL FOR HOUSEKEEPERS.

TABLE OF MEASURES.

Two pepper spoonfuls make one salt spoonful.
Two salt spoonfuls one coffee spoonful.
Three teaspoonfuls one tablespoonful.
Four tablespoonfuls one wine glass.
Two wine glassfuls one gill.
Two gills one cupful.
Two cupfuls one pint.
Twenty-five drops of liquid make one teaspoonful.
One tablespoonful of salt one ounce.
One teaspoonful (heaping) of brown or granulated sugar one ounce.
Two tablespoonfuls of powdered sugar one ounce.—*Florida Agriculturist*.

The jarrah wood of Western Australia has lately been coming into great favour in Europe, principally for street paving purposes. Jarrah is a good wood as hard and durable as oak, and it will be found of use in other ways than for the laying of streets. It has a deep rich colour, something like mahogany or very old oak, and is very suited for carving and panelling. There is only one other wood at the Antipodes which is superior to it—the Fijian *resti*, but this is comparatively scarce and hard to get at. It grows abundantly enough in the thick forests on the large island of Vanua Levu.—*Colonies and India*, Dec. 26th.

WINDING UP OF THE CEYLON TOBACCO COMPANY, (LTD.): "ENDING IN SMOKE"?—As a sombre contrast to the bright and cheerful reports of the various Ceylon tea companies published from time to time, the report of the [un] "happy despatch" of the tobacco company is startling. Personally we are no believer in tobacco culture: we object to fertile soil being rendered barren that men may puff smoke in their neighbours' faces and taint the pure air of heaven. We cannot affect grief, therefore, at the collapse of the attempt to grow the narcotic on a large scale. But really it was not grown on a large scale; its cultivation according to the figures being so small in proportion to tea and other products that the name of Tobacco Company seems inappropriate. Coconuts, Liberian coffee, tea and cacao preponderated; and with so much cultivation and so much valuable land, the mismanagement which has ended in the necessity of winding up must on the part of the Manager or the Directors or both have been lamentable and discreditable. The case is a disgrace to the colony and calculated to injure its interests. The blame therefore ought to be definitely fixed on some person or persons, and not left to be vaguely inferred. Mr. Borrer's absurd theory, that Directors can be personally estimable and yet blamable for such discreditable consequences as have resulted from what ought (tobacco out of the question) to have been a successful enterprise, will not be accepted. Did Mr. Ingleton do justice to the interests entrusted to him? If not what surveillance did the Directors exercise? In view of the extraordinary report, people will be sure to ask such questions.

ELECTRICITY AS A POWER FOR CEYLON
TEA FACTORIES.

More than six months ago we penned and sent into types some interesting information we had received regarding a project for the employment of electricity on Mariawatts estate. At the special request of the gentleman from whom we had received the information we suppressed our notice, as the matter was and we believe still is only under consideration. As usually happens in such cases, the local "Times" gives to the world the information we were requested not to publish. Requests to abstain from publicity do not go for much with our contemporary. The truth is, that in planting circles the fact of the proprietors of Mariawatte contemplating the transmission of electric power generated by water at a distant portion of the property to the factory has been no secret. The expedient of removing the factory, where steam is now used, to the locality where water power is abundant was precluded, we believe, by the nature of the building, a large and ponderous iron structure. As the transmission of power was estimated to cost at least £1,000, we do not wonder at hesitation. It happens, also, that with reference to a property in which we are interested, the question of the transmission of power from the lower portion of the estate where water was abundant to the higher where for three months of the year water was scarce, became a practical and urgent one. The factory was built at the top of the estate when only a subsidiary tea cultivation was contemplated,—when most planters cherished the hope of the survival and revival of coffee. Transmission of power upwards by electricity and by belting, after consideration, abandoned as too expensive, and the factory is to be moved down to the spot where water power is abundant. The question is mainly one of comparative expense and efficiency: the factory in this case is not an iron one, and the lower position is the better in all respects. The time is at hand, however, we believe, when electricity will be so cheapened as to be largely available as a motive force and in the transmission of power.

THE CEYLON TOBACCO CO, LTD.

GENERAL MEETING.

Minutes of proceedings of an extraordinary general meeting of the shareholders of the Ceylon Tobacco Company, Limited, held on Saturday, the 28th day of November 1891, within the registered office of the Company, No. 42, King Street, Kandy, at 3 o'clock p.m., in the afternoon.

BUSINESS.

To consider the following resolution:—"That the Ceylon Tobacco Company Ltd. be wound up voluntarily;" to appoint Liquidator or Liquidators; to decide on the remuneration to be paid to such Liquidator or Liquidators; and to appoint a person or persons to inspect the Liquidators' accounts. The shareholders present were: Mr. C. S. Armstrong, Chairman of the Board of Directors, who presided, Messrs. A. P. Crawley-Bocvey, G. A. Talbot, D. Reid by his attorney G. A. Talbot, A. G. K. Borron, A. Van Starrex, J. Emerson, R. E. Waller, T. C. Huxley, D. Fairweather by his attorney J. R. Fairweather, Alexander Tait, A. C. Bonner, W. Megginson, T. N. Orchard, H. Drummond Deane, James R. Fairweather, Hugh Fraser, A. Philip (Secretary of the Company).

The following gentlemen held proxies for shareholders absent:—Mr. A. Fraser for Messrs. W. H. L. Murray-Menzies and Alexander Seton, Mr. C. S. Armstrong for Messrs. P. E. Radley, James Hill and William Forbes Laurie, Mr. A. Philip for Messrs. James Bisset, Henry James Vollar, George Wall,

E. Dick, and Norman Wm. Grieve, Mr. H. H. D. Deane for Messrs. T. N. Christie, J. Mao Donald Murdoch and C. Minto Gwatkin, Mr. G. A. Talbot for Mr. H. K. Rutherford, Mr. J. H. Spronle for Mr. Frederick Dornhorst, Mr. A. G. K. Borron for Mr. Jas. H. Barber and Mr. J. W. Vanderstraeten, Mr. A. Tait for Mr. H. W. Ashby and Mr. G. D. Moir, and Mr. W. Megginson for Mr. S. L. Harries. The notice calling the meeting was read. The minutes of proceedings of the annual general meeting of the Shareholders held at Kandy, on the 17th day of April 1891, were read and were confirmed.

The CHAIRMAN, Mr. C. S. Armstrong, then spoke as follows in moving the first resolution, viz:—"That the Ceylon Tobacco Company, Limited, be wound-up voluntarily." The Company was originally initiated in Jan. 1889, by Messrs. H. Fraser and Rutherford. It will be remembered that it was arranged at a meeting of the promoters of the Company held on the 19th January 1889, operations should be begun on Bandarapolla estate at once under Mr. Fraser's management. Shortly after Mr. Fraser's departure to England the land at Bandarapolla was visited by Mr. Vollar and pronounced to be unsuitable for tobacco and the nurseries a failure. Your directors consider it is unnecessary here to recapitulate the steps that led to the final abandonment of the operations on Bandarapolla clearing, but would refer you to the statement of facts by both parties dated 22nd November 1890, and the agreement on behalf of the Company also the award by the arbitrators dated May 1891, together with the account resulting in an unforeseen loss of about R3,000. In the meantime the Company had arranged with Mr. Holleway to purchase lands in the vicinity of Ukulle, Wategama and Katugastota with the following results:

	A.	R.	P.
The Ratwatto estate	..	314	3 10
Lands between Katugastota and Wategama and adjacent to Mr. Vollar's Mugama estate viz. Polgolla	..	57	3 09
Narangdando	..	31	2 24
Goonapana	..	23	2 06
Meolgama	..	8	0 20
		121	0 39
Land at Harrispatu near the road to Galegedera known as Oolanapita	..	43	1 31
also two small blocks known as Kengalle and Bocalawello	..	4	3 27
		2	1 30
		7	1 17

Lands at Dorakumbura now comprised in the Matale estate. ... 128 3 09

There is land purchasable and already negotiated for in the neighbourhood of each of these lots which would bring any of them up to a workable acreage and the further purchases of lands in the neighbourhood was stopped when the amalgamation of Mr. Fritz Meyer's interest with this Company was arranged for. The cost of these lands to the Company is R28,276-57. The lands were inspected by your directors and approved, and they consider them most admirably adapted for cultivation of either cacao, tea or Liberian coffee.

On the 13th January 1890 your directors favorably entertained a proposal from Mr. Fritz Meyer by his representative in Ceylon Mr. Schappe to acquire his several properties at a cost of R50,275-36 of which R47,600 were taken up in shares in the Company, the lands were as follows:—

	A.	R.	P.
Meegama adjoining Mr. Vollar's Meegama	...	88	0 0
Katugastota lands	...	123	3 11
Davie's Ferry	...	93	0 0
Lewelle	...	57	0 0
Ukulle	...	74	2 36
		409	2 07

Dorakumbura (Matale estate)	144	3	31
which with the 28a. 3r. 09 purchased by Mr. Holloway comprised the Matale estate Kurunegala lands.			
Arapolla Estate...	...	505	0 0
Forest Black	168	0 0
Dugama Forest	71	0 0
		747	0 0

It will be seen from the above the acreage now owned by the company is A1,917-0-24 costing R78,551-93 besides which R3,819-85 stands at the debit of Mr. Holloway for lands advanced against for purchase.

Your lands under cultivation are as follows:—

Matale Estate.—Tea	40
Cocoa	167
Liberian among cocoa...	...	20
Tobacco "..."	...	37
Ratwatto Estate.—Tea	100
Ready for planting	20
Arapolla Estate.—Cocoons	263
Coconuts to be planted by November 20		
Liberian coffee among coconuts...	175	
Cleared	65

And I lay before you the Manager's report up to the 26th inst. Your Directors consider you at this date hold most valuable property and lands. The estate expenditure on the three properties Matale, Ratwatto and Arapolla amounts to R98,111-88 up to the 31st October current, of this R51,086-98 were expended this year.

Your Chairman and the Directors who were elected by you at the general meeting of the 17th April 1891 visited the estates and all other lands in May and June, they found the new cleared lands and the cultivated portions in a much neglected condition they at once communicated with the absent Directors in England and the then Manager Mr. J. K. Ingleton. Meanwhile it is manifestly advisable that the estates on which so much money had already been expended should be properly planted up large nurseries for the various products being then existent. Your Directors having every reason to hope for a large accession of funds by the sale of the tobacco crops a portion of which was to have been sent to Messrs. Gibbs, Bright & Co. at Melbourne who wrote on the 27th January 1891 as follows:—

"The 16 bales intended for the Melbourne market was sent to Colombo in July but no freight could be found for them, the shipping agents declining to take tobacco considering that it would taint the Ceylon tea shipped by them."

Every effort has been made to dispose of the tobacco crop with but little success, only 2,036 lb having been sold at this date. The crop for 1890 is 48,932 lb., that harvested for 1891 is estimated at 10,000 lb. with the sucker crop to follow or say about 6 or 7 tons in all.

On the 2nd of September your Chairman addressed the absent Directors through Mr. Christie putting before them what they considered the exact position of things with a view of endeavouring to finance the company at Home. At the Board meeting held on the 28th October it was found that the amount of unpaid calls overdue were but little altered for the better, this coupled with the uncertainty as to when the tobacco crop might be realized, and a definite reply showing the improbability of being able to finance this company at Home having been received determined the Directors in your interest in at once arranging for the extraordinary General meeting of today to consider the formal resolutions which are to be put before you and we still consider the course we advise to be the best in the interest of the company.

The expenditure as from the 1st December need be but small as the only work necessary will be the weeding of the clearings and the salary of the manager Mr. Kingsford who we considered advisable to retain till the end of December, having dispensed with the services of the two assistants on the 1st December. The amount available in the Bank at November is R5,413, and the funds necessary to carry on to the end of December would be about R6,000, should the estate be carried on for 1892 under Mr. Kingsford's careful supervision with two conductors to assist him. The estimated cost of upkeep is

R25,000 and for 1893 of R20,000, and say contingencies R10,000, when 160 acres of tea would be in partial bearing. But though this amount would be sufficient for the carrying on of the existing cultivation, to make Ratwatto Estate a self supporting estate a further sum should be allowed for opening and bringing another 100 acres of tea into bearing. At first sight it would seem there should be no difficulty in raising the loan necessary for this purpose, but bearing in mind the long period before crops can be secured that will pay a dividend it will be understood that it is next to impossible to effect this. Your directors having carefully considered the questions from all points think that voluntary winding up by a Liquidator assisted by a consulting Board to help him in disposing of the company's lands would be the best course in the interest of the shareholders who will in that case probably get a considerable return of their money.

The CHAIRMAN then moved:—"That the Ceylon Tobacco Company, Limited, be wound up voluntarily."

Mr. G. A. TALBOT seconded the resolution proposed by the Chairman remarking that the owners of Sumatra estates are ruined and that Ceylon was not peculiar in failure to grow tobacco remuneratively. The shareholders must therefore suffer; other products had unfortunately failed too and he was disposed to blame the directors and managers as in his opinion the property had not been properly managed. He supported the resolution to "wind up." It was possible that there was sufficient money to carry on for another year. There was a better chance by adopting the resolution and have the properties put on the market; further the resolution is the decision of the Board.

Mr. A. G. K. BORRON criticised the management of the Company and as a shareholder he was indignant. The Directors individually were entitled to respect but he considered the directors in this matter ignorant, imprudent and that he would rather pay 60 per cent into the sea. Sharebrokers in Colombo stated that the shares were not worth a cent. Mr. Borron proposed the following amendment:—"That a Committee of investigation be appointed to examine the books, papers, &c., of the Company, to visit and report on the properties of the Company, and generally consider the position and prospects of the Company and to advise the Company as to the best course at an early general meeting of the Company."

Mr. A. TALBOT seconded the amendment.

Mr. HUGH FRASER spoke in explanation of his relations to the Company alluded to by the Chairman.

Mr. T. C. HUXLEY supported the resolution.

Mr. H. D. DEANE defended the absent directors. The directors had taken a great deal of trouble and had conscientiously carried out their duties.

Mr. W. MEGGINSON asked for some figures as to the defaulting shareholders. The Chairman accordingly gave particulars of the defaulting shareholders.

Mr. J. R. FAIRWEATHER as one of the defaulting shareholders stated that the sole reason for non-payment of calls was simply on account of the gross mismanagement of the Company; he spoke on behalf of his brother and himself. On the amendment and resolution being put to the meeting the resolution was declared carried. A poll having been demanded, Messrs. G. A. Talbot and A. G. K. Borron were then appointed tellers for the amendment and resolution respectively with the following result:—

For the amendment .. 7 votes.

For the resolution .. 134 "

Resolutions I and II were proposed by Mr. G. A. TALBOT, seconded by Mr. A. P. CRAWLEY-BOEVEY and unanimously carried as follows:—"That Mr. A. Philip be appointed Liquidator," and "That the Liquidator be paid a commission of 5 per cent on all monies recovered by him as Liquidator for the credit of the Company and be entitled to charge against the assets of the Company all expenses, costs and charges of the winding up."

Resolution III was proposed by Mr. T. C. HUXLEY seconded by Mr. T. N. OUCHARD and unanimously carried as follows:—"That Messrs. Armstrong, Doane, Huxley, J. R. Fairweather and A. C. Kingsford be requested to assist the Liquidator in disposing of the

effects of the Company." Before the above Resolution was put to the meeting Messrs. Deane and Armstrong declined to serve unless they were unanimously elected.

Resolution IV. was proposed by Mr. G. A. TALBOT, seconded by Mr. A. P. CRAWLEY-BOEVEY. :—"That Mr. J. Guthrie be appointed to inspect the Liquidator's accounts."

The meeting of the shareholders then dispersed. Confirmed at Kandy this 15th day of January 1892.

(Signed) C. SPEARMAN ARMSTRONG,
Chairman.

Minutes of proceedings of an extraordinary general meeting of the shareholders of the Ceylon Tobacco Company Limited "held within the registered office No. 42 King Street, Kandy, on Friday, the 15th day of January 1892, at 3 o'clock in the afternoon.

BUSINESS.

To confirm the following special resolution passed at the extraordinary meeting held on November 28th last at the Company's registered office viz :—"That the Ceylon Tobacco Company Limited, be wound up voluntarily." The shareholders present were Mr. C. S. Armstrong, Chairman of the Board of Directors, who presided Messrs. T. C. Huxley, R. H. E. Walker, H. D. Deane, J. R. Fairweather, A. Phipp (Secretary of the Company).

The notice calling the meeting was read.

The minutes of proceedings of the Extraordinary general meeting of shareholders held on Saturday the 28th day of November 1891 were read and were confirmed. Read letters from Messrs. Volkart Brothers.

The following gentlemen held proxies for shareholders absent :—Mr. A. Philip, for Messrs. H. J. Vollar, F. G. Bewes, J. T. Emerson, Alexander Tait, George Wall, James Bisset, Mrs. Edith Dick, Messrs. A. P. Crawley-Boovey, W. Megginson, E. H. Hutchinson, J. M. Murdoch, Hugh Fraser, Mrs. A. P. Boustead, Messrs. Thomas North Christie, David Reid, H. K. Rutherford, T. N. Orchard, T. C. Owen, Norman W. Grieco, W. Mills and S. L. Harries; Mr. C. S. Armstrong for Mr. P. E. Radley; Mr. H. D. Deane for Mr. C. Minto Gwatkin.

Resolution proposed by Mr. C. S. Armstrong, seconded by Mr. T. C. Huxley, and unanimously carried: "That the following special resolution passed at the extraordinary general meeting held on Nov. 28th last at the Company's Registered Office, viz.: That the Ceylon Tobacco Company Limited be wound up voluntarily be and the same is hereby confirmed,

The meeting thereafter dispersed."

A. PHILIP, Secretary.

A MERCARA correspondent writes to a contemporary :—"Coffee selling at R14'8 a bushel, delivered on the estate! No wonder we are all in such high spirits. Such crops and such prices have not been experienced for years! A happy New Year indeed!"—*Madras Mail.*

COFFEE AND TEA IN JAVA.—The estimate of the Government's coffee crop on Java is, according to a telegram, 395,194 piculs. The latest reports regarding the weather in Java are favourable for the coffee cultivation. The outturn of the crop will be generally equal to the preceding one, and especially in Malay, the crop will be large. Other produce, such as sugar, tobacco, indigo, and tea, which require plenty of rain, have suffered much from the excessive drought, which has prevailed in Java.—*L. and C. Express, Jan. 1st.*

THE SUPPER UNCERTAINTY OF THINGS in regard to the Australian pastoral and agricultural industries is being remarkably illustrated just now. A few months ago Queensland was in the darkest depths of depression. Drought, as usual, was the primal cause. Heavy and universal rains however, arrived just in the nick of time, and now the wool clip and the wheat harvest have been enormous. The increase in live stock has been proportionate. In 1886 the returns were 9,690,000 sheep and 4,071,000 cattle. The estimate for the present year is 21,600,000 sheep

and 6,250,000 cattle. Such is the difference in countries subject to severe and protracted droughts of a few inches of rain at the right time.—*Pall Mall Gazette.*

COCOA AND ITS COMBINATIONS.—At the Woolwich Police-court, on December 23, Robert Purvis, grocer, was summoned by the Woolwich Local Board of Health for selling cocoa injuriously adulterated with 56 per cent. of foreign matter. The analyst's certificate showed that the sample contained 41 per cent. of cocoa, 40 per cent. of starch, and 16 per cent. of sugar. The inspector by whom the article was purchased said he paid 1s. a pound, and that he brought some for his own consumption, and found it palatable. It was labelled "Rock Cocoa." Mr. Hughes, M.P., who represented the Board, argued that if this was sold as a mixture it ought to have been so labelled. It might be called "cocoa-starch." Mr. Forbes said that cocoa in its natural state contained 53 per cent. of vegetable fat, and this must either be removed or neutralised by the admixture of sugar or some such starch as arrow-root or sago, in order that it might easily be converted into a beverage and rendered fit for consumption. He produced a book written by Dr. Bell, public analyst at Somerset House, in which it was stated that cocoa so prepared would not be considered as adulterated so long as it was not described as pure cocoa. Dr. Bell set down 36'70 per cent. cocoa to be a fair proportion to the other ingredients. This rock cocoa which contained 44 per cent. cocoa, he contended, came under the exception allowed in the Act of Parliament to articles of commerce containing nothing injurious and nothing added for the purpose of fraudulently increasing its bulk. Mr. Kennedy, in giving judgment, said he thought that cocoa came under the exception in the Act, and dismissed the summons.—*Chemist and Druggist.*

NETMUGS GROWING IN THE WEST INDIES.—A good deal of attention is being paid to the propagation of nutmegs in Jamaica. Large quantities of seed-nutmegs have recently been imported there from some of the best Grenada estates. One would-be cultivator has already ordered 10,000 young plants from the Government gardens, and another 5,000. The trees usually yield their first crop when nine years old, and continue to bear for seventy or eighty years. The crop depends largely upon the amount of care bestowed upon the trees, the average in the W. Indies being 10 lb. of nutmegs and 1 lb. of mace every year, but from well-manured trees ten times that quantity has been obtained. A Grenada planter writes as follows to the manager of the Jamaica horticultural gardens :—"The mode adopted here for preparing nutmegs for the London market is very simple. The nutmegs are picked up from under the trees daily and brought into the boucan, where the mace is peeled off and flat between heavy blocks of wood, where it is left for two or three days, then put into a case and left till it reaches the proper colour. The nutmegs are put into receptacles (with fine-wire mesh bottoms so that the air can pass) inside the boucan, and left there for three weeks or a month until the nut begins to shake inside the shell. They are then shown the sun for a couple of hours a day for two or three days. After this they are cracked. Great care is necessary here, for if the outside shell is struck too hard it makes a black spot in the nutmeg which affects the value considerably. When cracked, the nuts are sorted according to size, put into ordinary flour-barrels and shipped. By last mail the average of my prices was about 2s 6½d a lb. In the shipment was included a case of pure rubbish—small shrivelled, worm-eaten nuts fetching about 1s a lb.—*Chemist and Druggist, Jan. 2nd.*

MR. JOHN HUGHES ON "THE AGRICULTURAL VALUE OF SHODDY."

When we first heard that a manure manufactured from old rags was to be applied on the well-known Mariawatte estate, we were under the impression that the use of such a manure as a fertilizer had been at that date comparatively, if not entirely, unknown to English agriculturists. Mr. Hughes had, as we were then told, noticed the effect of the application of old rags to the olive trees of Southern Italy; and we had conceived that it was upon his attention being directed to the beneficial results of such manuring that he had entertained the idea of making essay with a manure of a similar nature to the tea estates of this island. We were subsequently informed, through a conversation had by our London correspondent, with Mr. Hughes, that a fertilizer of the character referred to was manufactured and used at home, but we had no idea that it had received such extended and lengthy application as we now learn from Mr. Hughes' letter to the *Field* it has had. This application appears to have commenced some twenty years back; and it is singular that, if it be possessed of the merit claimed for it by the Consulting Chemist to our Planters' Association, it has not long before this been tried in Ceylon. So far as we have learned, the results to the manure which has been applied on the Mariawatte estate have not yet been sufficiently developed for an opinion to be given as to the value it may possess for our leading local industry. Mr. Hughes has, however, explained that one of the most valuable characteristics of the manure is the slowness with which it yields up its constituents, and he has expressed the belief that in the course of time its relative value as compared with the other fertilisers our tea planters are in the habit of using will become manifest. If his opinion to this effect may be relied upon—and we know no expert in such matters upon whose views we should be inclined to place mere reliance—the letter he has written upon the subject will be of great interest and value. Mr. Hughes applies the term "shoddy"—one of American origin, we believe,—to all kinds of woollen waste generally. This waste may be said to include the cuttings of the tailoring trade, old rags used by mechanics, and a countless number of other varieties produced in different trades. The ingredients of such waste which appear, according to Mr. Hughes' letter, to be possessed of chief value as fertilisers are nitrogen and ammonia. Upon the quantity of these constituents in the manure depends its economic and financial value, and we see that samples which contain 8.85 per cent of ammonia are valued at £3 6s 4d per ton, the quantities and value decreasing through a series of twelve samples until the lowest stage is reached in which there was present but 3.13 per cent of ammonia with a decreased value of £1 3s 5d per ton only. These figures show how imperative it must be, before reliance can be placed upon the manure purchased, that it should be subjected to close analysis and valuation by an expert. Mr. Hughes writes that it is owing to the variableness of the quality of this shoddy manure that its use in Kent, where it has been applied for many years past to the hop vines, has of late considerably fallen off. He refers in his letter under notice to the experiment made on Mariawatte, writing as to this:—"Quite recently, in Ceylon, shoddy (manufactured into a fine powder by treatment with sulphuric acid) has been tried as a manure for the tea plantations; and for these, bearing in mind its richness in organic nitrogen—it promises to prove

an excellent fertilizer, if only it be properly applied and of good quality." We recollect that with reference to the sample applied on Mariawatte Mr. Hughes stated some time back to our London correspondent that unfortunately its shipment had been made without opportunity having been afforded for his making analysis to satisfy himself as to this item of quality upon which he places so much stress. It is possible, therefore, that the at all events deferred success on that estate may have been due to some inferiority in manufacture; and as two swallows do not make a summer we should be disinclined to accept an incomplete result to the sole trial it has received by our planters to denote that it has failed as a valuable fertilizer for tea. We are quite sure that Mr. Hughes would not accept such a conclusion; and from all he has written on the subject it would seem to be certain that this shoddy manure might well receive a further trial on our tea estates, care being taken that the supply to be ordered should be subject to the result of analysis of samples taken after the stuff has been placed on board ship. We should much like to hear from the proprietors of Mariawatte what opinion they have now formed as to the result of the trial given by them to this manure. We have such confidence in Mr. Hughes' judgment, that we feel sure he would not have written so strongly as he has done in its favour unless he felt himself to be fully justified in doing so.

PLANTING IN NETHERLANDS INDIA.

(From the *Straits Times*, Jan. 13th)

In Java, there is hitherto no Labour Ordinance to regulate the relations between planters and coolies though there are enactments of the kind in the outlying possessions. The Home Government thinks that such laws are only required in those parts of Netherlands India, where planters depend on imported labour. As planters in Java do not carry on business with labourers from foreign lands, there is, so it is held, no need to regulate by law the relations between them and their coolies. Java planters find this hard as sometimes labourers recruited from distant parts of the island desert, and the only remedy against the evil is an action at law for the recovery of advances that happen to be made to them at the time of desertion. Of late years, planters in the thinly peopled districts of Java find another hindrance in their way arising out of difficulties in drawing labourers from populous tracts there, as they have to contend against foreign competition in the Java labour market. There are enactments going against the recruitment of Javanese for estate labour beyond the Dutch Indies, but applications for exemption from this prohibition generally meet with a favourable answer from Government. In this way large numbers of Javanese have latterly been recruited for labour in German New Guinea, the Malay Peninsula, the Straits Settlements, Australia, and Dutch Guiana. In 1890, the Government was petitioned by the planting interest in Java to pass a Labour Ordinance there and also to forbid the engagement of coolies in Java for labour abroad, so long as their services are required in the Netherlands Indies, but the Government replied in the negative. The planters have not given it up yet and keep bringing the subject before the public. To strengthen their position, they dwell upon the alleged fact that in British North Borneo there are thousands of Javanese who have never got permission to emigrate, and that these coolies die there in hundreds. On behalf of the planters, it is also alleged that while so much work is made to counteract slavery in Africa, a regular, though an underhand coolie slave market exists at Singapore. The latter assertion has been made on behalf of the Planters' Association at Sukabumie, which evidently seeks to lay particular stress on restricting coolie emigration from Java.

(From the *Straits Times*, Jan. 19th.)

Drought and scarcity prevailed so badly in some parts of Java lately, that, in the province of Japara, the people have been driven to eat their seed paddy, so that when the time came for sowing there were no seedlings. The resident at once supplied the distressed cultivators with paddy in hundreds of piculs. Had they borrowed money for the purpose from usurers, they would have to pay about one thousand per cent in kind for the loan. In other provinces the scarcity of rice and the resulting high prices have compelled the people to have recourse to inferior articles of food. The distress is such that robbery and theft are said to be getting common in that quarter.

The drought has also resulted in great dearth of coffee seedlings on many estates in Java. Large quantities of the available stocks perished owing to the dryness of the season, during which several rivers ceased to run for months. This has proved very hard upon the planters as in consequence of expected high prices, they had cleared large areas for coffee growing. Hence a heavy demand has risen for seedlings, with small supply, and rates have risen from 1½ to 5 guilder cents apiece.

The coffee crop on the west coast of Sumatra, last year, is estimated at about 49,000 piculs.

A Government medical officer has made the discovery that at Cheribon there are six tea factories. This industry seeks to manipulate Java tea to pass for China tea.

THE MILDURA IRRIGATION COLONY.

MILDURA, Jan. 4.—The older orchards, although the trees are still babies, the majority of them being only two years old, have had a most bountiful harvest of early fruits. Apricots have been marvellously prolific, the better kinds being Morpark and Oullians, the early varieties. The local demand is particularly brisk, many growers disposing of the whole crop to the retail fruiterers. Chaffey Brothers' experts are busily engaged drying apricots, the fumigating and sulphuring process being employed. The flavour is pronounced to be delicious by competent judges, and equal to that of the Californian products. The vine harvest will be very extensive, most of the vineyards planted two years ago being of marvellous growth. Some wine will be made, but the greater part of the province will be converted into raisins and sultanas. The more forward of the apricot-trees averaged from 50 lb. to 70 lb. of fruit per tree. Many visitors came during the holidays, and all were deeply impressed with the progress and development of the settlement. Several invested in blocks. An influx of English investors is expected within the next few months. Table grapes are already ripe.

NOTES FROM OUR LONDON LETTER.

LONDON, Jan. 8th.

Last Wednesday saw a goodly gathering assembled at Winchester House to listen to matters having important connexion with Ceylon. The occasion was an extraordinary general meeting of the shareholders of the Ceylon Tea Plantations Company, summoned partly to consider the proposals made by its directors that extra capital should be raised for the purpose of enabling the Company to commence coffee planting in Perak. A former recent letter of mine gave you full details with respect to these proposals.

The meeting was well attended, and the chair was taken by Mr. David Reid. Before the question of undertaking an enterprise in Perak came up, the business of considering resolutions to authorize the directors to purchase certain estates in Ceylon was dealt with. The Chairman stated that the Board desired to obtain tea estates at high altitudes, and the estates it was proposed to buy fulfilled that condition. Although they had paid

£18,000 for the Yoxford estate, which included the highest price they had yet given per acre for tea-planted land, it would, the directors believed, easily return 15 per cent on its purchase money. Begelly was a small estate which its owner had found too small to work profitably, and as it adjoined Tangakelle, they had bought it cheaply for £1,080. As he was personally interested in the Glenlyon and Stair estates, the Chairman said he would ask his fellow-director, Mr. Rutherford, to speak about them, and he would conclude by moving the resolutions. Mr. Rutherford, when seconding these, said that the possession of Glenlyon and Stair would complete the chain of connection between all the Company's Dimbula estates; so that in the event of a factory being burnt down, or a breakdown of machinery, or a pressure of work in any particular factory, relief might at once be given. Mr. Reid was one of the Company's best customers, and if they purchased these estates from him, they would retain the manufacture of the tea from Mr. Reid's other estates. They had had two most competent and independent valuations made of the properties—one of these being by Mr. William Mackenzie, one of the oldest planters in Ceylon. Mr. Reid asked £17,000 in cash and 250 fully paid-up ordinary shares in the Company, and he agreed to plant up with tea all unplanted land at his own expense. Mr. Mackenzie's valuation was £21,290. After these explanations the purchases were unanimously approved by the meeting.

The question of entering upon coffee planting in the Straits Settlements was then taken up by the Chairman. He said the directors believed there was money to be made out of it. They had brought forward no cut-and-dried proposition, but they thought it desirable to recommend the enterprise to their shareholders. The directors had in no way, he assured them, committed themselves to the scheme. The soil and climate of the Straits were well-suited to coffee growing, and this had been proved to an extent that would remove their venture, if made, from being a pioneer one. He admitted there were difficulties in connexion with labour, supervision, and unhealthiness of climate at the time of felling the forest; but all these, he thought, might be successfully overcome, and they had a large labour force in Ceylon and men in touch with the districts on the coast of India from which that supply was drawn. At the worst, supposing the scheme did not answer full expectation, they would but have some £6,000 badly invested, for two years would suffice to make all the useful results apparent. He had himself have interested in coffee planting in Perak for three years, and from his own experience he would recommend his fellow-shareholders to enter upon the venture. The last issue of preference stock made—£40,000—had been placed at 15 per cent premium, so they had £6,000 to start with.

A very full discussion followed, details of which cannot be sent you by this mail. Very divergent opinions were expressed, but the major balance of these inclined to the view that the enterprise was too speculative to be wisely undertaken, and the evident sense of the shareholders was opposed to the directors' proposals. The Chairman then said that, as it was evident his audience was not by any means unanimous as to supporting the scheme, it certainly should not be pressed; but he might confidently contradict the view expressed that it would be of a speculative character. He might say that there was every prospect of their next report fulfilling all the expectations held out by the prospectus circular of last June in

regard to the issues of preference shares, and that too in spite of the very low range of tea prices. Their estates were all doing well, and the young tea was coming on in a way that gave good promise for the future.

Your present staple has been the subject of several important articles in the newspapers this week. The leading one among these appeared in the *Daily Telegraph* of Wednesday last, and of this I enclose you a copy. I can only spare a brief space in this letter to touch upon some of its more important points. The article referred to, which occupies a column and a half, is headed "Indian and China teas: what Mincing Lane thinks—by a City man." It reviews the relative course of trade with regard to Chinese and Indian and Ceylon teas during the last few years, and brings into prominence the supplanting of the first by the two second varieties during the past two years. It says with reference to your own growth that "about 50 per cent more Ceylon tea was used in Great Britain in 1891 than in the year previous," and further states that, while the consumption of Ceylon increased in this large proportion, that of Indian tea was 3 million pounds less in 1891 than in 1890. The article also mentions that "the abnormally wet weather which prevailed in Ceylon during the first quarter of the year occasioned so rapid a growth of the leaf that production fairly outran the most sanguine estimate, and in consequence London became somewhat flooded with unexpected supplies, and a gradual shrinkage in values was the result."

Sir Andrew Clark's late statements then receive notice, and it is pointed out that that distinguished physician made no mention of Ceylon tea. It is further remarked that "speaking generally, Ceylon tea contains far more strength than Indian." As the result of an interview with a representative of the China trade, the rapid displacement of that growth is admitted. Reference is made under this head to Dr. Hale White's report on an analysis of Assam, finest China and common congou teas, but it appears that an infusion of fifteen minutes was allowed before that analysis was commenced. This report of Dr. White's was, I hear, made some years back, and the China tea which yielded so small a proportion as 7.97 per cent. of tannin was, it has further been mentioned to me, a sample which sold for five shillings the pound. This, of course, was quite an exceptional tea, and far beyond the means of the ordinary run of consumers. No fair data could therefore be drawn from its analysis. There is no doubt that the general effect of this article will be good for your Ceylon industry.

A second article was published in the *Gardening World* of January 2nd, and was headed "Something about Tea." It reviewed a recent lecture delivered by Mr. Basil Holmes. This lecture dealt principally with the course of cultivation in Assam, and did not embrace any allusion to the statistical position of the several varieties. The *Chemical Trade Journal* of the same date of issue as the above gave a record by Mr. Joseph F. Geisler of the analysis of a pekoe Ceylon tea. It gives the following result to the analysis of the leaf itself:—

Moisture (loss by drying at 100° C.)	6.20	percent.
Soluble Ash	3.77	"
Insoluble Ash	1.53	"
Total Ash	5.30	"
Theine	5.24	"
Total Tannin	22.79	"
Total extractive matter	43.40	"
Insoluble leaf	50.40	"

The specimen appears to have been of a high-class. A trial was then made of an infusion of it, ten minutes being allowed for this infusion. As the rule, however, few people allow more than five minutes for infusion of Ceylon tea, and we consider that with such a limitation very little of the high proportion of tannin shown by the analysis would be extracted. The second analysis yielded the following results:—

Theine	2.44	per cent.
Tannin	17.19	"
Total extractive matter	33.25	"
Ash (total)	3.44	"
Phosphoric Acid (P ₂ O ₅) in ash	6.18	"

The infusion is stated to have been of a golden yellow colour and as having "a very agreeable aroma and pleasant taste." It is stated that this ten minutes of infusion took up 96.6 per cent of the total theine, 75.3 per cent of the total tannin, and 91 per cent of the soluble ash. The article was extracted from the *Journal of the American Chemical Society*.

With reference to the three articles above referred to, it may be useful to tell you what passed in a conversation lately had by myself with a man largely engaged in the China trade. In effect he remarked:—Admitting all you say as to the degree in which Ceylon and Indian teas are supplanting those of China, I can only say that we do not fear the continuation of the present competition by Ceylon teas. Your soil is not suited to permanent production of this, any more than it proved to be for coffee. Some years back certain Ceylon estates were noted for some specially high class teas. One never hears of such teas now on the market; nor of the high prices which were formerly obtained for such. This proves a gradual decadence in quality which in time will show itself universally." On my mentioning these remarks to a gentleman of planting experience in Ceylon, he observed:—"In one sense only was your friends right. We do not hear of any teas of exceptional quality from certain Ceylon estates as we used to do. But why is this the case? Firstly, because the quality of the whole export from Ceylon has, as the rule, been levelling up; and secondly, because the production of small breaks of exceptional quality did not prove to be a paying investment. If your friend had been acquainted with these two facts, he would not have inferred a deterioration due to unstable conditions of soil."

We hear that your Mr. John Ferguson has been actively endeavouring to stir up Sir William Gregory and Sir Arthur Birch to take steps to publicly refute the statements recently made by Sir Andrew Clark with reference to the superiority of China over other varieties of tea. We have not heard if he has been able to induce either of those ex-officials to take up the cudgils, but the general view is, we think, that as Sir Andrew did not specifically name Ceylon tea, it would scarcely be a sufficient object for either of the gentlemen mentioned to undertake the work necessary for the purpose of publicly refuting his uncalled-for assertions.

◆◆◆◆◆
 CEYLON TEA IN EGYPT.—The *Egyptian Gazette* of 15th Jan. says:—

Messrs. Edgar Kirby & Co. have requested us to insert in our columns, for the information of their numerous clients, that they have just received from Ceylon a fresh supply of Pekoe Soncheng as well as a trial shipment of "Orange Pekoe." Both these teas mixed together in equal proportions, will give a strong rich and delicious flavour.

JAVA TEA BEING PREPARED AND PASSED OFF AS CHINA IN BATAVIA.

Visitors to Java even more than in the case of Penang and Singapore must be struck by the preponderance of the Chinese element in the population of Batavia. To meet the tastes of this population, "an ingenious device" has been adopted by some Java Chinamen, for a brief description of which we are indebted to a correspondent, who writes:—

In the last number of the "Teysmanita" which you were kind enough to send me there appears an interesting article headed "Thee-veralsering op groote schaal te Cheribon" (Tea adulteration on a large scale at Cheribon). It is not what would be generally called "adulteration" in the ordinary sense of the term, but the preparation of inferior kinds of Java tea, by scenting it with flowers and putting it up in packages with labels in the Chinese characters setting forth that it is made in China. It is sold to the large Chinese population in Java and to the Javanese as China tea, of superior quality. As there is an import duty of 10c. (of a guilder) on China tea, this acts as a protecting duty to those engaged in the trade. The writer of the article gives a full account of the mode of preparation. If you think that a translation of the article would be suitable to the *T. A.* or any of your publications, I shall be glad to translate it, and to send you the translation. As this business must cause a certain loss of revenue it is probable that the public prosecutor will come down on the industrious, ingenious and unscrupulous Chinaman.

We shall be glad to have the translation.

THE CEYLON TEA PLANTATIONS COMPANY AND PERAK.

We could not say with truth that we regret the decision come to at the meeting of the above-named Company to abandon the idea of undertaking coffee planting in Perak. It is not that we should not wish well to any enterprise of the kind if it were undertaken by a Company that was wholly independent of planting or other pursuits in Ceylon; for it is unfortunately now the case that we have no such prospect before us of the resuscitation of coffee planting in this island that we need feel any jealousy of efforts being made to grow our former staple in any other country. But we have in former times given our reasons for deprecating the association of the name of Ceylon with enterprises conducted without its boundaries. Most of our readers will recollect that when the affairs of the Ceylon Company first became involved that Company was for years buoyed up by the large profits it was making out of its investments in this colony. All the time these profits were being made here, things were going from bad to worse in Mauritius, where the Company had had to take over a number of sugar estates on which the then Oriental Bank had made large and dangerous advances. Year after year these estates were worked at a dead loss, but the actual position of the Company's affairs was concealed by the announcement it was still able to make of substantial dividends, the entire, and more than the entire, of which had been earned in connexion with Ceylon. When the final crash came consequent upon the ill-advised stoppage of the Oriental Bank—a stoppage which we all now know to have been unnecessary and timorous—it was natural for the home public, unacquainted as it was with the full and peculiar circumstances of the case, to lay the whole onus of the failure at the door of unfortunate Ceylon. It is needless to say how seriously this misconception affected the credit of this colony at a time when the maintenance of that credit

was of the most particular importance to us; and had the directors of the Ceylon Plantations Company obtained the warrant of their shareholders to graft upon their parent stem an enterprise in a comparatively untried region for coffee planting such as is Perak, we should have been in constant dread lest a recurrence of similarly damaged credit might have to be faced. It is for this reason that, as we have said, we can feel no regret that the shareholders of the Ceylon Plantations Company have vetoed the proposal submitted to them by their Board of Direction. We suspect that most of these shareholders either have, or have had, some connection with Ceylon, and in that case we have little doubt that they retain in their minds a painful recollection of the result to what we may term a foreign association with the name of this island which we have above quoted, and it is certain that their decision to refuse compliance with their directors' recommendation would have been largely influenced by such a recollection. Nor, when we come to consider other points in the matter submitted to the meeting, can we feel surprised at the disfavour with which it was viewed. The generally expressed opinion seems to have been that the suggested enterprise was of a speculative character. It was all very well for the Chairman to deny this; but all unprejudiced men will, we think, agree that the commencement of a new, or nearly new, industry in a comparatively untried country must necessarily partake of a speculative character. Into such an undertaking it was only natural that a body of shareholders secured by present investment in a known and well-tried industry should object, for this alone, if for no other reason, to see the character of their existing undertaking altogether changed. The Directors, when sending out the circular in which their proposals as to Perak were first mooted, mentioned as one of the chief inducements that they could hold out that, being already the employers of some six thousand coolies in Ceylon, they would be in a position superior to the difficulties at present attendant on the labour supply of Perak. But it must be assumed that, if the Company possesses this amount of labour, the whole of it is needed for the cultivation of its Ceylon estates. In that case it could not afford to transfer any portion of it to Perak, nor could the coolies be sent to that country without fresh and special agreements being entered into with them, and it would be at least questionable if any large proportion of them would care to have their services transferred to a new and, to them, an unknown country. But quite apart from all reasons which may have actuated the shareholders towards their refusal of their Directors' propositions, there stands out prominently the one fact that, by that refusal, this Colony is saved from the chances of once again being made the stalking horse for a speculative and possibly losing investment.

EFFECT OF THE COLLAPSE OF THE FOCHOW TEA TRADE.—The Fochow Echo of 2nd Jan. says:—

Accounts reach us from Kiengning-foo of most daring robberies. Bands of thirty or forty ruffians enter the houses of wealthy people, blindfold and gag the unhappy inmates, and then help themselves, and make off with all that is best worth having of the valuable contents. This is described to us as one of the results of the decline of the tea trade. Many hundreds of men (our informant said thousands), hitherto earning an honest living from it, are now driven from sheer hunger to become burglars and highway robbers.

GEOLOGISTS have proved that the diamond mines of South Africa are situated in vents or chimneys, varying from about 70 feet to 1,500 ft. in diameter, and descending vertically through the schists which form the ordinary strata of the district. These vents are filled up with fragments of silicated and magnesian rocks, in which the diamonds are scattered, and before the diggings began each was capped by a hillock, or "kopje." They are 17 in number, and run in a straight line about 120 miles.—*Fiji Times*.

THE TEA CROP OF 1892: MR. H. K. RUTHERFORD'S ESTIMATE.—Of all the estimates of the current year's tea crop from Ceylon that have yet appeared, ours (80,000,000 lb.) is the lowest. But Mr. Rutherford makes his estimate lower still. Writing to us by this mail he says:—"With regard to the estimate of crop for the year 1892, I will not venture to predict more than 74 millions. Last year upset everyone's calculation, and it therefore makes it more difficult to estimate what the present year will do." This opinion thoroughly coincides with that which have repeatedly expressed, namely, that last year's figures form no reliable guide. The total output was abnormally large, and, as there is no reason to suppose that the current season will be so peculiarly favorable to the abundant growth of leaf, the actual increase show over the figures for last season is not likely to be large. We think 80 millions is an outside estimate.—*Local "Times"*.

COCONUT PLANTING.—During some years past, owing to the excessive and prolonged droughts killing large numbers of trees in several estates, the prospects of coconut planting in the peninsula were very gloomy indeed; and the prophets of evil to whom the proposed railway to Jaffna was at first a wild and visionary project unworthy of their support, boldly foretold and stoutly maintained that, in view of the severe crisis through which the estates were then passing, it would be idle to rely on them for any appreciable item in the calculations made of the probable traffic available for the proposed line. The planters however have now good reason to take heart, thanks to the abnormally copious and constant rains we have had during the last three months; and I have it on the best authority some of the planters themselves, that the year 1892 has dawned on them with excellent prospects. The out-turn of copra during the first half of the present year will doubtless be exceptionally large and such as to make up, in great part, for any loss they have sustained during the trying period of recurring droughts to which I have briefly referred.—*Cor., Jaffna "Patriot"*.

OUTPUT OF TEA THIS SEASON.—A planter of many years' experience in Ambagamuwa writes to say:—"I think your estimate of our total export of tea this year high—though it is the lowest of any yet given. I very much doubt if the crop of 1892 will much exceed that of 1891, which was much increased by the extraordinary rush of leaf during the first six months of the year. It was further aggravated by shortness of labour, which compelled many to pluck very heavily, for it was a case of letting it go or making it into tea. This resulted in large quantities of inferior tea being placed upon the market. This year we are better off for coolies, and, after the weather we have had, it is doubtful if we shall have the same rush of flush again, nearly every estate going in for finer plucking, which will result in a decrease in quantity of from one-third to nearly half. This, I fancy, will nearly balance the increase for the year and keep the output about the same. I know one place—a sample of many others— which gave over 400 lb. per acre last year and only plucked medium, but which, with finer plucking, only expects this year to make 270 lb per acre."—*Local "Times"*.

THE INDIAN RICE CROP.—The Government of India, Revenue and Agricultural Department, have issued the following second general memorandum on the rice crop in Bengal, Lower Burma, and Madras for the season 1891-92:—"The following statement gives the corrected figures of area under the crop in the three

chief rice-growing provinces, compares them with the normal and past year's acreage, and indicates the estimated outturn in annas:—

Province.	Acreage.			Estimated out-turn in annas.
	Average.	1890-91.	1891-92.	
Bengal	34,577,000	32,816,000	31,254,000	9½
Madras	4,559,000	4,582,000	4,414,000	10
Burma	3,519,000	3,916,000	4,107,000	12 to 18
Total	42,655,000	41,344,000	39,775,000	...

In Bengal the unfavourable character of the rainfall in the months of July, August, September, and October occasioned a considerable deficiency both in the area and in the outturn of the winter crop, to about 6 annas of an average crop. In the deltas and on the west coast of Madras the crops are fair, but elsewhere they are estimated at only half the average. In Burma, notwithstanding a decrease of area since the report published on 22nd October last, the condition of the crop is satisfactory, and it is estimated that there will be available for export about 1,030,534 tons of cleaned rice including the amounts required for Upper Burma.

COFFEE AS A BAROMETER.—A Portuguese has made a startling discovery that every time a man drinks a cup of coffee with the usual seasoning of sugar he drinks—a barometer. "Ah!" you sigh, in self commiseration, "no wonder the coffee I drank last night kept me awake until four this morning." But wait; it is not a joke. Hear what Dr. Souvegron says on the subject. If sugar be cast into the coffee without stirring or agitating the cup, the bubbles of air contained in the sugar rise to the top of the liquid, and it is this that converts a cup of coffee into a barometer. If the bubbles form a foaming mass, keeping well to the centre of the cup, we have the indication of fair weather; if, on the contrary, the foam directs itself to the edge of the cup and remains turning like a ring, it is a sign of rain; if stationary, not large in the centre, it indicates variable weather; if it all moves, without separating, to one point near the edge of the cup, another indication of rain. Dr. Souvegron affirms that all these indications were confirmed with a holosteric barometer and another of mercury. "We have not yet made the experiment," says our Portuguese reporter, "but hope to, the Fates consenting." He adds that in order for the phenomena to be reliable the coffee must be pure.—*Pharmaceutical Era*.

OUR TEA TELEGRAM.—We think our telegram from Messrs. Wilson, Smithett & Co. this week is more hopeful, or at all events less despondent, than was the last one. The market is quiet, but prices remain steady. The average is low, and the trade are evidently waiting to learn the total exports for the month of January, which they will do today from several sources. The information thus supplied to them is likely to cause some surprise, we expect, seeing that the figures are some 4,900,000 lb., a quantity actually less than that shipped during January, 1891. We believe this is the first time in the history of the tea enterprise of Ceylon that the shipments of one month have totalled less than the corresponding month of the previous year. It only bears out, however, what we have frequently insisted on, that the output last year was quite exceptional, and that in all human possibility the export of this season will exhibit but a small increase upon it. Tea is coming down from upcountry comparatively slowly, and we do not anticipate a heavy shipment in February. It will probably amount to 6,000,000 lb., at the outside. This a very different result to what was anticipated. The fact is that the long-continued rain in December stopped flushes and reduced the current month's shipments; but, now we are getting warm weather, we anticipate that shipments during February will increase to something under 6,000,000 lb. When these facts become known in the Lane, they may bring about a better tone in the market, for there does not seem to be any real warrant for the present low prices.—*Local "Times"*.

MALODOROUS SUBSTANCES AND TEA:
TOBACCO TABOOED.

As it is the last straw which breaks the camel's back, so the refusal of the shipping agents to arrange freight for the tobacco they had grown and prepared seems to have been the final misfortune which led to the collapse and liquidation of the Ceylon Tobacco Company. The shareholders, most of whom are tea producers and exporters, must have cordially approved the good judgment of the shipping agents. It is nevertheless a ludicrous position for the tobacco to occupy that it can neither be exported nor sold locally. The leaf must be of a superior quality to that grown at Jaffna, and there is the objectionable distinction made by the native government in favour of Coimbatore tobacco, or we should feel inclined to say "Try Travancore." We suppose the objection to carry the tobacco in steamers which load tea is, that the former substance is in bulk. To small quantities of cigars well secured in boxes we fancy no more objection would be offered now than in the past. But stalks of leaf tobacco, in large quantity even if enveloped in gunny cloth would give out an odour pervading every portion of the ship in which they were carried,—an odour which, if absorbed by so sensitive a substance as tea, would be ruinous in its effects on the absorbent substance. It may be taken for granted that neither now nor in the future will the same vessels carry tea and tobacco; and as the production of the narcotic leaf has not reached such proportions in Ceylon as to render any quantity that can be offered for cargo an inducement to a vessel to carry tobacco to the exclusion of tea, this freight question alone seems to constitute such a "heavy blow and great discouragement" to the tobacco enterprise in our island—we are of course referring to the finer leaf grown by Europeans,—that we may look on its knell as having been sounded? We are of course sorry for those who invested money in what promised to be a profitable enterprise, and which has belied all the expectations formed regarding it by men whose sagacity is not generally at fault. The lands seem to have been far too widely separated to render good management easy and as a matter of fact the management, whether from want of attention or paucity of money and labour, seems to have deserved denunciation as disgraceful. The difficulty of obtaining freight for tobacco, even if it had been grown in quantity and of the right quality seems not to have been foreseen. We suppose we may now take it for granted that tobacco of the finer descriptions and as the object of enterprise by Europeans is not likely to rank amongst the leading exports from Ceylon. For that condemnation we cannot personally express regret. Soil suitable for tobacco, which must be rich in all the elements of fertility, especially potash, can be much more legitimately devoted to the growth of our really staple products, valuable for human food and economical purposes:—tea, cacao, coconuts, cardamoms, &c. Happily those of our leading exports which possess a marked odour are pleasantly odorous, and we do not suppose that any objections ever have been or ever will be offered to the carriage of cinnamon and cardamoms in the same ships with tea, such as have "tabooed" tobacco. Pepper does not enter into our exports, while coconut oil and the essential grass oils are so well secured as not to give forth their special odours. Coconut oil and tea are, however, not stowed in the same holds, we believe. The odour of cinchona bark and coffee would scarcely affect tea injuriously even if they reached it in any save a very

diffused form. The only pleasant feature in the report of the unfortunate Ceylon Tobacco Company, Limited, is that which indicates the jealous care of shipping agents to prevent the presence in vessels which carry our now great and leading staple product—sensitive in proportion to its delicacy—of any substance, the odour of which might injure that flavour, on the purity of which the value of tea so essentially depends. For the emphatic assurance of this fact we are indebted to a report which is otherwise not pleasant reading.

FROM THE METROPOLIS.

THE CEYLON TEA PLANTATIONS CO., LD.

Jan. 8th.

You will doubtless hear from your regular correspondent about the meeting of the Ceylon Tea Plantations Company as reported in the *Times* and other journals. The purchase of Glsnyon and Stair estates as well as Begelly and Waverley is interesting to Ceylon readers, as also the continued prosperity of the Company, which is, I suppose, the most important and most truly representative of Ceylon and its great enterprise amongst all the Tea or Planting Associations connected with the island. For this very reason, apart from other reasons, I for one am pleased, rather than disappointed, that Sir William Gregory has been able to prevent this Company extending its operations to coffee even in the Malayan Peninsula. I cannot see any cause to doubt the good accounts given of the prospects before coffee plantations in Perak; and Sir Grace Elphinstons, Mr. Reid, and others will, I trust, profit largely by their operations and investments there. But if there is work suitable for a Company there, let it be a new and distinct one—The Coffee-growing Company of Perak or Malayan Peninsula—rather than an extension of the institution so generally identified with Ceylon and tea. There is the example of the Ceylon Company, Limited, before us and the many years that the good name of "Ceylon" suffered through the incubus of Mauritius sugar-planting business on this old "O. B. C." Company. It may, and I trust will, be quite different on the case of coffee and the Straits; but far better that Ceylon should have all the honour, or the blame, attending the success or failure of its premier Tea Company, than that there should be a mixing up of investments belonging to two different colonies under the name of our island. Mr. Reid and his co-directors have therefore acted wisely, I think, in listening to Sir Wm. Gregory's objection and in giving up the idea of extending the Company's business to coffee in Perak. There need be no fear that a separate Company to deal with the latter will be liberally supported if promoted by Messrs. Reid, Rutherford, and the many who have the fullest confidence in their shrewdness, experience and sound judgment as men of business well acquainted with tropical plantations. I append the report of the Company's meeting which has appeared in the *Daily Chronicle*, feeling sure that the one from the *Times* (rather different in some parts) will reach you from your regular correspondent:—

PUBLIC COMPANIES.

CEYLON TEA PLANTATIONS.

An extraordinary general meeting of the Ceylon Tea Plantations Company, Limited, was held yesterday, at Winchester House, Old Broad-street, Mr. D. Reid presiding.—The Chairman said that the shareholders had been called together in order that their approval of certain acts of the directors might be asked. In

regard to the extension and expansion of the company's tea estates the general scope of the directors' policy had been directed to increasing the area of cultivation in high altitudes, and to acquiring estates of exceptionally high quality. They thought they had so far been successful in carrying out that policy, and the purchases which they now asked the shareholders to sanction fulfilled those conditions. The highest price they had yet paid for an acre of tea-planted land was for the Yoxford, which was undoubtedly a very fine property, and well worth the £18,000 paid for it. It would easily give 15 per cent. on this outlay. Begelly was a small tea estate adjoining Tangakelly, which the owner found too small to work as a separate estate. It had been bought cheaply for £1,081, and would be a valuable addition to Tangakelly. He moved—"That the directors be authorised to purchase or acquire from the owners thereof the following estates in Ceylon:—Yoxford, containing 478 acres; Glenlyon and Stair, 638 acres; and Begelly, 48 acres, at prices not exceeding in the whole £38,551."—Mr. Rutherford seconded the resolution, which was carried.—The Chairman said he had now to invite their consideration and advice in a matter that the directors were in no way committed to, but which they thought well of. Mr. E. A. Talbot, their manager in Ceylon, who paid a visit to the Malay Peninsula in October last had come to the conclusion that the cultivation of coffee yielded results which would warrant them in extending their operations into that country. The reason the directors proposed this was that they thought there was money in it. There were difficulties to be encountered, and these were labour, supervision and unhealthiness of climate at the time of felling the forest, and the opening up; but if these difficulties were successfully met and overcome he had no doubt that coffee planting in the Straits would be a financial success. With regard to the risk, he believed they would know in two years, with nearly absolute certainty, how it was going to answer, and the very worst that could happen would be to have £6,000 badly invested. If it succeeded they would be in a splendid position to select the best land obtainable, and to develop a most remunerative industry. The whole of the last issue of preference stock, £40,000, had been placed at a premium of 15 per cent., so they had £6,000 to start with, and they anticipated that this fund would supply all the cash required for their purpose.—Sir William Gregory said he regarded this proposal as a speculation alien to the original intentions of the company. The company was doing remarkably well, and it was but common sense to let well alone. Coffee had proved itself to be a dangerous article, and he thought they would be very ill-advised to touch it.—The Chairman pointed out that the memorandum of association gave them power to cultivate any product. But that was not the question. It was whether it would be a judicious thing to do, and he need not tell the shareholders that it would not be forced on them by weight of votes, but would be dropped if there was any considerable opposition to the scheme. They had not lost their confidence in Ceylon; but this matter had been recommended very strongly to them by Mr. Talbot who had had a long experience in coffee.—After some discussion the Chairman announced that the directors had decided not to go further in the matter. They regretted it, but they wished to consult the wishes of even the smallest shareholders. He might mention before they adjourned that they had now a very fair idea of the report which the directors would be able to make to them in April, and they believed it would realise all that was put forward by the directors in their circular of June last, notwithstanding the very low range of tea prices. The estates were all doing well, and the young tea was coming on in a way that gave good promise for the future.—The meeting ended with a vote of thanks to the Chairman.

Sir Wm. Gregory spoke to me about the meeting, the day before, and I occurred in the soundness of the view he adopted, even though believing that there is a prosperous planting future before Perak and other Straits Settlements,

CEYLON TEA—SIR ARTHUR BIRCH—SIR ANDREW CLARK
—MR. ELWOOD MAY, & Co.

Dec. 31st.

Calling at the Royal Geographical Society the other day to see my friend Mr. Scott-Keltie, the accomplished Secretary,—of whose work, more anon,—I found myself, on leaving, opposite the Western Branch of the Bank of England and remembering that an ex Ceylon official is at its head, I ventured on a call. Sir Arthur Birch, our former Lieut.-Governor (and who certainly by this time would have been a first-class Governor had he remained in the service) received me very kindly and quickly showed that through his reading of the *Overland Observer* as well as many other channels, private as well as official, he keeps up a full interest in Ceylon affairs. He mentioned in fact that old Ceylon friends frequently drop in to see him, and he has a personal interest in plantation property through the New Dimbula Company; and indeed the extraordinarily rapid increase in production of tea on Diagama gave the text to a conversation full of interest bearing on the future of Ceylon. Sir Arthur thinks over-production of our staple and the consequent lowering of prices to an unprofitable scale, is the one great danger before us; and, of course, with the statistics of crop and export shown for five years past, no one can gainsay this view. Unless Australasia and America come to the rescue by taking off larger quantities of Ceylon and Indian teas, consumption in the United Kingdom (and Continent of Europe), good and growing as it is, can scarcely meet the ease. There is, of course, the good hope that the China tea trade has got a heavy blow and sore discouragement this season; but it may recover. In reference to America Sir Arthur spoke in high terms of the enterprise and (so far as he could judge) the business character of Mr. Elwood May, who he certainly thought was entitled to be regarded as a benefactor to the Ceylon tea enterprise, were it only for the persistent way in which he had advertised our staple in a country where advertising was the only certain way to establish a trade. He entirely agreed with the view that the planters ought to be much pleased (in place of dissatisfied as a few at least of them seem to be) that Mr. May came forward to support and extend the Ceylon-American Company at a time when, under the old conditions, it was bound to collapse. The benefit to Ceylon of all that has taken place since is in the advertising—the making sections of the American people acquainted with our teas,—and this work is bound ere long to bear fruit; for to judge by the files of American papers, circulars, pamphlets sent across by Mr. Elwood May, he is still indefatigable in his work of advertising our staple.

I drew Sir Arthur Birch's attention to the mischief Sir Andrew Clark had done by his ill-advised and utterly incorrect utterances on Ceylon and Indian vs. China teas before medical students in his latest hospital address. It was no doubt corrected in different ways at the time; but Sir Andrew's reputation is high and his words continue to be most prominently placarded in the windows of China tea dealers, notably in Regent Street and other West End quarters, and one can read their import sticks in the memory. In fact I have had personal experience of the fact only too often in going about. Sir Arthur Birch fully agreed—he had, in fact, intended speaking to Sir Andrew Clark, who is a personal friend, on the subject. I pressed him to do so, and that if some Dimbula tea could be given Sir Andrew to try under the proper conditions of a smaller quantity to infuse at a time, than of China, he could not fail to change his opinion. It would indeed be

worth while trying to get Sir Wm. Gregory—another old friend of the fishable physician—and Sir Arthur Gordon, to try and bring him to reason, and a confession of error which could be as prominently advertised and placarded. This is required in order to counteract the effect of the speech, to the mischief of which several Ceylon planters at home (among others) have drawn my attention.

But as I wrote before, it is very necessary that the Ceylon planters themselves should do their part to keep up the reputation of their staple by finer plucking and more careful preparation. One proprietor writing to me from Aberdeen some weeks ago said:—

“Alas! for Ceylon tea. It seems to have fallen on an evil time. And to make matters worse I see some one writing again in the *Overland* how cheaply it can be made. These people are in reality a curse, as people often associate ‘cheap’ with ‘worthless.’ Several leading tea dealers here have remarked on this to me and I see an advertisement ‘pure Ceylon tea 1s 6d, and pure Indian 2s 6d.’ Already the grocer has made the discovery that Ceylon tea is cheap and that the consumer knows it. In my opinion the publication of these figures do a great deal of harm and no good. And for the most part they do not represent things properly, as sometimes the cost of manufacture (as given) would not pay a decent tea-house conductor. No doubt they will find out their mistake soon enough, but others too will have to pay for their imprudence. I saw a fair Ceylon tea lately with a genuine estate mark, that cost 4d per lb. Any good we got from the sales of fancy teas is neutralised by the idea that the balance costs almost nothing.”

I quote this in order to add that the same gentleman writing on the 28th inst has a better account to give, among other news, as follows:—

“Prices of Ceylon tea seem to be improving slightly. Let us hope they may improve still further.— writes me from Ceylon that the planters are waking up to the danger of coarse plucking, and the necessity of finer plucking systematically. I see by last *Observer Overland* the praiseworthy approach by Sir Arthur E. Havelock to the Governor of Madras, and the ready way in which he has been met in regard to encouraging the famine-stricken coolies of the Presidency to go across and gather their share of the good things to be had for their labour on Ceylon estates. I have been reading not only your letters from Carlsbad, but the *Chemist and Druggist* had an article I took to be yours, taken, I suppose, from the *Observer* or *T. A.*, viz. an account of a visit to a quinine manufactory.”

As bearing on our “tea” question, and cheapness of production, here is a paragraph from a City article in the *London Star*, which, perhaps, you may not have seen:—

THE IMPORTS OF TEA.—The shrinkage in the exports of Chinese teas—at any rate, in the exports to this country—continue. Twenty years ago Englishmen drank little but Chinese tea; China was practically our only source of supply. But since then India and Ceylon have been forging ahead, and the transfer of custom shows no signs of stopping. Whilst the imports from India and Ceylon show large increases, those from China to date show a falling off of 6,000,000 lb. The average price obtained at the public sales in November of Indian tea was 8½d per lb., a fall of ½d as compared with October. It used to be said by the tea planters that they could not cultivate at a profit under 1s per lb., but, like the sugar planters, they have found it possible to pay their way at a much lower minimum than that they need to think the lowest possible.

MR. J. L. SHAND—PACKAGES FOR THE SWISS PACKET TRADE OF PURE CEYLON TEA—CEYLON COCOA AND CEYLON CHOCOLATE—CEYLON TEA EXPORTS—SIR ANDREW CLARK'S STATEMENTS—INDIAN AND CEYLON TEAS—BRITISH INTERESTS IN CHINA—STAVELESS CASKS—LIP-TON AND HIS TEA TRADE—GENERAL NEWS.

Jan. 8th.

Mr. J. L. Shand, who leaves tonight to catch

the French steamer at Marssilles, naturally looks to North Borneo as fulfilling the requirements of tropical planters in search for new and suitable forest-land. He thinks the labour difficulty will prevent much being done in Peru, but of this we shall be better able to judge when the report from Messrs. Ross and Sinclair appears.

I have been much struck with the neatness of the packages prepared by Messrs. Shand & Haldane for their Swiss packet trade of pure Ceylon tea. They are most tastefully and conveniently made up with explanations in English, German and French, and ought to be very suitable for sale and use all over the Continent. I have suggested the addition of instructions as to the proper infusion of tea, after the very full, careful model adopted in Austria, and then all interested in spreading the use of pure Ceylon tea on the Continent of Europe may feel certain that they cannot have a better agency than the “Ceylon Planters' Direct Supply Association of 21, Rood Lane, E. O.” I have also, as one quite impartial and disinterested been much struck by the good work done by this firm in promoting the consumption of pure “Ceylon cocoa” in a manner at once convenient, economical and delightfully pleasant. I do not think this branch of their business is sufficiently known and appreciated in Ceylon. Messrs. Shand & Haldane have works at Norwich, where their “ESSENCE OF CEYLON COCOA” and “CEYLON CHOCOLATE, VANILLA FLAVOURED,” are prepared. The former is made up in handy tins, and is labelled, “Pure, free from all admixture of sugar or farina, and specially adapted to invalids and others of weak digestion.” No doubt a good many in Ceylon know and use this “cocoa” and the green-packeted, delicious chocolate. But I am anxious to explain that this “cocoa” has all the advantages of the preparation from “nibs” by long boiling to get rid of the fat, because in its preparation the fatty substance is nearly all removed. A cup of the essence can, therefore, be prepared as quickly as a cup of tea, and as suitable as the latter for anyone's drink in the tropics. I learned that 50 per cent of the weight of the said product as grown in Ceylon comes off in fat, and Mr. Shand showed me cakes of this substance beautifully clear and free from rancidity however long kept, so that there is a demand for it (cocoa-fat) for surgical, among other purposes. I am sure all interested in the cultivation of Ceylon “cacao” should do all in their power to make known among their friends and acquaintances the Rood Lane firm's “Essence of Cocoa” and “Chocolate” as two of the very best and purest preparations therefrom.

To return to CEYLON TEA. A good deal of reference has been made to our staple this week in connection with Messrs. Gow, Wilson & Stanton's annual statement of imports and deliveries for all tea; and speculation is rife now as to the probable total export from Ceylon during 1892. I have been questioned several times in the City on this point. At the end of 1889 I put the total export of 1891 at about 61 million lb., but raised this to from 68 to 70 million lb. under the influence of the enormously developed shipments in the first and second quarters of 1891. The falling-off in the last quarter, however, teaches caution, and I am inclined to agree with the feeling prevalent among Ceylon men in the City that it will not be safe to put the total exports of Ceylon tea for 1892 above 75 to 78 millions lb. It is true this would only give an increase of 10 to 13 million lb. against the advance of over 18 millions between 1890 and 1891. But lower prices are not encouraging in regard to areas on old coffee land yielding less than 300 lb. an acre, and the bulk of

our acreage must have reached its full bearing capacity. Nevertheless, according to the Directory figures, no less than 22,000 acres of additional land were planted with tea between 1888-89, and this should undoubtedly add to the crop of the present year. The most important reference to tea in the London dailies of late has been the following from the *Daily Telegraph* of 6th Jan:—

INDIAN AND CHINA TEAS.
WHAT MINCING-LANE THINKS.

[BY A CITY MAN.]

Everybody who has any knowledge of the facts admits that the present position of the tea trade is peculiarly interesting, not merely to capitalists, speculators, planters, brokers, and merchants, but to the public at large. The consumer, however, appears to be still ignorant of points which are freely discussed in Mincing-lane, in the public sale rooms of which the auctions have recommenced. In order to place the views of the different sections of the trade upon an authoritative basis, I have consulted experts in each of the three branches, for in that way only has it been possible to ascertain the relative prospects of India, China, and Ceylon. One of the firms to whom I applied for information was Messrs. Gow, Wilson, and Stanton, whose tabular statements, issued from time to time, are regarded as perfectly trustworthy, based as their statistics are upon official returns. In answer to questions, members of the firm named said: "Our own possessions now contribute about 75 per cent of the tea we consume, and only 25 per cent is supplied by China. The home consumption in 1891 exceeded any previous record, and amounted to 202,000,000 lb. Look at this table."

The table showed that less China tea was used in 1887 than in 1866, when, practically, China supplied the whole market; but, on the other hand, in 1887, an almost equal weight of Indian and Ceylon tea was drunk in addition to the China tea. Since 1887 the importations from China have continued to decline and those from India and Ceylon to increase. I may add to this information from figures derived from the Board of Trade returns. It appears that in 1891 the consumption of Indian and Ceylon amounted to 150,000,000 lb, and that of China, &c., to 52,000,000 lb, or, according to the accepted standard, the equivalent of 39,000,000 barrels in fluid tea, and it is interesting to note that it is computed that the consumption of liquid tea jumped up 2,500,000 barrels in 1891, and that of 1890, in its turn, had been 2,000,000 above the total of the preceding year.

"Amongst the features of the past year, I understand, have been the continued decline of the arrivals of China tea, the standstill in the consumption of Indian, and the remarkable growth of the importations from Ceylon?" I suggested.

"So long as the weaker teas of China were being rapidly displaced by the stronger teas of India and Ceylon," was the answer, "the increase in the consumption of dry leaf was hardly appreciable, although a larger quantity of liquid tea was being used. The displacement of China teas during the last two years has not been very marked; hence the greater weight of tea required to supply the gradually expanding liquid consumption. This fact, with the reduction of duty last year to 4d, is doubtless answerable for the heavy increase in the use of dry tea. There is this remarkable feature in the home consumption of the past year. For the first time, Ceylon tea has been more largely drunk than China tea. In 1887 10 000,000 lb only of the former were used, to 90,000,000 lb of China tea. In 1891 the use of Ceylon tea increased to about 50,000,000 lb while the quantity of China tea was reduced by about 40,000,000 lb, Indian tea supplying the bulk, i.e., about half, of the home consumption. About 50 per cent more Ceylon tea was used in Great Britain in 1891 than in the year previous. Extraordinary low prices were current during the last few months for the lower grades of Indian and Ceylon tea, those constituting the main

portion of the tea drunk in this country. They were obtainable at a lower price than was ever previously known."

"Well, what of the future?"

"During the early part of December the very low prices then current for Indian and Ceylon tea caused increased competition, and resulted in a rise amongst the lower grades, which supply the bulk of the consumption, of about a halfpenny to one penny per pound. This rise has since been maintained, and at the first sale of the year, which took place for Indian teas on the 4th, and for Ceylon teas on the 5th inst., the prices at which the year closed have not dropped. But it is idle to say whether we are likely to have tea dearer. People's ideas differ, Ceylon tea may go dearer because it appears to be most in demand. Its consumption increased 50 per cent. last year, whereas, although Indian tea fell in price, the consumption has been 3,000,000 less than in 1890. There are many things which we cannot calculate upon in forecasting the markets."

"What was the cause of the late depression?"

"In Indian teas the year opened with very high prices for low grade teas, short supplies being anticipated both from India and China, but prices gradually fell off until the close of the year. Fine flavoured teas and teas of exceptional quality have been scarce, and commanded full rates. The general quality of the crop has not been equal to that of last year. With respect to Ceylon, the early months of 1891 were marked by high prices for the low grades. The abnormally wet weather which prevailed in Ceylon during the first quarter of the year occasioned so rapid a growth of the leaf that production fairly outran the most sanguine estimate, and in consequence London became somewhat flooded with unexpected supplies, and a gradual shrinkage in values was the result."

"Can you tell me why China, which in 1849 monopolised the supply, now occupies in this country its third-rate place?"

"Well, China tea of the first quality is of a very delicate flavour and very fine drinking; but the proportion of that class of tea is so small that it is practically unobtainable by the general public, except at certain seasons of the year and at very high prices. The best of the crop goes direct to Russia, but the greater part of the growth is of very poor quality, and contains a very small portion which is soluble in water. It was owing to this deterioration of China tea which ensued, years ago, a demand for Indian tea, and, more recently, for Ceylon tea. Had China continued to be able to send tea of really good quality, and comprising the whole of its crop, we should probably never have heard of Indian and Ceylon teas. Then, too, the latter sell better, they go further, and, in a word, they are more economical. According to the Customs testing 1 lb. of China leaf will produce five gallons of liquid tea; but 1 lb. of Indian tea will give 7½ gallons, or 50 per cent. more."

"What have you to say of Sir Andrew Clark's condemnation of Indian tea, which he alleges disorders the nervous system, and produces a state of tea intoxication?"

"Ah! he did not say Ceylon tea! But the general mistake made by the public is to infuse Indian tea too long. It contains a much stronger body in the 'extract'—that is in the amount soluble in water—than China tea does. You obtain in five minutes' infusion of Indian tea perhaps as strong a cup as with ten minutes' infusion of China tea. Consequently, it is unnecessary to draw out the total strength possessed by the tea. Ladies should never allow Indian tea to stand more than five to seven minutes, and certainly not as long as ten to fifteen minutes. By the first method they would get the flavour of the tea without the tannin, because tannin is not so soluble in water as these constituents which give the quality and delicate taste."

"Does that advice apply also to Ceylon tea?"

"Speaking generally, Ceylon tea contains far more strength than Indian, and the same observations apply

in an almost equal degree. The public, in purchasing either Ceylon or Indian, obtain a great deal more for their money than they did when they brought China tea, and they do not require to use the whole of what they buy. Let me add that a 'cosy' is a very bad thing, unless to keep the tea warm after it has been poured into another vessel, which is the proper way to treat tea after it is brewed."

After this interview I thought it just to the representatives of the China trade that they should have the opportunity of explaining their position, in face of the threatened extinction of this old-established source of supply.

"Yes," said one gentleman—the best authority upon the subject—"there is no doubt that Indian tea has supplanted China tea; but at the same time there are some symptoms of a reaction which is attributed to the medical aspect of the question. You have seen what Sir Andrew Clark has said. Here is a copy of his address on tea, and here also, is the report of Dr. Hale White of Guy's Hospital, upon an analysis of Assam, finest China, and common Congou tea, with the result that he found in the Indian, after fifteen minutes' infusion, 17.73 per cent. of tannin, as compared with 7.97 per cent. in the best China, and 11.15 per cent in the common Congou. Dr. White adds: "The result is what might have been expected, as tannin is very soluble in hot water, and nobody who has drunk Assam, or any other Indian tea, and the choicest China, would require any scientific analysis to tell him which would be most likely to disorder the stomach and nerves. It is of course, true that any tea which has been infused for some time has a more marked effect than tea which has been infused a shorter time; but this difference is due not so much to the tannin as to strength. The moral, therefore, for persons with weak digestion is to select the best China tea they can get, and not to drink it strong; to be satisfied with flavour, and not to desire intoxication. They must be particularly careful, also, to see that the tea is not bleached."

"It is quite certain," continued the speaker, "that the deleterious property of tea is the tannin, and the less you have of it in the beverage the more wholesome it will be. You must bear in mind that it was not until 1859 that the consumption of Indian tea began to exceed that of China, although the Indian had been gradually displacing the latter for some years. Ceylon tea is of still more recent introduction. The doctors are beginning to differentiate between Indian and China teas, and to see there is a superabundant quantity of tannin in the teas from India and Ceylon, due to the mode of preparation. The public are not yet aware of it, and now you will never convert the masses; their taste is too degraded. No one who knows what good tea is will drink Indian. The Russians drink China tea only, and they have lately got it direct from the Ningchow District causing a falling-off in our exports. There is a divine taste. We, as people, are notorious for our coarse taste. Do not lower classes smoke shag tobacco? Now Indian tea is a pungent, strong, coarse-flavoured article, and it has been forced upon the public and popularised because it is 'British grown' and economical. But look at this tumbler. It is full of a muddy yellow liquor—that is due to the excess of tannin, for it is an infusion of Indian tea; but see this clear port-wine fluid—quite cold—that is China tea similarly prepared."

"Where can you get good China tea?"

"Unfortunately, owing to the course of trade, there is scarcely a shop in London where you can get good China tea; for they will tell you it does not exist. At their prejudice against it is that it requires much greater care in making, and the water must be just on the boil. You cannot expect to buy China tea such as is drunk in Russia under 3s per pound retail. As much as six roubles (12s) is given at Moscow for tea per pound, and the Russian pound is 10 per cent less than ours. Russia is taking an increasing quantity of the finest teas which China produces every year, and prices are paid for it which are beyond the English market."

"Is the China tea export to England doomed to extinction?"

"Everybody who enjoys a good cup of tea should hope not. There has been a further decline during the past year, it is true, the arrivals to May 31st next being estimated at ten million pounds less than the quantity to have during the twelve months preceding; but the shrinkage has not continued in a progressive manner, and is not so large as was expected. We hope the worst has been seen."—*Daily Telegraph*. No fault can be found with their representative giving the views of a China tea-dealer as well as those of Messrs. Gow, Wilson & Stanton; but it is ridiculous of the former to speak of 17.73 per cent "tannin" arising from 15 minutes' infusion of Indian tea. The simple answer, of course, is infuse only for 4 or 5 minutes and use far less of Indian or Ceylon tea and you can have as little tannin as suits your taste or as China tea yields! You see how Sir Andrew Clark is trotted out again to injure the reputation of Indian and Ceylon teas as compared with China. I got Sir William Gregory to promise this week that he would, along with Sir Arthur Birch, use his influence with their personal friend, Sir Andrew Clark, to give a fair trial to good Ceylon tea, properly infused, and to express an opinion which can be used to counteract the effects of his foolish speech as placarded in Regent Street and elsewhere. If this does not succeed, I must try to plan a "Ceylon Deputation" to sit on Sir Andrew and bring him to reason.

"The proof of the pudding is," however, "in the eating"; and as Mr. Leake put it to me the other day, the best answer to Sir Andrew and other fogies or critics, is found in the wonderful way in which Ceylon tea has gone into consumption during the past year. Still, however high the percentage of increase, it is possible 5 to 10 per cent more might have been gained, save for the foolish utterances of Sir Andrew and others deterring those who may pay attention to them.

Here is another paragraph on our teas which appears in the *Daily Chronicle* and two more from the *Daily Graphic*, a very enterprising journal to which Col. Howard Vincent is contributing letters:—

INDIAN AND CEYLON TEAS.—Mr. C. S. Hicks (member of the Ceylon Association in London) writes:—With reference to the criticisms on tea now appearing in the press, I shall be glad if you will allow me, as the largest shipper of Ceylon tea "packed in Ceylon," to say a few words on the subject. Ceylon tea is produced from both the Indian and the China variety of the tea plant, and possesses very varying qualities. Some of the Ceylon tea shipped is very near akin to Indian tea, and possesses a very large amount of astringency, while other gardens produce tea in which the China characteristics are predominant; and in all Ceylon teas which are of any value at all flavour is the great characteristic, while astringency is notable by its absence. In Indian tea, on the contrary, there is a great absence of flavour, and a great predominance of astringency and thickness. China tea is practically out of the question for the ordinary consumer (who must really be considered), as the question to be dealt with is not what the connoisseur buys, who is able, out of a very small area, to make his selection by paying any fancy price he chooses to indulge in, but what the ordinary everyday people of this country are able to pay to satisfy a demand for a really good tea. With this end in view there is no doubt that Ceylon tea at any given price will beat any China tea that is offered both for flavour, for purity, and for absence of all forms of tannin in proportion to its strength. The one great test of tea which is available to everyone who is a tea drinker is the comparison of the infusion, and there is not a tea-taster in Mingoo-lue who would dare to contradict this. The leaf of all good tea, when infused, changes to a bright copper colour; absolutely bad tea, when infused, is of a black colour, or very dark brown.

—*Daily Chronicle*.

Lovers of "the cups that cheer but not inebriate" will learn, without any degree of pleasure, that there is likely to be a rise in the price of tea in the London market. In consequence of the early and most severe weather, the Indian tea crop season has closed with a considerable deficiency on the estimates. There will also be a falling off in the supply which was expected from Ceylon. This was expected to reach seventy millions of pounds, but the actual export is not now likely to reach sixty-five millions, if even that figure is reached. The monthly exports have gone down steadily from the unprecedented total of 7,075,000 lb. in June to 3,678,000 in November, the aggregate export for the eleven months being 60,379,000, so that supposing four millions be added for December, the total will be considerably short of sixty-five millions. The total to this country, both from India and Ceylon in 1891, will not greatly exceed 150 or 160 millions of pounds, so that with such figures, and in view of the unsettled state of China, there is the prospect of the favourite beverage in so many families being rather dearer.

BRITISH INTERESTS IN CHINA. BY COLONEL HOWARD VINCENT, C.B., M.P.

II.—TEA AND OPIUM.

TO THE EDITOR OF THE "DAILY GRAPHIC."

Sir,—The staple export of China, and the one with which the Celestial Empire is most closely identified in the popular mind is, of course, her tea. In 1670 80 lb. of China tea were exported into England, and, despite export duties, varying in China and in the United Kingdom from 400 per cent on the productive cost, 100 per cent at the present time, the trade increased to 108,000,000 pounds in 1880.

COMPETITION OF INDIAN TEA.

Since then there has, however, been a serious decline increasing so much, from year to year, as to jeopardise the entire industry. This is declared to be mainly owing to the fortuitous development of tea planting in India and Ceylon,* and to the preference shown by the English consumer for tea of British growth. Twelve months after the Queen's accession, 400 lb. of Indian tea were sent to England as an experiment. In 1890 the consignment was over 100,000,000 lb., and Ceylon sent nearly half as much. The effect has been that, while in 1865, out of every 100 lb. of tea sold in England, 97 lb. were Chinese and only 3 lb. Indian, in 1890 the Chinese proportion had fallen to about 50 per cent, and the rest to the British tea drinker was also in a like degree reduced. One reason put forward by the experts, consulted by the Maritime Customs, is that "a good stout tea, that will stand several waterings, is what suits the mass of English consumers, and this India provides much better than China." The English merchants at Shanghai and Foochow affirm, however, that this greater strength is purchased by the retention of deleterious properties.

APATHY OF THE CHINESE.

It is in vain that the attention of Chinese cultivators has been called to the condition of the tea industry by all concerned. Moreover, four years ago, the Inspector-General of Customs thus addressed the Imperial authorities:—

"To a government, its people's industries must be of higher importance than revenue. I would, therefore, advise that taxes be remitted, in order that industries may be preserved. Think for the people, and forego revenue. Export duties ought to be light, in order that the surplus production of a people may go for sale elsewhere. Import duties, on the contrary, are the duties which ought to be retained; but the use to be made of each commodity ought to be well weighed. If it is something people cannot do without, it ought to be exempt from duty; but if it is a luxury it ought to be heavily taxed. On the right application of these principles depend the nation's wealth, and the people's too."

DECLINE IN EXPORT.

Nothing whatever has been done. From Foochow

the export has declined by one-half in ten years, and deprived the revenue of a million taels a year, and the people of five million taels in wages. The opinion is, indeed, general "that the gradual extinction of the China tea trade is practically assured, unless some thing ratards Indian and Ceylon production, of drastic measures are adopted."

The "Shanli," or hill tax, the "Likin," or war tax, and the export duty are all maintained intact, and the unfortunate Chinese growers have to compete with the untaxed tea of India and Ceylon. What distress is likely soon to ensue may be gathered from the fact that the production of one half only of the output of the Assam Company, with its few hundred employes, affords the main subsistence of 4,500 Chinese families, or, say, about 20,000 persons. They are themselves, moreover, so apprehensive that the introduction of the machinery in vogue in India and Ceylon will diminish employment that the Government has not felt itself strong enough to protect its use.

STAVELESS CASKS.

Have you heard of the new system of manufacturing "staveless casks" after the fashion described in the *London Times*:—

STAVELESS CASKS.—It is doubtless a matter of general knowledge that the bodies of casks and barrels are composed of a number of tapered staves, which are assembled together, held in position and hooped up. By a novel and ingenious method of manufacture, invented by Mr. Oncken, casks are now being manufactured from one piece of wood, and therefore without any staves, or, it may be said, with only one, the body constituting in itself a long, single stave. The method of preparing the body of the cask may be likened to the sharpening of a lead pencil by a pocket sharpener. The stem of the tree is first cut up into pieces or logs, of a length according to that of the harrol required, and is then hoiled for two or three hours in a closed vessel to soften the wood, a current of electricity being passed through the water the whole time. From the boiler the log of wood is taken to the machine, where it is held at each end horizontally between two points, much in the same way as a piece of wood is held in the lathe. Rotation is given to the piece of timber, which is advanced towards a broad blade fixed on a frame having a slot in it in a line with the edge of the blade, just as in a plane, which the cutting part of the machine may be said to resemble. As the trunk of the tree is revolved against the blade a continuous sheet of wood is produced of any desired thickness. The wood is drawn out flat from the rear of the machine by hand on to a table. The sheet of wood thus obtained is cut transversely into pieces each of the required length for one barrel. The pieces are then passed through a grooving machine, which cuts the groove in which the head is eventually fitted. Another machine cuts narrow V-shaped pieces at intervals out of the edges of the pieces of wood, which are then easily bent round into a cylinder and firmly hooped, the V-shaped slots enabling it to assume the necessary conical form at each end. There is thus only one joint in the body of the cask or barrel. The casks are afterwards dried in a special apparatus, after which they are ready for use. A factory is in operation in Germany manufacturing these casks, some of which we recently examined at the offices of the Oncken Patents Syndicate, 10, Old Jewry Chambers, London. We were also shown a model of the machine and some samples of wood of various thicknesses, including some exceedingly thin veneers.

LIPTON AND HIS TEA TRADE.

I am sorry to see no sign of the "Ceylon tea planter" or "tea estate proprietor," Mr. Lipton, doing anything to promote the sale of pure Ceylon tea: a deputaation to sit on him is perhaps more needed than on Sir Arthur Clark; for in the latest Lipton circular placed before me of "grand opening" of new branches, "Lipton, the largest tea dealer in the world," announces only blends 1s, 1s 4d, 1s 7d (the last of Ceylon and India) described:—

* How "fortuitous"? We are reminded of D'Israeli's "fortuitous concourse of atoms."—ED. T. A.

This is the finest and most delicious tea the world can produce, and is equal, if not superior, to what is sold by most tea dealers, and grocers at 2s 6d to 3s 6d per lb.

While on the other side we read:—

TO ALL LOVERS OF THE FRAGRANT BEVERAGE.

Mr. Lipton has pleasure in intimating to his customers and the public in general that the extensive purchases he has made in Ceylon tea estates enable him to supply the most delicious tea the world can produce, at prices impossible for any other tea dealer to sell at.

His estates, which cover many thousands of acres of the best tea land in Ceylon, are at an elevation of 5,000 feet, where nothing but the choicest teas are grown; and, to give an idea of the labour required in the cultivation and manufacture of tea on these estates, there are several thousand natives, independent of Europeans, constantly employed.

And then the opinions of the Ceylon press are quoted—and all to promote the sale of blends! Too bad this, I say.

STAINING CEYLON WOODS.

A correspondent asks us if we can give or obtain information for him relative to the methods available for changing or improving the colour of some of the commoner among the many varied woods that are locally available for furniture and other purposes. It is rather a coincidence that this request should reach us just as we were advocating justice being done to Ceylon's forest wealth in the structures for the distribution of tea at Chicago. The larger proportion by far of our more valuable woods must, of course, be excluded from any list of timbers to which the use of any staining material would be an improvement; but we think it will be admitted that there are some of the commoner descriptions that would be improved by the application of something of the sort. When writing this we have particularly in our mind the jakwood from which nearly all our commoner furniture is made. But we must except in this case one particular feature in regard to that wood. Ugly as its yellow colouring is when new, there is no wood that better repays in the course of time the application of what is known among energetic workmen at home as "elbow grease." If this most valuable of applications is bestowed systematically upon jakwood furniture, in the course of time it not only deepens the colour to a close resemblance to Spanish mahogany, but imparts to it a lustre which no other application could give to it. And the beauty of this "elbow grease" is that its effects are lasting, and may be revived with but slight effort after years of neglect and lying by. But, as our correspondent justly points out, it is not everyone who, being unable to afford the luxury of more expensive woods, would care to wait the result of this comparatively slow-acting though efficient agent. What he asks for is a suggestion as to how the results obtained by time and hard work may more quickly be secured. As to jakwood we may reply that the application of washes of thick lime water, of about the consistency of cream, will soon discharge the yellow colouring matter from the wood, and if, when dry after such application, boiled oil be rubbed on, or, better still, good varnish be applied, it will be very difficult to distinguish the results from those of a longer and more laborious process. We have seen the whole of the ceiling boards of an open Gothic roof so prepared (with boiled oil); and it was almost impossible to distinguish these in colour from the dark teak of which the principals of the roof were framed. Not long

ago too, in the case of new doors to a house in Colombo, a liberal use of varnish so changed the native yellow of jak to a handsome mahogany colour, that a planter who had never previously seen such a transformation was lost in surprise and admiration. By means of a ferruginous preparation too, jakwood can be stained so as very closely to resemble ebony. We are in possession of two book-cases which more than forty years ago were made and stained under the direction of the late Mr. J. I. Strachan. They have been in our possession some thirty-five years or more; and with only an occasional renewal of the staining on much rubbed parts in polishing, they have so passed for real ebony, that yesterday a member of our family was much amazed to learn that what he had all his life regarded as ebony was a jakwood imitation. We can understand that Ruskin would include such imitations in the same scathing condemnation with stucco trying to ape stone: the world in general, however, is not so particular as to the ethics of construction and colour. The one objection to ebony furniture is its ponderousness, an objection which does not apply to stained jakwood. Then again, *nadun* is one of those woods in constant use that may be brightened up and the tone deepened by the use of plain linsed oil, and this if well rubbed in will secure the permanence of the improved colouring. This wood, *nadun*, may be constantly used when thus darkened for the repair of English-made furniture of walnutwood, especially for such items as are made of the oft-used American walnut. That itself is an artificially coloured wood, and stocks of it lay for years reserved in the London timber yards, until it chanced to someone to find out a good medium for colouring and brightening the dull grayish-looking wood. We recently described the perfect harmony of a well prepared *nadun* chimney-piece with the walnut framing of a mirror. The darkened jakwood we have above referred to has also been used with great success for replacing large flat surfaces of mahogany veneer which so often succumb to the influences of this climate or to the damp of a sea voyage out from home. Further than these instances our own experience has not carried us, but there are probably many among our readers who could add to the list of native woods which would repay the application of artificial colorants. Possibly there are many of our more plentiful woods which might beneficially supplant the supply of jakwood, if means were known whereby their colour might be deepened or brightened. A series of experiments on specimens of wood supplied by the Forest Department, might be tried at the Government Factory, where, we understand, a substitute for jakwood, which is becoming scarce, is greatly desiderated.

A PARASTE.

His reception was threefold.

His ambition ludicrous.

His achievement wonderful.

Deceit No. 1—That he was only a creeper.

" No. 2—That his roots were in the ground.

" No. 3—That the leaves he bore were

Tea leaves

No. 1—He was a creeper inasmuch as a hang-mann rope is a cravat. No. 2—His roots in the ground might have been pulled up by a red ant; but to loosen his embrace of the Tea I had to insert my knife blade, and then at varying distances I found his creeping woody stem had white-roots of a quarter inch, gemlet-like imbedded in the Teawood. No. 3—In this he told so much truth that made it quite apparent he lived at a table other than his own, for the flatterer had found a soft place in warm-

hearted Toa and firmly seated throw forth an exceeding branch, leafed a rich waxy green, and was not this a most wonderful achievement? but how ludicrous his ambition since he could not "flush"! "What manner of thing is this?" asked the planter.

And Ternströmia shouted—"Loranthus, the murderer! he lives to rob himself by robbing us of our sap!"

"The juico he does. Surely botany is out of joint since I as a planter must needs turn chiroplast."

"A CRUELER."

The peculiarity of the loranthus is that it spreads over the stems and branches of trees and from the bark cells sucks out the life-blood, as the mycelium of *Hemileia vastatrix* does in the case of the coffee leaves. The leaves of this tropical mistletoe do not, however, so closely resemble tea leaves as the blossoms counterfeit honeysuckle. We have seen *Acacia melanoxylon* trees withered and jak trees dead from attacks of the parasite, but we never saw it on tea. It could only occur on a seed bearer?—ED. T. A.]

NOTES ON PRODUCE AND FINANCE.

THE STRENGTH OF INDIAN AND CEYLON TEA.—We may shortly see a discussion by correspondents in the Press on the respective merits and strength of Indian and Ceylon tea. This is not desirable, nor will it serve any useful purpose. A rivalry between Indian and Ceylon growers, if it should take the form of puffing and depreciating, is not desirable. For instance, Mr. C. S. Hicks, a member of the Ceylon Association in London, writes to one of the daily papers as follows:—"With reference to the criticisms on tea now appearing in the Press, I shall be glad if you will allow me, as the largest shipper of Ceylon tea 'packed in Ceylon,' to say a few words on the subject. Ceylon tea is produced from both the Indian and the China variety of the tea plant, and possesses very varying qualities. Some of the Ceylon tea shipped is very near akin to Indian tea, and possesses a very large amount of astringency, while other gardens produce tea to which the China characteristics are predominant; and in all Ceylon teas which are of any value at all flavour is the great characteristic, while astringency is notable by its absence. In Indian tea, on the contrary, there is a great absence of flavour, and a great predominance of astringency and thickness. China tea is practically out of the question for the ordinary consumer (who must really be considered), as the question to be dealt with is not what the connoisseur buys, who is able, out of a very small area, to make his selection by paying any fancy prices he chooses to indulge in, but what the ordinary everyday people of this country are able to pay to satisfy a demand for a really good tea. With this end in view there is no doubt that Ceylon tea at any given price will beat any China tea that is offered both for flavour, for purity, and for absence of all forms of tannin in proportion to its strength. The one great of tea which is available to everyone who is a tea drinker is the comparison of the infusion, and there is not a tea-taster in Minging Lane who would dare to contradict this. The leaf of all good tea, when infused, changes tea to a bright copper colour; absolutely bad tea, when infused, is of a black colour, or very dark brown." This reference to the absence of want of flavour and predominance of astringency in Indian tea is likely to offend susceptibilities without assisting the object of Mr. Hicks has in view. He might score off China tea to his heart's content without depreciating Indian tea.

A NEW YORK ANALYSIS OF CEYLON TEA.—A sample of the Ceylon tea sold in London at 53dols. per lb was, according to the *American Grocer*, submitted for analysis to J. F. Geisler, Ph.C., official chemist to the New York State Dairy Commission and the New York Mercantile Exchange. The result of the analysis of the Ceylon tips gave the following data:—Moisture (loss by drying at 100° C.), 6.20 per cent.; soluble ash, 3.77; insol-

uble ash, 1.53 (total ash, 5.30); theine, 2.54; total tannin, 22.79—total extractive matter, 43.40; insoluble leaf, 50.10 per cent. In the above data there is nothing particularly noteworthy, excepting that the per cent. of tannin is very high. An infusion of the tea was made by treating one part of tea with 100 parts of boiling distilled water and allowing ten minutes for the maceration. Under these conditions the tea yielded to water the following percentages:—Theine, 2.44 per cent.; tannin, 17.19; total extractive matter, 33.25; ash (total) 3.44; phosphoric acid (P₂O₅) in ash, 618 per cent. The alkalinity of the ash was equivalent to 1.798 per cent of K₂O. The infusion obtained was of a dark golden yellow colour, and had a very agreeable aroma and pleasant taste. From the above it will be seen that the infusion took up 96.6 per cent of the total theine, 75.3 per cent of the total tannin, and 91 per cent of the soluble ash, data characteristic of a fine tea.

BRAZILIAN COFFEE.—The Rio de Janeiro papers contain the following respecting the prospects for next season's Brazilian coffee crops:—"The delegates of the coffee factors of Rio de Janeiro appointed to organise the estimate of the coffee crops to be exported from this market now present their opinion relative to the 1892-3 crop. By much information carefully collected, it is known that in certain districts the blossom was fair, and that in others it was abundant, but generally only a small part matured, not only from the want of strength in the trees, already weakened by the delay in gathering the preceding crop, but also from the scarcity of labour and its disorganisation. With the data in hand, we think we may affirm that the crop in perspective should be estimated at about 3,000,000 bags, which figure is susceptible of modifications, according to the weather, up to the end of February. The delegates must also clearly point out that of the present crop, which appeared under favourable circumstances, a great part was not saved through the want of labour. This loss, which may be estimated at 500,000 bags of coffee, should be a sufficient incentive to furnish agriculture with a supply of useful and indispensable labour." A report on the course of the Rio de Janeiro and Santos coffee markets dated Dec. 8 is as follows:—"There has been a well developed struggle between exporters and factors, without a decided victory for either side. The former are apparently basing their campaign on the usual limited business in foreign markets during the approaching holidays and a consequent increase of stocks abroad, while the factors have in their favour the unsettled condition of the exchange market here. On the 4th instant, brokers advanced quotations by about 300 reis per arroba, since when there has been no change although it is easier to sell than to buy at the quotations. Shipments have fallen off, possibly because the November purchases are pretty well all on board ship, and receipts show some increase, from which results an increase of about 20,000 bags in stock."—*H. & C. Mail*, Jan. 8.

IF AN early mango crop foretells a season of drought, the prospects of the next monsoon are not bright. The royal fruit is already being hawked about Madras and can be bought for something less than two annas each. By careful cultivation it is possible, we believe, to have mangoes all the year round, but not often at the above price at this time of year.—*Madras Mail*.

THE SANITARY COMMISSIONER OF ASSAM has called the attention of Government to the fact that, owing to the absence of any system of conservancy in tea-gardens in that Province anæmia is spreading among the coolies. The malady known as *kala-azar* is also referred to the same source. The particular form of anæmia under consideration is said to be so prevalent that in one garden alone 36 per cent of the new coolies were found to be suffering from it.—*M. Mail*, Jan. 19th.

CEYLON TEA IN LONDON IN 1891.

We place below Messrs. Stenning, Inskipp & Co.'s review of Ceylon tea for 1891. In the past year, out of 59,708,000 lb. imported into London, the delivery was 53,486,000 lb. Prices had, however, unhappily gone down in proportion to quantity sent to the London market, from 1s 3½d for 59,921 packages in 1885, to 9½d per lb. for 755,562 packages in 1891. The reasonable hope now is that the large amount of our teas which have gone into consumption will create a demand at better prices. Poor China is likely to be driven out of the market, as at present the favourite tea is certainly Ceylon. Our deliveries were 53½ million lb. against 10 million Indian and 50,817,000 China. The percentages now are:—Indian 49; Ceylon 25½; total Indian and Ceylon 74½ against 24½ China. The latter figure is likely to become small by degrees and beautifully less.

THE COURSE OF THE MARKET.—A good demand at higher prices took place on the resumption of business, but in March, owing to indifferent quality, values receded until April, when an enquiry for teas "for prices" up to 11d took place; with heavy auctions in May the market gave way except for really good invoices; from June to August values for all but good Teas declined, the imports containing a large proportion of undesirable kinds. In September arrivals were of better quality, and more firmness was shown, the superior parcels going dearer; this position continued throughout October and November; the year closed firmly with an advance on all descriptions.

QUALITY.—The abnormal weather experienced during the greater part of the year in Ceylon caused a large yield of leaf, but at the cost of quality; still, a fair proportion of the Teas has been exceedingly good, and, in many instances, with fine flavour. The Imports generally have met a ready sale, their freshness and freedom from coarseness being in contrast with much of the China crop which it so largely supplants.

DELIVERIES IN 1891.—Although the supply has so rapidly increased, being 59,708,000 lb. against 40,612,000 in 1890, or equal to 49½ per cent, the Delivery has likewise shown a remarkable expansion, viz.: 53,486,000 lb. against 37,652,000 lb. in 1890, or an increase of 42½ per cent. The poor quality and comparative dearthness of so much of the China Crop have undoubtedly given a great impetus to the use of Ceylon growths, which, combined with Indian, are steadily forcing the produce of China out of the market; at all events, the preference on the part of consumers for Ceylon and Indian Tea is now so strong that it seems impossible China can recover any of its lost ground; on the contrary a further displacement is probable.

IMPORTS.—It is calculated that the area under cultivation is about 250,000 acres, and that the crop 1st January to 31st December 1891, will total about 67,000,000 lb., and in 1892 about 72,000,000 lb. The Imports have increased so rapidly, that it would be to the advantage of all concerned if Auctions were to be held more frequently in the week than hitherto, the one day and a part of another, as at present, compressing too great a quantity into that space. We would point out that much may be done by managers of gardens to ensure their Teas being more fully examined by buyers, by keeping the qualities down to four at the outside in each invoice, and thus making larger breaks.

INTERESTING CASE TO TEA-TRADERS.

FORGING A TRADE MARK.

Under this heading the *Overland China Mail* reports a case in which, on 30th Dec., 1891, at the Magistrate Ho Yip Chi, broker, was charged before Mr. Wise with having, on 19th Dec., falsely applied to certain packages or boxes of tea a trade mark purporting to be the trade mark of the Yuen Shun firm, of Canton, without the assent of the proprietor of the said firm. Mr. Ewens conducted the prosecution, and Mr. Pollock defended.

Inspector Stanton stated that some time ago he received a warrant for the seizure of some tea bearing the forged trade mark of the Yuen Shun firm. By virtue of that warrant he seized sixty empty tea boxes bearing the trade mark of another firm, thirty-five packages of tea bearing the trade mark of the Yuen Shun firm, fourteen bags of tea in the top floor of a house at 74 Queen's Road West. There were also three boxes containing some tea, some seals, and a number of stencil plates. The three boxes bore no mark.

When the tea and boxes had been at the Station a long time an application was made to the Captain Superintendent of Police for the fourteen bags of tea and the thirty-five packages. The application was for tea marked 'Yuen Sin' not Yuen Shun. The tea was not given up. Afterwards the Captain Superintendent was summoned in the Summary Court for the value of the fourteen bags of tea and the thirty-five packages. So far as witness knew nothing further happened till the defendant came and claimed the tea. He believed there was another application made before that, but he did not see it. He was present when the tea was delivered up to the defendant, who said he claimed it under a power of attorney. Defendant ordered the coolies to take the tea back to the house where it had been seized.

Inspector Haddon stated that he arrested the defendant by virtue of a warrant. He asked the defendant if the tea was his, and the defendant answered in the affirmative. Witness then produced the warrant, arrested the defendant, and seized the tea. He seized the whole thirty-five packages of tea, one of which was produced in Court.

Chi Yu Tin, the complainant, stated that he was the master of the Kweng Mau Tai shop in Hongkong. He was also a partner in the Yuen Shun firm and was their agent in Hongkong. The firm had been in existence for 22 years. Its headquarters are at Honsan, Canton, and the firm dealt only in teas, making specialties of two kinds. This kind was known as Wan-loo tea and it was principally sold in America. Shown labels—These were not the labels of his firm. They were imitations. Shown box—That was not one of his firm's boxes. He was sure it was an imitation. The trade mark was not put upon this tea with his consent. It had been put on without his knowledge. Shown wrappers of small parcels of tea—These seemed to be the same as these used by his firm. There was only one shop in Honam bearing the name of the firm.

Cross-examined—He knew the tea produced was not from the Yuen Shun shop because the characters on the wrappers were not identical. It read the same, but the shape of the characters was not the same. The strokes on the imitation were very thin whereas the strokes on the genuine wrappers were thick. The imitation could not possibly have been issued by the Yuen Shun shop. After a minute examination of the wrappers, witness pointed out that the real wrappers and the forged wrappers could not have been printed from the same stamp. The Yuen Shun firm had only one stamp, which they had been using for several years. They had no duplicate.

Mr. Pollock submitted that the case for the prosecution had broken down, as the only thing that had been proved was that the defendant got the tea under a power of attorney.

Mr. Wise said it was his opinion that there had been an attempt to swindle. This Cheun Yuk Pan was apparently guilty and he was trying to get the tea out by means of the defendant. He was not

going to convict the defendant, and if the principal did not come down from Canton within a reasonable time he would order the sale of the tea.

Mr. Ewens said he did not care whether his Worship convicted or not, so long as they retained possession of the tea.

Mr. Wise (to Mr. Pollock)—If you don't produce the real owner I must sell the tea.

Mr. Pollock maintained that his Worship had only power to forfeit the tea after conviction.

Mr. Wise—Oh, oo. Are you going to find the owner? (a laugh). Under the circumstances I will discharge this man, but what I propose doing now is to give you time to produce the real owner.

Ohu Yu Tin (re-called) stated, in answer to Mr. Pollock, that the trade mark of his firm had never been registered.

Mr. Wise—I don't mind telling you my opinion of trade marks in this Colony. Registration of trade marks is absolutely worthless for trade purposes or otherwise. However, all I am going to do just now is to acquit your client. I suppose you will not raise any objection to that.

Mr. Pollock—Oh, no, but I want the tea back.

Mr. Wise—But I will not give it to you.

Mr. Pollock—My objection is that as the trade mark is not registered in this Colony the tea ought to be given back. There is no charge in respect of the tea itself, and therefore the police cannot detain it.

Mr. Wise—I overrule that objection.

This concluded the proceedings.

A RETROSPECT OF THE TEA MARKET.

It is well that planters should sometimes see the position of tea as dealers view it, and we, therefore, give at some length the following summary of the tea market as it appears in the *Grocer*:—

"The world is full of surprises, and seldom, if ever, has this trade shown such fluctuations in value as in 1891, or such an upset in calculations as to stock at the end of the season. We began the year 1891 in the best of spirits as far as the market and importers were concerned. Trade was good, and deliveries for both home consumption and also export were on the increase. Supplies from China were much curtailed. The Indian crop 1890-91 failed to give the estimated extra 10 million lb., and instead we received only 100 million lb., or say one million lb. less than the previous season. Everything seemed to favour a big rise and absolute scarcity of supplies, as the retailers nearly to the end of 1890 had been only buying Indian teas from hand to mouth. The opening of the market in January, 1891, was buoyant at a material advance over rates obtained before Christmas. By the end of January a telegram was received from India that the export would be under 100 million lb., and prices went up with a bound. Quotations for China tea soon went up to 8d, and Indian tea to 10½d per lb. in the spring. All dealers' stocks were being bought up, until they refused to sell any more of their Indian stock. Importers were eager sellers all through, and many could not understand it, as it looked as if there would not be enough tea to go round up to the end of the season. Some large 'bear' sales of China tea soon broke that market, the 'bears' importing some big lines of Moning from America. Unluckily for China tea, export orders, which had been so good for the first half of the season 1890-91 (June to December), fell off from January to June, 1891, to the extent of nearly 4 million lb., and this fact, together with the extra supplies from America, helped to weaken the position of China terminals. Common Congou itself was scarce, but better teas had to be forced off as the end of the season drew near, so that Canadian shippers got teas at their own price, and the trade were able to fill their most modest requirements at fairly low rates. Indian teas were however considered to be in a far better position, and holders were quite confident that the trade would have to take their stock, as Indian teas could not be replaced by any other kind. Mixers and retailers decided otherwise, and Ceylons coming in

freely and at a lower range of prices, they were so freely used that their consumption increased nearly 11 million lb. for the first five months of the new year, while Indians fell off considerably. Dealers, therefore, got hung up with some very dear China and Indian stock, and their losses have been very heavy. Since the beginning of the new season (1891-92) supplies have been coming in so heavily from all three countries that they have far outstripped demand, and, whereas we commenced the season with 8 millions less stock than in June, 1890, yet as the year closes we have 10 to 12 million lb. more. China has sent us this season a full supply from Hankow of very high-cost Ningchows; the trade took a little, with a fair quantity of Kintucks, but unluckily the Russian famine has stopped all buying of high-priced teas from this market, and the consequence has been smash-out sales of all the good and choicest Ningchows at losses of from 6d to 1s 6d per lb. to the importers in many cases, or cent per cent on dealers' early purchases, some of which they still hold, whilst Kintucks can now be bought at a drop of 4d to 8d per lb. It will thus be well understood why the wholesale dealers are so depressed, coupled with the fact that they are losing a very large portion of the retail trade, owing to the enormous business some of the packet and co-operative societies are doing, and who buy direct from the market. 'Out of evil comes good,' they say, and if only the low prices of fine China teas attract the public attention, it may be the means of rehabilitating China tea for home use. Our most eminent doctors recommend it for nervous people or for those with weak digestion, and on the strength of Sir Andrew Clark's lecture many of the leading retailers find this a favourable opportunity to introduce a fine China canister at a moderate price. It may succeed with the few, but no doubt the 'million' will continue to prefer the stronger Assam and Ceylon growths for some time to come.* Speaking roughly, we may say we have had, from all quarters, inferior teas to deal with this year; and this, together with the heavy supplies up to date, accounts for the very low rates that are now ruling. Home deliveries for the last few months have been splendid, with increase upon increase throughout the year. Export, which showed an increase at the end of the year 1890, fell off from January to June, 1891, some 4 million lb.; but, curious to relate, this second half of the year, which takes in the 1891-92 crop, is very little behind when compared with the similar period last year, although there is supposed to be no demand for Russia, while the Continent has also wanted less owing to larger direct imports. As regards the small falling off for export from June 1 to Nov. 30, we find from Messrs. Gow, Wilson, and Stanton's circular that the export of Indian has increased 1,000,000 lb., and Ceylon 600,000 lb., or nearly double what it was last year in the same period. It is most difficult to see ahead, or try to give any advice. Prices are very low and look as if they must have touched bottom; nevertheless stock is rather heavy, and Ceylon promises to give us a further large increase next year. All these increased supplies from India and Ceylon are at the expense of quality; but the trade do not want all this common rubbish.

CHINA TEA.

The total import from China for the season is expected to be about 60 million lb., or 10 millions less than last season. No doubt we shall require it all, and still be able to use up some of the old stock, as we delivered 81½ million lb. from June 1, 1890 to May 31 1891. At the rate we are now delivering, we must reckon a falling off of some 12 million lb., thus showing a need of say 69 million lb. for the season ending next June. Total stock on Jan. 1, 1891, was 94 million lb., against 106 million lb. in 1890.

INDIAN TEA.

Consumption was very much checked by the high rates ruling for the first six or seven months

* And for all time. Persons of commonsense know what is good for them better than does an utterer of rash rubbish like Dr. Andrew Clark.—*Ed. T. A.*

of the year, but the low prices of the last three months have again given them an impetus, and when the figures are made up at the end of the year we expect deliveries will be just under 102 million lb., or say, 1 million lb. less than last year. The total import for 1890-91 season was just under 100 million lb., so that there was some justification for a rise at the beginning of this year. Unluckily, speculators rushed in and raised prices so high that they drove the teas out of consumption, and got left high and dry with stock they had to take 2d. to 3d. per lb. loss on, whenever anyone could be found to relieve them of their burden. The year opened at 3d. to 1d. per lb. advance, with a splendid demand for teas for price, say 9d. per lb., while Pekoes were also 1d to 2d per lb. higher at opening. Merchants offered their teas as fast as they could, but prices continued to rise right up to the end of April, until 10½ was reached for typo grade, but good and stylish Pekoes only brought 3d to 1d per lb. more. At the beginning of May undesirable teas began to waver, and from then onward prices dropped steadily, and holders were glad to find buyers at any price, so that by the end of June 8½d was about the quotation for Pekoo Souchonga, and Pekoes only a little better. It will be remembered that the crop of 1890-91 was not so good as that of the previous season, while the present crop is still worse; the bulk is thin with no point, and more than half of the supplies up to date (say two-thirds of the crop) has been sold under 8d per lb. One exception must be made, and that must be for Darjeelings—some of the better teas this year having fine flavour and bouquet, whereas last season they were dull and pointless. Teas under 9d per lb. are now from 1d to 2d per lb. cheaper than at this time last year, but good liquoring pekoes about 11d to 1s2d of which we had an over-supply last season, are quite 1½ to 2d per lb. dearer quality considered. Fine teas are again very scarce and realise extreme rates. The new season's have come forward very fast, and we have already had some 10 million lb. more than last season to date. The new crop is now estimated at 108 million lb. for this market so that we have already had more than the surplus. Prices are temptingly low, and there are already symptoms of higher prices. The first of the new season's came of in July very poor and thin, from 7½d to 8d for pekoes and pekoe souchonga, and old teas were being used instead, as showing much better value. Sales got very heavy in September, and common and undesirable teas were quoted easier every week up to the beginning of December, when there was a sudden rise of ½d to ¾d per lb. On the other hand, good-liquoring and finer teas continued to improve in value and were well competed for at full prices and at over last season's rates, the rise in good Pekoes and Broken Pekoe being 2d to 3d per lb. between September and the middle of December. Before the end of the year dealers had got rid of all their old stock, and the feeling was much more hopeful, as there was a large trade doing, and a very healthy, firm market. Stock on January 1st, 1891, was 36½ million lb., or 1½ million lb. less than January 1st, 1890, while the season ended on May 31st with 26½ million lb. stock against under 27½ millions in 1890.

CEYLON TEA.

Is unlike the 'faded beauty,' that is put on the shelf when youth and freshness are past. No rival can yet replace her, although the true rich Ceylon flavour is seldom to be met with now. The bulk of this year's crop has been very poor, and many of the teas have been raw and coarse-burnt, and often characterised as 'Indian kind.' Quality varies several times a year and often a fall of 2d. to 3d. per lb. in certain marks is no fall at all, but only an allowance for the difference in quality. Ceylon, like all powerful and successful people, is hated by its rivals, and one often hears the wish expressed that the wretched little island were at the bottom of the sea. The public are infatuated with Ceylon tea, and they never seem to grumble, although quality so often falls off. The growth of consump-

tion this year is enormous, viz., over 15 million lb., or say 10 million lb. since June 1. The total import for the year will be about 60 million lb., and delivery about 54 million lb. Next year they talk about sending us some 78 million lb., but if quality continues to decrease as quantity increases, the day will not be far distant when they will have nailed up their own coffin. Prestige will not last for ever. Prices now, as compared with the same time last year, might be summed up as follows:—Souchonga, Pekoo Souchonga, and low-priced and inferior liquoring broken are quite 2d. per lb. lower, good Pekoes 1d. to 2d. per lb. lower, while good liquoring broken Pekoes and finest lines are dearer and very scarce, although at two or three periods of the year they have been 2d. or 3d. per lb. dearer than at present. The year 1891 opened with an advance of ¾d. to 1d. per lb. for low-priced teas on the closing prices of 1890, and a good trade was done up to the beginning of March at always improving rates; sales then became large, and, with small trade demand, ½d to 1d drop in teas for price, 1d to 2d drop in Pekoes, and 2d to 3d drop in Broken Pekoes was registered by the end of April. During May another drop of 1d per lb. was noted. In June and July supplies were very heavy, quality very bad, and few teas to be found with any true Ceylon flavour. Souchonga were quoted at 6d to 6½d, Pekoes at 7d to 8d, and Broken Pekoes at 9½d to 10½d, but fine liquoring broken were dearer than ever, and selling from 1s 5d to 1s 10½d per lb. Prices then kept steady, although with heavy supplies, for another month or so, when they began to fall off; quality began to improve, and prices distinctly rose up to the end of the year for all but common rubbish, which kept Indian, while even this class suddenly improved about ½d per lb. at the middle December sale. From some of the foregoing remarks we do not wish it to be inferred that we disparage Ceylon teas. When they are good we think they are the perfection of tea—they are most necessary in blending with China tea, and the two go well together, as China tea tones down the rather too highly-flavoured Ceylon growths. As long as quality keeps fairly good we do not think that any tea will supersede it. China it has almost killed, and India, no doubt, is suffering from its competition. Let us only hope that her output may increase on account of new ground being brought under cultivation. This year the increase has principally been brought about by the heavy rains and early flushings, which had the effect of producing a heavier but coarser crop. This year has been noted for several sales of small lots of golden and silver-tipped teas—the extravagant prices realised were, however, more of an advertisement, and not a representation of actual value.—*H and C. Mail*, Jan. 8th.

NOTES ON COORG.

The administration of Coorg during 1890-91 does not call for much notice. The total revenue under all heads came to Rs15,958, and the total expenditure to Rs67,823. There is an increase observable both in revenue and expenditure, the latter of which was due to the cost of the new Survey Department. Survey Works seems to have been energetically pushed on, and though men had to be procured and instructed, the skeleton survey of 278 villages, having an area of 592 square miles, and the cadastral survey of 165 villages, having an area of 276 square miles, was completed at a cost of Rs49,793. Great success is reported to have attended the training of local men as measurers, and nearly all the subordinates of the Department are now Coorgs, who have worked well, while their employment has done a great deal towards lessening the unpopularity which the survey was at first threatened with. The increase in revenue was chiefly contributed by the forest department, the sandalwood sales being unusually successful. The year's harvest was poor; the rice crop was generally a light one, and in some places nearly a complete failure while the coffee crop was only 2,129½ tons

against an average of 3,557 tons. The cardamom crop was not quite so bad as the previous year, but still a poor one, and as the low prices continue, the growers of this product are becoming much impoverished.—*Madras Times*, Jan. 20th

(From our own Correspondent.)

COORG, Jan. 15th.—There was a harvest thanksgiving service held in the Polli-Betta Church on Sunday, the 10th inst., owing to the almost phenomenal crops that are being picked in the South Coorg District this season. Nothing like it has been seen for several years past, and with the present prices ruling in the market the losses of bad seasons will in some measure be recouped. The Rev. Mr. Malden conducted the service. In the case of one estate I hear the estimate was only 10 tons, but over 30 tons were picked off it, and there was still a little left. The estimate on another place was 20 tons, and nearly 40 was picked off it. The like stories come from almost every quarter of the District. I have also heard that in some places they ran so short of water for curing purposes that coolies had to be employed to carry up water in pots to wash the coffee. This could not have been very satisfactory, and I am sure the planters concerned would have been really glad if some heavy showers had fallen to help them in their difficulties. The water running short can only be accounted for by the heavy crops that had to be cured, as I believe the rainfall in the District this season exceeded the average by about 10 inches. The crops in North Coorg will not, I am afraid, turn out as well as the South Coorg ones, but it is hoped that they will all be paying ones. Of course there are several exceptions, where crops will be large. I think the reason why the crops in North Coorg were not quite so large as those in the Southern District is owing to the fact that while South Coorg was having a bad time of it during the past few years North Coorg has done fairly well. I one day visited an estate where there was a very good crop, and where the trees were looking in prime condition in spite of being heavily laden with berries. The proprietor, who was with me, pointed out a field off which he said he had on a former occasion picked 15 cwt. an acre during the second picking. I almost felt as if a Royal salute was being wafted in the breeze to me and that a Guard was presenting arms when I heard the statement.

Your Nilgiri correspondent's remarks about the colour of coffee have been most opportune. Every care should be taken to prevent coolies from picking half-ripe berries; but it sometimes happens that in spite of the strictest supervision some of them will bring in unripe fruit. I was surprised once to hear a planter of very large experience say that half-ripe berries made no difference whatever in the colour of the beans. The usual mode of curing coffee in Coorg is to have it pulped directly it is brought in the evening. The pulper most in favour is Gordon's fluted barrel breast pulper; others are also used, such as the disc pulper, etc. Directly the coffee is pulped it is allowed to ferment for from 36 to 48 hours. It is then washed thoroughly and placed upon drying tables, where it remains for 3 or 4 days prior to being removed on to the barbecues. It is dried in all about 8 days before it is despatched to the coast coffee works. Usually at this time of the year there is no dearth of carts and there is generally therefore no necessity for storing the coffee long. If it has to be stored it is frequently turned over and given an airing in the sun once in a way. In Ceylon, where the weather during crop time is most uncertain and rain continues to fall sometimes for six weeks at a time, the coffee used to be dried by what was known as the hot-air process in stores especially constructed for the purpose. This must have been highly expensive, but some of the planters there were of opinion that it was not a complete success. It need hardly be said, therefore that it was not generally adopted throughout the country. The drying tables referred to above are constructed in different ways. There is the rough and ready one,

which consists of forked sticks driven into the ground and covered over with a frame work of bamboos. Over this is spread coir matting and the coffee laid on the top of it. The breadth of these tables generally varies from 3 to 6 feet. Permanent tables are constructed in the following way. Brick-pillars are built at regular intervals, about a foot and a half square and about three feet high, and frame works of roppers and rafters are placed on the top of these when they are required for drying coffee on. When they are no longer required they are removed into the store till the following season. An ex-Ceylon planter called these tables "gims." The strangest part of it was that he used to go in for them himself.*

The coffee from Canon's Estates in Mysore has always held the highest place in the English market, and one year when prices were ruling very low everybody was surprised to note the very high prices obtained by Canon's coffee. This induced a planter here to obtain a sample bag of the coffee, to compare it with his own. No difference could be detected, with the exception that the beans were somewhat larger. It was then assumed that the estates being very old the coffee had succeeded in obtaining a good name for itself years ago, which it has succeeded in maintaining ever since. I remember reading an old copy of *Punch*, I think of the year 1866, of the estates being supposed to be offered for sale, and a Company was at once formed to purchase them. The whole thing was a mistake, which was all caused by an illegible signature of another proprietor who offered his estate for sale. Although the estates are now of great age they are still, methinks, in a flourishing condition, and are giving paying crops to the proprietors. The soil in that part of the country is, I believe, most excellent, and almost inexhaustible, while labour is also very cheap and obtainable, locally. The working of the estates costs very much less than it does in Coorg, where permanent gangs have to be kept, as directly work is finished on these Mysore estates the local labourers is dismissed till their services are required again.

Some years ago, when the price of coffee was very low, efforts were made almost on every estate in the country to improve the colour of the beans by drying coffee under shade for a few days before putting it out in the open. Although I heard from one or two places that this had resulted in obtaining for the coffee a couple of shillings or so in excess of ruling prices, yet it was generally believed that the drying of the coffee like this in no way benefited the beans in improving their colour. I think just about that time, or a little later, a gentleman in charge of curing works at Coimbatore wrote to your paper and said that the experiment had been tried years ago and the whole thing exploded. A good outturn at curing works really means a good price. The best outturn ever known was that of Dunkeld Estate, North Coorg, which one year turned out 79 bushels of parchment to the ton! I am indebted for this piece of information to the gentleman above referred to, who was in charge of the Coimbatore curing works. Some estates give a very bad outturn amounting sometimes to as much as from 93 to 95 bushels a ton. 88 bushels to the ton is very good, but in calculating the tonnage on the estate 90 bushels is usually allowed to the ton. There was a discussion at one time as to whether the beans of coffee grown in the open had greater weight than of that grown under shade, and I think it was decided that the beans in the former case had the advantage in weight.—*M. Mail*.

AMERICAN QUININE RUMOURS.

All during the Christmas week, says the *O.P. & D. Reporter*, there have been reports current in America that a combination of the European manufacturers of quinine was about to be accomplished. Details are lacking, but the trades seems to have put some faith in the reports as the transactions during the week have

* But what does "gim" mean? Contraction of "gimcrack"? The writer seems never to have heard of "Clerihews."—*Ed. T. A.*

been on a larger scale than at any time within the past six months or possibly the entire year. The most interesting feature of the rumours now current is that the Brunswick people, who have been heretofore aggressively opposed to the establishment of any understanding, have signified their willingness to co-operate with the other makers in an endeavour to improve the situation. According to the *N. Y. Shipping List* a London circular of December 11th says that it has been learned on excellent authority that a movement to combine the German factories is again at work. The proposed agreement may not be an international affair at the start, but the intention is doubtless to regulate production and realise better prices in the home markets. Some manufacturers abroad are reported as being very much surprised over recent developments and the fact that sellers have been offering quinine for the whole of next year at 9d. These offerings come from two different sources, and we thought to represent the concentrated efforts of certain parties who are trying to promote the combination idea by the usual method of bearing the market. Very little confidence is placed in the reports by members of the trade in America, with one or two exceptions. —*Chemist and Druggist.*

THE DUTCH MARKET.

Amsterdam, Jan. 7.

The cinchona-bark sales to be held in Amsterdam on January 21st, 1892, will consist of 4758 packages—viz., 4529 bales and 229 cases, about 417 tons, divided as follows:—From Government plantations 225 bales, 77 cases, about 2½ tons; from private plantations 4,304 bales, 152 cases, about 392 tons. Druggists' bark: *Succirubra* quills, 107 cases; ditto broken quills and chips 135 bales, 5 cases; ditto root 37 bales, 4 cases. Manufacturing bark: *Officinalis* quills 24 cases; ditto root 4 cases; *ledgerinna* quills 85 cases; ditto broken quills 239 bales; ditto root 867 bales. Hybrid broken quill 241 bales; ditto root 10 bales—total 4,529 bales, 229 cases.—*Chemist and Druggist.*

FACTS WORTH KNOWING.

Egg stains can be removed by rubbing them with common table salt.

To keep flies off gilt frames, boil three or four onions in a pint of water, then apply with a soft brush to the frames.

When whalebones have become bent, they may be used again by first soaking them in tepid water for a few hours, and then drying them.

Lamp-wicks must be changed often to insure good light, as they will soon become clogged, and the oil does not pass through them freely. A clear flame will be certain if the wicks are soaked in vinegar twenty-four hours before using.

When washing windows, looking-glasses, etc., be sure to put a little ammonia in the water. This will save labor, and clean them much more effectively, giving as well a much finer polish. For general cleaning, ammonia in the water will remove dirt, smoke, grease, etc., much better than anything else.

Do not wash combs unless absolutely necessary. Water will make the teeth split and the comb rough. Small brushes, which are made for the purpose of cleaning combs, are easily obtained at little expense, and with one of these the comb may be thoroughly cleansed, wiping well and following with a soft cloth afterwards.—*Good Housekeeping.*

NOTES FROM OUR LONDON LETTER.

LONDON, Jan. 15.

Certainly, if correspondence in the public newspapers may be accepted as constituting an admirable vehicle for the advertisement of Ceylon teas, you may be congratulated on the occurrences of the past week. It was only when last writing

you that it devolved upon me to notify to your readers several letters which had been published during the week then under review, and the past seven days have seen these still further added to. We believe that a letter from Mr. C. S. Hicks has appeared in more than one of the papers, but it has only been under my own observation in the *Globe* of the 8th instant. It was a very lengthy letter, far too much so far as to expect you to reproduce it *in extenso*, and therefore a reference to its general character will suffice for this letter of mine. Mr. Hicks's communication is headed "Facts about Tea," and in it he describes himself as being "the largest shipper of Ceylon tea packed in Ceylon." We understand that this claim is somewhat disputed, but with such a difference of opinion we need have nothing to do. The whole intent of what Mr. Hicks wrote was to disparage China teas as compared with those of Ceylon; and what he has written for public instruction is forcible enough and calculated to do much towards nullifying any prejudices which may have been awakened by Sir Andrew Clark's late unwarrantable and injudicious utterances.

Mr. Hicks's letter was followed up in the *Globe* of Tuesday last by further letters written respectively by Dr. N. E. Yorke-Davies and by a gentleman who subscribes himself as a "Tea Planter of Thirty Years' Standing," the identity of the latter being unknown to me. It can only be said of the last two letters that they form the clinching of the rivet driven home by that of Mr. C. S. Hicks. The perusal of them cannot be pleasant reading to those in the China tea trade, who year after year see their business narrowing more seriously in its dimensions.

The Brokers' Association is to hold a meeting today to finally discuss arrangements for availing themselves of the further accommodation granted by the Committee of the Commercial Sales Rooms for the auction of Ceylon tea. The proposal to be considered is that, from the beginning of next month, the sales of such teas shall be continued throughout the whole of Tuesday and Thursday in every week. Former letters of mine have told you as to possible difficulties arising out of the necessity some firms may be under of appointing an additional buyer to meet the new arrangements; and these, if they are considered serious, will probably find expression at today's meeting. From all that has been told to me it does not seem to me to be likely that any such possible objection would be allowed to overrule the manifest advantage the newly-conceded arrangements must prove to all and everyone concerned in the trade.

The necessity for these being conceded was very strongly evidenced by the sale of Tuesday last, which was the heaviest Ceylon auction as yet held in London, there having been no less than 20,047 packages offered. In spite of this large quantity being available, the price was well maintained throughout, and one seller informed me that though he had come the last on the list of the day's auction, the whole bulk of his tea sold for a halfpenny over valuation.

It has been told me that at the meeting of the Ceylon Tea Plantations Company, the proceedings at which were reported by my last letter, Sir William Gregory expressed himself as the most determined opponent to the project for undertaking coffee planting in Perak. Indeed, your former Governor appears to have been quite excited in his denunciations of this now abandoned scheme, he declaring that, had he believed any such investment out of Ceylon would ever have been contemplated by the directors, he would not

have touched the shares in the Company he had accepted in part payment for certain estate property he had sold to it "with a pair of tongs." Those who saw Sir William Gregory on that occasion tell me that he looked dreadfully ill and worn; and he himself confessed that his attendance at the meeting was strongly in opposition to the counsel of his doctor.

Mr. J. L. Shand did not take the mana grass tea box with him, but it has been shipped this week per "Manora" for conveyance to Ceylon to be delivered to him there. You will therefore soon be afforded the opportunity of judging for yourselves of the value of the mana-grass board for manufacture locally into articles of this nature, and of its possible applicability to even more extended purposes.

Mr. Elwood May has just sent home another specimen of the advertisements of his Tea Company that he has had inserted, under the arrangements formerly detailed to you, in the American papers. This one is contained in a paper called *The Stage*, a journal which is devoted to a record of all connected with theatrical matters, and is undoubtedly one of the best specimens of specialist newspapers we have ever seen. The advertisement is very much in Mr. May's customary style. For one of its headings it has "Ceylon Tea Aids Nutrition of the Nerves." It gives at length a highly eulogistic letter written by Mr. J. A. Boureghier, M.D., of New York, a specialist in diseases of the nervous system, in which he says that, after extended trial, he recognizes the enormous value of Ceylon Tea in dietetics, and that he is able to permit its use in the case of numerous disorders in which he had previously forbidden the drinking of tea at all. He further wrote:—"Ceylon tea aids nutrition of the nerves, and thus is not only free from injurious effects, but is beneficial as a beverage." The advertisement also quotes from Dr. Yorke-Davies's book entitled "Food for the Fat" published in London some time back, in which the use of Ceylon tea is recommended. These quotations are followed by a notification that Ceylon tea furnishes "a cup that cheers with after cheer is what an actress needs. She will find this in our Pure Ceylon Teas, Blend, Tiffin and Bungalow." The advertisement concludes with the announcement that the capital of the Company is 1,000,000 dollars, but it does not state how much of this is paid up.

EXPORT OF TEA FROM JAPAN.—During 1891 Japan exported between three and four million more pounds of tea than in 1890.

INTRODUCTION OF THE BIRCH TREE INTO CEYLON.—Some time ago we mentioned that we had been favoured by our good friend Mr. Gammie of the Sikkim cinchona plantations with seeds of a Himalayan birch, which he described as rapid in growth and as yielding a wood excellent for fuel purposes. During our recent visit to Abbotsford we found some plants so well advanced that we cut a couple of twigs from one, which, as specimens, we sent to Dr. Trimen. In response the Director of the Royal Botanical Gardens writes:—

"Peradeniya, Jan. 4th, 1892.

"I am so glad to see the Birch, the first in Ceylon. I suppose it is *Betula utilis*; the name refers rather to the bark, which is greatly used, than to the wood though that is good also. I hope the 'Birka' of Abbotsford will thrive as those of Aberfeldy." Not having Mr. Gammie's letter to refer to, we cannot recall the specific name he gave, but Dr. Trimen's guess may be correct; although, on referring to Gamble's Manual of Indian Timbers, we cannot find *utilis*

amongst the *Betulas* described by him, which are *Acuminata*, Wall., *alba*, Linn., *Bhojpattra*, Wall., *cylindrostachys*, Wall. *Jaquemontii*, Spach., and *papyracea*, Willd. The only one of these described as of fast growth is *Betula cylindrostachys*, which grows on the Darjeeling Hills and is used only for fuel and charcoal purposes, for which it is very good. It is described as an extremely handsome tree with drooping branches. In this latter characteristic it resembles the exquisitely beautiful birches of the Scotch Highlands. As yet our specimens show no signs of the drooping tendency, but we hope they will take it on when further advanced. Meantime, some of the *Eucalypti*, "red gums" especially, grown on Abbotsford and other upcountry estates are very beautiful substitutes for birches, in their drooping branches and fine foliage. If, as Dr. Trimen indicates, our birches are the first grown in Ceylon, it is something for Abbotsford to be proud of. There are English oaks, one of which has horn acorns, and seedling Assam oaks (*Quercus serrata*), to keep them company.

ELECTRICITY IN OYSTER CULTURE.—It might be thought that electricity would be about the last adjunct to employ in studying the culture of the succulent bivalve. An application of it, however, has recently been made by Mous, Lacaze-Duthier, the well-known authority on oyster culture. He makes use of the electric light in examining the stages of development through which the spawn passes. A glass cylinder is mounted in a cylindrical skeleton cage which serves as a support; into this glass the water containing the spawn is placed. At the bottom is a plane, silvered reflector; the cover forms a parabolic reflector, in the centre of which is fixed a small incandescent lamp. The reflectors and the sides of the glass cylinder act in such a way that but few rays of light emerge from the apparatus directly; hence the liquid is suffused with a soft illumination which is admirably suited to the examination of the contents. This little apparatus, or a modification of it, is now being employed in various researches into the life processes of ferments and the culture of microbes, the illumination by the incandescent electric light being much more suitable for the study of these low forms of life than that from other artificial sources.—*Electrical Review*.

THE DIAMOND-BACK MOTH CATERPILLAR may be an object of interest to entomologists, but market gardeners regard it with unconcealed suspicion. Last July, swedes, turnips, and cabbages in various districts of the eastern parts of Yorkshire, Lincolnshire, and Norfolk, and Scotland were infested to an extent which excited great apprehensions on the part of the growers and attracted the attention of the Board of Agriculture. Mr. Charles Whitehead, F.L.S., was commissioned to prepare a special report upon the pest, and this has just been issued as a Departmental Paper. Mr. Whitehead shows that as long ago as 1859 this moth was known by turnip-growers to be very mischievous, while during the last ten years it has made its appearance at many places in numbers which indicate an enormous multiplication of the species. Sir Jacob Wilson pointed out to the Royal Agricultural Society last July that although there had been every prospect of a large crop of turnips in Northumberland, the attack of the pest during the previous week or fortnight had reduced large tracts to a waste desert. Swedes seem to be a favourite crop, but cabbages have suffered still more. Mr. Whitehead concludes a comparison of the remedies that have been tried, by pointing out that the application of the mixture of soot and lime in good time with the Strawsonizer is the best; but paraffin, quassa, and carbolic acid are efficacious to some extent. Nitrate of soda and other stimulants have too been found useful in forcing the growth of infected plants. Prevention, however, is better than cure, and farmers should make a note of the important fact that it is most important to cut down in the spring cruciferous weeds, such as "charlock," hedge mustard, and prickly saltwort, which serve as breeding places for the first brood of moths.—*Daily Graphic*.

FROM THE METROPOLIS.

LONDON, Jan. 15th.

THE CEYLON TEA PLANTATIONS CO., LD.

Calling at the Mincing Lane office of the Company two days ago, I was fortunate enough to meet Mr. Rutherford, whom I had missed twice on previous occasions; but sorry to learn that Mr. Reid had left for Scotland the night before. The Chairman of the Company has, in fact, been far from well; he had a sudden and severe attack (connected with his Indian experience of dysentery), and had to cancel public engagements to speak at political meetings. He is now ordered to be very careful of himself or some time to come. Mr. Rutherford, on the other hand, is in robust health—stouter and ruddier than in the Ceylon days. He gave me the news that the proposal to invest some of the funds of the Company in coffee in the Straits was solely to meet the recommendations of their Ceylon Manager, Mr. Talbot, and by no means because Mr. Reid or he himself were eager for this addition to their business; indeed, if they had been, they could easily have outvoted the opponents led by Sir Wm. Gregory. But the suggestion was simply made to see what shareholders thought of it, and it was Mr. Rutherford who quoted my remarks at the Royal Colonial Institute on the good prospects before coffee at Perak. The *Financial World* of Jan. 9th has an amusing article on the meeting of the "Ceylon Tea Plantations Co.," headed "Tea vs. Coffee" with an illustration of the doughty chairman—(the future Unionist M.P. for Kinross-shire as we hope)—in full Highland costume in the act of pouring out the contents of a breakfast cup inscribed "Straits Settlements Coffee." The subscription to the engraving is "Mr. David Reid is compelled to abandon his coffee." The same journal, as Mr. Rutherford showed me, had, on 9th May last, a similarly amusing illustration on a meeting of the Ceylon Tea Company showing "how Mr. David Reid, Sir W. Johnstone and Mr. Shand enjoy their tea" sitting at the table. I mention so much; but I hope this mail will carry to you copies of the journals and "electros," so as to enable you to republish both notices for the edification and amusement of the numerous friends of those gentlemen in Ceylon. However, all concerned feel now that it will be best to keep the name of the premier Tea Company of Ceylon free of extraneous speculation or investments and if need be start a separate and coffee company specially for the Straits. When I say "premier," I think I am safe in speaking of the Ceylon Tea Plantations Company as the most important in Ceylon tea, but Mr. Rutherford tells me that the Eastern Produce and Estates Company has rather more acreage under tea, namely some 9,000 acres; but a good deal of this must be on old coffee-land I fancy.

TEA PRODUCTION AND CONSUMPTION.

One subject that came up with Mr. Rutherford was the probable export of Tea from Ceylon for 1892; he is inclined to take a very moderate view of the probable increase (some 7 or 8 million lb.), considering that the enormous rise in 1891 was due very much to a very exceptional season. But I pointed out the large additional acreage in our Directory planted between 1888 and 1889 (22,000 acres), and I fancy Mr. Rutherford will agree that less than 76 million lb. can scarcely be estimated as the total export from Ceylon this year. He is hopeful, I am glad to say, about the future of consumption, though he anticipates the possibility of even lower prices (by a shade) during the current year! Such a result could not fail to give the coup de grace to the China trade which,

indeed, no one expects to see assume its recent importance again, so far as the United Kingdom is concerned.

CEYLON TEA IN AUSTRIA.

It is very satisfactory to learn, officially from Mr. A. Philip, that the Tea Fund Committee are to consider and, if possible, act on some of the suggestions I made in reference to pushing the sale of Ceylon teas in Austria. I am hopeful that Messrs. Shand & Haldane will follow up their trade in Switzerland by endeavouring to supply the Karlsbad market. Meantime I am gratified to have in addition to Mr. Philip's, another letter of thanks from Mr. Charles Osswald, Winterthur, for what I wrote about Vienna. He is confident that the sale of Ceylon tea will become very considerable there, by and by.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, Jan. 16th.

CINCHONA.—The first auctions of the year took place on Tuesday. They were of small extent, but the assortment offered was a fairly good one. The catalogues comprised:—

	Packages.	Packages.
Ceylon...	483 of which	322 were sold
East Indian ...	600 "	600 "
Java ...	365 "	365 "
South American	266 "	265 "
African West Coast	210 "	167 "
	1,929	1,719

The assortment of bark was of good average quality, yellow and grey barks being very plentiful in it, while there were also 254 packages of Darjeeling bark from the plantations in Northern India. This shipment was well competed for, though the prices it realised show a sad falling-off on those which the Darjeeling planters were accustomed to obtain for their bark when formed a regular feature of the London auctions. For the comment the sales showed a decided improvement on their immediate predecessors, and as they neared their end competition became more pronounced. Nearly the whole of the bark offered was disposed of at an irregular advance, ranging from 5 to 15 (in some instances even 20) per cent over the price of the last London auctions. The unit now stands at 1½ to 1¼ per lb.

The following are the quantities purchased by the principal buyers:—

Agents for the Mannheim and Amsterdam works...	Lb.	112,624
Messrs. Howards & Sons	69,237
Agents for the Amerbach works	42,550
" " American and Italian works	38,680
" " Brunswick works	25,165
" " Frankfurt O/M and Stuttgart works	...	12,750
Sundry druggists..	...	40,850
Total quantity sold	...	341,765
Bought in or withdrawn...	...	40,635
Total quantity of bark offered	...	382,400

It should be well understood that the mere weight of bark purchased affords no guide whatever to the quinine yield represented by it; firms who buy a small quantity of bark by weight frequently take the richest lots and vice versa.

THE AMERICAN QUININE-DUTY.—From a statement in the *O., P. and D. Reporter*, it appears that the duty on quinine in the United States has been altered ten times since 1832, although the customs tariff itself has undergone about thirty revisions since that year. From July 13th, 1832, to Aug. 30th, 1842, the duty was 15 per cent *ad valorem*; it was then changed to 40c per oz. On July 30th, 1846, it became 20 per cent *ad valorem*; on March 3rd, 1857, 15 per cent; on March 2nd, 1861, once more 20 per cent; on August 5th, 1861, it was raised to 30 per cent; and on July 14th, 1862, to 45 per cent. There it remained for ten years until May 1st, 1872, when it was lowered again to 20 per cent. On July 1st, 1879, the duty was removed altogether, and since then quinine has remained on the free list.—*Chemist and Druggist*.

INDIA AND CEYLON vs. CHINA TEA.—The *London and China Express* of 8th Jan. says:—

Business in the Tea market reopened with good prospects, but the week closes with less buoyant feelings in view of the very large supplies of Indian in the public sales for next week. Fine China Tea, which at the close of last year was quoted at 9d to 1s, is still inquired for, but importers seem reluctant to sell and no wonder when the import cost is realised. There can be no doubt that the unfavourable position China Tea has now permeated through all engaged in the trade. Wealthy native (Foochow) tea-men are reported as ruined, and very few able to withstand the times. It is Red Leaf Tea that mostly feels the competition of Ceylon and India. In the palmy days of the trade Red Leaf commanded the best prices, whereas during the current season the so-called crack chops sold but a few pence per pound over common Congon. The question for the future now is, will Chinese produce a tea to equal the old standard of strength and delicate flavour combined. It could be done in the past when exchange averaged 4s 6d to the dollar, and why not now when the dollar is nearer 3s, and higher prices paid to the tea-men? Both Indian and Ceylon are increasing their supplies, the latter at a rapid rate; but judging from the low prices for inferior grades during the past three months, planters are anything but satisfied. What can be expected, however, when production is carried on at such hazardous risks?

DAVIDSON'S SIROCCOS.—In our issue of Jan. 4th was inserted a letter from Mr. John Ferguson, in which he stated:—

A story is current of the experience of one of the largest Calcutta firms in "tea" who had erected a great Central Factory with a wonderful array of Jackson's Rolling and allied machinery; but who, soon after substituted, at the instance of an ennobled manager, "Siroccos" for the other "driers," the object being to dry the tea at the low temperature which was to ensure keeping qualities, &c. The result, as the story runs, was woefully disappointing, namely a falling-off of 4d a lb. in the average (could part of this be due to falling markets?) so that now the Siroccos are to be cast on one side and Jackson's Driers taken on—only the little experience with the less price for tea and double experience about machinery and work, is said to make altogether a difference of £30,000 to the firm in question. Of course, they must be "princes in tea" to deal in such large figures even by way of loss. "I tell the tale as 't was told to me." Possibly there may be some modifications or corrections which may reach you from the "Sirocco" side and which you will, of course, as readily publish. The story, in an apparently authentic form, in letters from Calcutta, reached Colombo as well as London. But Mr. John Ferguson rightly judged that there was another side to it, and that we should, with equal readiness, publish it. A telegram from our absent confrère has reached us, in which it is stated on Mr. Davidson's authority that not only have none of the Siroccos been discarded but that more have been ordered by "the princely" Calcutta firm alluded to. It gives us great pleasure to do justice to Mr. Davidson, whom we regard as a great benefactor of the tea enterprise and of the tea planters. He and Mr. Jackson are both able and honourable men, and the competition between them as machinists, though keen, is conducted on gentlemanly and upright principles. The new draught Sirocco and Mr. Jackson's Britannia Drier have, each its own merits, and the planters of India and Ceylon are very fortunate in having two such men as the inventors of these machines devoting their experience, skill and scientific knowledge to providing the most perfect appliances for the manufacture of the tea leaf. We regret therefore that such a story as Mr. John Ferguson was told should have been invented and should have received currency in our columns. An explanation is due from those who sent the story from Calcutta to London and Colombo.

CINCHONA AND QUININE.—In a very long and interesting report by Messrs. Brookes and Green that has reached our (*Madras Times*) hands, upon the quinine and cinchona bark market for the year 1891, they give it as their opinion, after stating that they have followed the movements of the articles "week by week, indeed day by day," that the "stock of quinine in the world is less today than it was at this time last year"; and they go on to say that "notwithstanding all that has been written regarding the invisible quantities of quinine in second hands, we very much doubt whether the entire stock of both quinine and bark combined, not only in London, but other markets as well, would total up more than one year's consumption." They hold the view that the world's consumption equals the world's manufacture. If Messrs. Brookes and Green's conclusions be right, it would naturally follow that any diminution in shipments from Java, or any cause tending to even a slight increased demand for the drug, would have the effect of sending up prices of cinchona bark; and in the face of the very heavy recent exports from Java, the late rise in the "unit" to 1½d is very encouraging. It is very possible due to the increased consumption of quinine, consequent upon the recurrence of the influenza epidemic at home, and in the interests of planters it is to be hoped that the improvements in the value of bark will be maintained, if not in the near future enhanced. Java holds the key of the position, and if she would abstain from forcing her supplies on the market, the result would be better for her planters as well as for growers of bark in other parts of the world.

TEA FLAVOUR is discussed by Mr. John Stalkart in the *Indian Planter's Gazette* thus:—

Your late issue stated that the flavour of tea is obtained by drying it at a temperature of 130° Fahr. Flavour comes from two descriptions of tea, the China and the indigenous; it also depends upon the height above sea level, at which it grows. For this information I refer you to the oldest book we have on tea, Jacobson's Manual of Tea cultivation. The flavour of tea, and the aroma also, can be lost by bad manipulation, particularly in driving a large quantity of heated air through it, at the velocity of a tornado. Tea should not be dried in ten minutes as in the present mechanical process, but should be dried not quicker than in one hour and ten minutes at a temperature of 250° Fahr. Flavour and aroma are also lost in the process of bulking, and the grocer has only himself to thank if the tea does not come up to his expectations. A few years ago, he would not buy flavour tea: he only wanted some rasping senna variety obtained from hybrids, so that one pound would strengthen ten pounds of thrice infused China leaf. With his notions of making a fortune rapidly, he has done his best, to bring tea into disrepute. He insists upon it being bulked at the gardens, that is, tossed in the air, to get rid of its good qualities from exposure, that he may buy it cheap. He then has it bulked at the tea warehouses round about Tower Hill, which locality is not famous for its good odours. He then blends it with a lot of dirty faced China tea, and then wonders that the tea is not improved: and in his wisdom states that Indian teas will not keep, whereas he has only his own insanity to thank for the poorness of his blend. The China variety and the indigenous have two distinct flavours. The hybrids do not come up to them in flavour, though they give a strong bitter tea. Planters are much puzzled what seed to sow, as the brokers follow the lead of the grocers, and will not pay for flavour. The planter looks to his pockets, and sows only that which will pay him best. I do not pretend to teach my brother planters. Each man must judge for himself.

THE EXPORTS OF TEA IN JANUARY:
ESTIMATES FOR 1892 AND THE
TEA FUND.

The motive of the local "Times" in representing the tea exports of January 1892 at only 4,900,000 lb., a figure which was to be telegraphed to London from several sources, was to favourably affect prices in the London market. But surely harm rather than good will result, when it is learned that the figures in the Chamber of Commerce table are materially higher, viz:—5,125,866 lb. Again, our figures from the Customs, which include shipments in vessels that have not sailed as well as those which have actually departed, are still higher, viz. 6,217,302 lb., an excess of 620,180 lb. over the export in January 1891. The higher figures are as capable of transmission as the lower. We see that Mr. Rutherford is amongst those who do not anticipate any material advance in 1892 over 1891. His opinion is worthy of all respect, and we shall be only too glad to find our own estimate of 85,000,000 lb. excessive. We believe, however, that only the general adoption of really light plucking can bring about such a result, and we shall believe in all planters plucking lightly, when all planters recognize the duty of paying subscriptions to the Tea Fund on the basis of green leaf gathered. Of course, the finer the plucking, the smaller will the contribution be. But it is no use trying to dwell in a fool's paradise. The exports of tea from Ceylon, though not on the scale of 1890, are bound to increase for several successive years yet, as land comes into full bearing, and the true remedy for over-production is a contenance, with more energy than ever, of the efforts being made, by using the Chicago Exhibition and other means to open new markets for our staple. But such efforts involve large expenditure of time and thought and money; and we cannot understand how those who shirk the plain duty of bearing their part of the money expenditure, at least, can enjoy the blessing of a clear conscience or the hope of prospering in their enterprise.

THE SALE OF CEYLON TEA IN LONDON.

The Secretary of the Planters' Association sends us the following correspondence with the Secretary of the Ceylon Association in London on the above subject:—

(Copy.) Kandy, Dec. 18th.
The Secretary, Ceylon Association in London, 14 Mincing Lane, London, E. C.

DEAR SIR,—I beg to acknowledge receipt of your letter of the 25th September with enclosures which have been duly submitted to the Committee of the Planters' Association at a recent meeting.

I have now further to annex for the information of your Association copy of a resolution passed by the Committee on the subject of tea sales in London.—I am &c., (Signed) A. PHILIP, Secretary to the Planters' Association of Ceylon.

Resolution referred to.

"That this Association cordially supports the action of the Tea Committee of the Ceylon Association in London in taking into its consideration the necessity of more days being set aside for the sale of Ceylon tea in view of the heavy exports now going forward and the fact that it is, as now arranged, quite impossible for buyers to give the samples proper attention."

(Copy.) Kandy, Dec. 18th 1891.
To Wm. Leake, Esq. Secretary, Ceylon Association in London, 14 Mincing Lane, London, E. C.
Dear Sir,—I am in receipt of your letter of the 27th ultimo with enclosures which shall be submitted to the Committee at next meeting.

I have now the pleasure of to enclose demand draft on London for £60 sterling, in payment of the grant from this Association to the Ceylon Association in London for the year 1891, and would express the hope that cordial cooperation in all matters [having for their object the good of Ceylon may long continue.—I am &c., (Signed) A. PHILIP, Secretary to the Planters' Association of Ceylon.

Copy.
J. Mincing Lane, London, E. C., 15th Jan. 1892.
A. Philip, Esq., Secretary, Ceylon Planters' Association, Kandy, Ceylon.

Dear Sir,—I have to thank you for your letters (2) of 18th ultimo, and for the remittance of £60 as the annual contribution to the funds of our Association here. On its behalf I cordially concur in the hops expressed that the two Associations may long work together effectively for the good of Ceylon.

Our Tea Committee will, I know be greatly pleased at the resolution expressing approval of its action in the matter of the arrangements for the days for selling Ceylon teas. I learn that the Commercial Sales Room Committee has agreed to provide a separate room for the Ceylon sales on Thursdays, and that at an early date this arrangement will come into force. This should for a time relieve the pressure caused by the rapid increase in the quantities of your teas coming forward.

Permit me in conclusion to congratulate your Association on the astounding progress made during the past year by Ceylon tea in the Home trade. You will see by the Board of Trade returns that the consumption in the United Kingdom, of Ceylon tea has increased nearly 50 per cent on that of the previous year, while in both Indian and China teas there has been a sensible falling off in the Home consumption. For the first time too the figures for Ceylon exceed those of China, the excess being upwards of 1½ million pounds.—I am, &c., (Signed) WM. MARTIN LEAKE.

THE A LA CHINOISE.

We now publish the article we recently alluded to as published in the Java paper on the preparation of Java tea as China. The gentleman who has been good enough to make the translation for us writes:—

"Do you not think that in order to satisfy the tastes of the people in other parts of the world who still like China tea, it would be well worth while for some of the great companies to prepare "thé à la chinoise" for the purpose of cutting out the China article? There need be no kind of falsification or adulteration connected with the enterprise. The produce would be sold as scented tea. You see how tenaciously the Javanese and Chinamen in Java cling to the kind they have been accustomed to. The same feeling no doubt operates in some parts of Europe and in America."

In the Essay by a Nilgiri Planter which we published some years ago, full directions were given for the preparation of scented tea, and all the flowers useful for the purpose were enumerated. But neither in India nor Ceylon have scented teas been prepared on any large scale; and we suspect public opinion would condemn the imitation of a product which our genuine sophisticated teas are driving out of the market.

(Translated for the Ceylon Observer, by J. D. Y.)

FALSIFICATION OF TEA ON A GRAND SCALE AT CHERIBON, JAVA.

Contributed by A. G. Vorderman, Inspector of the Civil Medical Service of Java and Madura.

When in June 1891, during a voyage from Batavia in the steamer "De Carpenter" I passed the night in the Cheribon roads, I was surprised to see a considerable number of very large packages landed at that place, and was informed by the mate that they contained tea.

There could be no doubt that something mysterious was connected with this article packed in the way it

was, and sent by sea from Batavia to Cheribon; and this idea caused me to apply for information to the controller of customs, when I landed at Cheribon. This official, Heer A. K. J. Kaffer, explained to me that the landing of Java tea at his port of residence had attracted his attention, and that he had instituted successful inquiries regarding the circumstance. I learnt from Heer Kaffer that at that time there were six tea factories in Cheribon, the chief place in the Residency of that name, where Java tea of inferior quality was so manipulated that it was converted into a superior kind of China tea, and the difference in the selling prices of the two kinds of tea forms the cause of the extent attained by this industry.

An import duty of 20 cents per kilo (or about 10 cents (of a guilder), is levied on tea from China; whilst Java tea is duty free from any port of Netherlands-India to another.

From the nature of the case the Cheribon tea alteration at Cheribon is in the hands of the Chinese.

Large quantities of the prepared produce of the tea plantations in the West Praeger and Buitenzorg districts, of a quality unsaleable in the European market, finds eager buyers in the Chinamen of Cheribon, who transport it to that place via Tandjong-Priok. This product undergoes a manipulation at Cheribon which improves it to such an extent that none but good tea connoisseurs can distinguish it from the inferior sorts of real China tea.

Heer Kaffer states that the native population forms the largest number of consumers of this worked-up tea, the packing of which is such that when it leaves Cheribon it is impossible to distinguish it from that which contains the tea which comes from China. For the packing there is an establishment at Cheribon where the chests are made, and another for the preparation of the loaden lining, as well as a printing press for the labels for the separate small packages; the paper in which they are put up comes from China, as well as the gilt thread for tying them. Each package holds about the tenth of a katti. The chests are packed in bamboo baskets, which contain either one chest of 20 kattis, 4 chests of 5 kattis, or 8 chests of 2½ kattis each. The last mentioned finds the readiest sale. According to our above-mentioned informant the small chests holding 2½ kattis are sold at Cheribon for a guilder a piece wholesale, and the larger packages at the same rate per katti. For superior qualities the price is naturally higher, as the Chinese, by their mode of working, obtain tea of various qualities. The profits of the China tea-alteration industry are so great that the Chinamen in the Residency of Tegal have commenced competition. In a short time already four factories have been established in Tegal for the conversion of Java tea into so-called China tea. In September last when I was on board of the "Van Goens" in Tegal roads, I witnessed the landing of about sixty large packages of tea from Batavia landed at Tegal in prams. There is no saying to what extent this industry will reach in the Eastern residencies, especially when the natives shall be induced by advances of money from the Chinese to cultivate tea for them. That the large sale of this Java-China tea, as I may call it, amongst the population has an injurious effect on the public revenue is evident. The records of the Cheribon custom house already establish the fact that the import of China tea has been of late yearly diminishing. There is nothing fraudulent in the circumstance of improving the quality of the tea by a peculiar method of preparation or re-preparation; the fraud consists in the sale of the improved article as the produce of China as testified by the tickets and labels on the chests and packages. The translation of these (from the Chinese) which follows hereafter, is due to the kindness of the Heer W. P. Groeneveldt. On the front and back of the chests the writing is the same, the name of the seller Chintubun is inscribed in large letters, and in smaller characters stands "fine tea from the Thai mountains." On the top of the chest the words "fine tea, Kimhoug sort"—being the name given to the sort of tea. On each small packet stands the same in black letters and above this inscription is printed in red letters "selected first quality" with the mark of

the seller. In each chest on the tea lead is placed a red paper with a printed notice in black letters of which the following is a translation:—

"The undersigned, Ang Chin Chng, goes himself every year to the renowned Bu-hic mountains* in the early spring for the purpose of selecting fine kinds of tea pure and sweet in taste and smell; this tea is immediately packed to be sold far and near.

"Now there are shameless fellows (schaantlooz kerels), who actuated by an unwarrantable thirst for gain have counterfeited my marks, and have thus deceived the public.

"I therefore request my honored customers to be pleased to note that I have, to provide against this, had a red mark printed obliquely across each packet—this is the true packing—and it is found as described, there can be no mistake. Spring of 1886.

"Respectful notification by the seller."

The Chinose of Cheribon attribute, what to their taste is, the inferiority of the Java tea first to its preparation by means of machinery, and secondly to the absence of perfume, because the flowers which serve in China are not made use of. If they could obtain the fresh tea leaves, they would be in a position to make a still closer approach to the real China tea, than they can do by working up already prepared tea. Therefore some of them have entered into contracts with certain tea plantations in the Sumedang districts for the supply of fresh leaf or leaves partially prepared to be delivered at Cheribon. Lately the following circumstance was mentioned to me:—

As is well-known the tea bush has to be pruned, when the branches become too long, the prunings serve to make manure, and locally have no other value. A Chinaman of Tegal, however, made a bid to a tea planter of the Buitenzorg district of 2½ cents for the prunings of each tree with the object of transporting the leaves to Tegal. I do not know what preparation such tea leaves were to undergo at Cheribon or Tegal.

The Heer Kaffer describes the process to which the prepared tea is subjected as follows:—

As soon as the tea arrives and is unpacked a portion of it is mixed with flowers, after which the mixture is covered over with blankets or gunny bags for one night in such a way as to exclude the outer air. The proportion of flowers to the tea is from 5 to 10 litres of flowers to 1 hectolitre of tea. These quantities mixed together are just sufficient to fill a drying basket. The day after the flowers have been mixed with the tea the whole is dried together. The drying basket in which the further preparation is effected, is of interwoven bamboo, and has the form of two truncated cones, the smaller sections being joined together, so that the upper portion is of the same size as the base, gradually narrowing from top and bottom to the middle. The basket is divided into two equal portions by a partition forming a sieve. The upper portion is of sufficient capacity to hold the mixture above-mentioned, whilst the lower portion remains empty. The whole is placed over a charcoal fire made on the floor, and covered with a thick layer of ashes, so that only a moderate warmth radiates, sufficient however to dry the tea thoroughly. The more slowly the drying is effected, the hotter the quality of the produce obtained. This drying lasts from 3 to 5 hours. Simultaneously with the drying of the mixture of tea and flowers in this manner, a similar process is carried on with another portion of the same lot of tea, that has not been mixed with flowers, and with which the upper divisions of three drying baskets of similar size are filled. On the completion of the drying process which occupies the same time for all four portions, the baskets are taken off the fire, and the contents of the three last mentioned are intimately mixed with those of the first, from which last the flowers have been, for the most part, carefully removed. The tea is then ready for packing. The flowers used in this mode of preparation, are the

* The so-called Boher mountains in the Province of Hokkien (China).

same as those similarly employed in China. Those principally employed are from the *Jasminum sambac*, Ait, the well-known *melati*. (Called the Mugerine in Ceylon or double jessamine.—*Note by Translator*.) They are purchased while they are buds and used when the flowers open. They are spread out on bamboo sifters and sprinkled with cold water until they open. They are on no account allowed to be floated in cold water to cause the opening of the buds.

In the next place come the small yellow blossoms of the *Aglaja odorata*, Lowe, *A. Meliacea*, which is known at Batavia by the Malay and Indo-European population as the Patchar China, and by the Chinese as the Kembang Chulan; and at Buitenzorg the latter term is used by the native population. A Javanese of Bagelen stated that this plant was called in that district Patchar Prentil.

The dried *Aglaja* flowers resembling little seeds are imported by the Chinese from China for use when the fresh flowers are not to be had for perfuming tea, but they are frequently musty, and of weak perfume.

In the third place, the large white sweet-scented flowers of the *Gardenia pictorum* Hsskl, are made use of: this is one of the plants generally known here as the Katcha-piring.

Considering that the same flowers are used in China for perfuming tea, and that they do not communicate any substance prejudicial to health to the tea, the tea-alteration as practised at Cherihon does not operate mischievously in a hygienic point of view, so much as with the revenuo.

However, I consider it of importance that the circumstance of the existence of the practice should be known to a wider circle; and I am therefore thankful to the Directors of the *Teymania* for the insertion of this communication in their periodical.

Batavia, November 20th.

HOW TO ADD TO OUR FUEL SUPPLY.

Mr. Edelmann, a Pole by birth, who has been on a visit to Ceylon, has, says the local "Times," made a discovery for greatly adding to the fuel supply of the world. The starting point in connection with his scheme is that there exists near the surface of the earth a large quantity of what may be termed inferior coal, which is commonly called lignite. Lignite however, has not the chemical properties that bituminous and anthracite coal possess, and so will not burn, and Mr. Edelmann has applied himself to the discovery of the chemical properties necessary to enable it to burn. He now claims to possess the secret and has patented his discovery in all the principal countries of the world. His botanical knowledge has been of great assistance to him, for without it his idea would probably have died at its inception. A long time ago he noticed that all coal was formed largely of vegetable matter and that the soil has a magnetic power which draws in heat. That was one fundamental discovery on which the later results hinged. Having come to this conclusion, Mr. Edelmann spent many years in travelling over the world in search of plants that contained the elements of heat, gas, and fire in the greatest degree. These investigations he conducted principally in the forests of Russia, Germany, and other European countries, and also in Africa and South America. When he had satisfied himself as to the plants which would best serve his purpose, he made a study of them until able to extract from them the qualities he desired; but as soon as he had done so and placed them together the one destroyed the other and they disappeared. He therefore had next to find out what would prevent this disastrous evaporation of the ingredients which he had got from his plants with such toil, and this inquiry was the hardest part of his work. It took him in all eight years, but now he claims to have succeeded, and he is having works erected in Southern France, where he means to show the world the first results of his labours, and then having done that, he will sell his patents to the different countries in which they have been taken out. The process by which Mr.

Edelmann says he will make this lignite into coal is as follows:—The lignite and certain chemical bodies which have first been reduced to a powdered condition in order to admit of their perfect commingling are placed in moulds and subjected to great pressure by machinery expressly constructed for the purpose, and from which the mass comes in shape, of what are termed, for want of a better name 'brickets.' These 'brickets' can be made of any size or shape—large for furnaces and small for stoves. The immense pressure brought to bear on them makes them harder than coal. The lignite coal is smokeless and there is only one per cent of ash. The heat produced by it is greater than with ordinary coal. Lignite is found near the surface of the earth, and so the cost of mining is reduced greatly, while at the same time the supply is practically inexhaustible. The chemical bodies used are also in expensive, so that the new coal can be manufactured and sold at a much cheaper rate than bituminous or anthracite coal. Mr. Edelmann, as stated above, intends beginning work in the South of France. He knows the discovery is all right and he has proved it before a commission in America. He now wants to shew the world at large that he is correct, and then he will make the most he can out of his discovery. Mr. Edelmann has acquired a large tract of ground in Texas where he thought of putting up some of this machinery, but he has now given up that idea and intends to make a beginning with his new discovery in France. The works he is having put are on an elaborate and expensive scale and will not be finished till July.

THE RIVALRY OF TEA GROWERS.

The controversy as to the respective merits of tea from various districts has begun. This letter of Mr. Hicks in praise of the superiority of Ceylon tea over Indian has, as we thought, led to further correspondence on this subject. "A Tea Planter of Thirty Years' Standing" now writes advocating the claim of tea grown in the Himalayas. "It only remains for tea planters in Assam, Darjeeling, the Wynad, and elsewhere to enter the lists in favour of the teas grown in their respective districts, and the tea drinkers will find themselves in a hopeless state of confusion. It will no longer be a question of Indian and Ceylon tea v. China, but each district, and possibly each garden, in India and Ceylon will have its own advocate in the Press. If this rivalry develops we shall see each packet tea company printed on its labels an analysis of the tea it sells and of the soil upon which it is grown, and particulars of the same sort will be expected in the sale room, a state of things which the brokers and dealers of Mincing Lane will not enjoy. Future advertisements will be in this style: 'Buy Jones's Ceylon; beats all other tea; no injury to health; on astringency;' or 'Try Giles's Kumaon; beats certain for delicate flavour; grown on high ground; light; exhilarating;' or 'If you wish to grow fat ask for Puffer's low country tea; both nourishing and refreshing; full of body; contains both a maximum of theine and a maximum of flavour.' This will be going into detail with a vengeance, and the poor consumer, fearful of losing his reason, will take to coffee or cocoa in despair."

The advocate of Himalayan tea says, in the course of a long letter:—"As I have had more than thirty years' experience in the growing and manufacture of tea, and have also visited all the best known tea-growing regions, namely, India, China, Japan, Ceylon, and Java, and made myself conversant with the various methods of sowing or manufacturing the leaf in vogue in these countries, I venture to thoroughly endorse all what Mr. Hicks has so ably set forth in his letter, with this exception, that there are certain districts in India that grow as fine, if not even a finer, quality of tea than any grown in Ceylon, namely, the tea estates of the Himalayas. In China and Japan, the China variety of shrub is alone grown. In India there are three varieties of plant cultivated—the Indigenous Assam, the hybrid (a cross between the Indigenous

and the China plant), and the pure China plant and in Ceylon, both the Hybrid and China variety. Both in India and Ceylon the Hybrid is the favourite, as giving both a large crop and a tea best suited to the present requirements of the English market—that is, a strong, thick, astringent liquor. Both the Indigenous and Hybrid varieties require a hot, humid climate; but the China plant prefers a colder and less tropical atmosphere, and is, therefore, cultivated in the Himalayan inner ranges, and the Indigenous and Hybrid at the foot of these mountains, in the low, hot humid valleys. Taken roughly, the yields per acre of the three varieties are as follows:—Indigenous, 1,200 lb; Hybrid, 800 lb; China, 250 lb. From this it will be seen why the Hybrid is the favourite with tea planters; the yield is so much larger than from the China shrub, and the tea not so coarse and astringent as that from the Indigenous although not nearly so delicate as that from the China plant. For many years past the managers of tea estates have been urged by their agents and brokers to turn out thick, dark-liquoring teas, as such alone command the market. This command has been obeyed at all gardens not growing the China variety, which will never produce these thick dark-liquoring teas, as it is deficient in tannin, but abounds in theine, owing to its nature, soil, and climate, which gives it its fine, delicate flavour, and light, limpid liquor. The demand for thick, dark liquoring teas is not far to seek, the thicker more astringent, and darker liquoring the tea is, the less quantity of it will be required for blending with cheap, low grade China teas, to give them point and flavour, and thus ensure a larger profit to the tea merchant. The fine, delicate-flavoured, but light-liquoring tea produced from the China plant is useless for blending purposes, as it is pronounced 'thin and poor' by the trade. At what cost has the public been educated by the tea trade to use nothing but thick, dark-liquoring teas? The public is assured that such teas are hotter value, as they go much further, taking two or three waters and still yielding a good liquor, whereas light liquoring tea will not stand more than one water. This is quite true. But what is this deception that is so economical? A decoction of tannin, from which the refreshing and invigorating properties of theine had been eliminated, in the process of fermentation, in order to bring out the tannin, to give the much desired dark, thick liquor, at the expense of losing the volatile oils and theine by evaporation. Medical men are now alive to the injury done to health by these thick dark-liquoring teas, and are condemning their use. What Mr. Hicks claims for Ceylon teas, grown at high elevations, is still more notable in Indian teas grown in the Himalayas, where the climate is neither so hot nor humid as in Ceylon, and, therefore, growth less rank. In Ceylon the tea season is nearly all the year round, whereas in the Himalayas it is barely six months—from the middle of April to the middle of September, when frost and snow set in. These delicious teas have been virtually driven out of the market, being pronounced by brokers as poor and thin, although delicate and flavoury, owing to the low price they fetch, combined with small yield. Whereas the large yield and hotter price for the thick dark liquoring teas from the Hybrid plant, grown in the hot, humid low-lying valleys, command the English market, and assure their prosperity. Should the public take back into favour the delicate fine teas grown from the China stock at high elevations, and thus by its demand, improve its present unremunerative price, there is a great opening for its development in the thousands of acres of magnificent lands in the Himalayas to be had on easy terms, with abundance of cheap local labour. Mr. Fortano, after visiting China on behalf of the Indian Government, when introducing tea culture into India, selected Knaon, N.W.P., as being identical in soil and climate to the Bohea Mountains, the finest tea district in China.

Now all this may be true, but it is a matter for exports rather than the public.—*H. & C. Mail.*

NOTES ON PRODUCE AND FINANCE.

AN OLD STORY RE-TOLD.—"Nor, in the matter of tea have the public at the beginning of the year 1892 much cause for complaint. Tea is wonderfully cheap, and, on the whole, remarkably good. It is no longer the practice to sell as tea shonnable compounds of sloe-leaves and hirtch-broom, while the astonishing development of the tea industry in India and Ceylon has filled our markets with stimulating and fragrant products, the excellence of which, while doing no injury to the superior kind of Chinese teas, has relieved the community from the disagreeable risk of swallowing decoctions made from the sweepings of Chinese warehouses, containing a minimum of tea and a maximum of downright dirt." The above is an extract from an article on adulteration in the *Daily Telegraph*. As far back as 1879 we were alone amongst newspapers in pointing out that India tea was never adulterated, and that was one of many strong reasons why consumers should purchase it. (Ceylon had not then produced much tea.) It is gratifying to find that the Press and the people are now recognizing the purity of India tea.

A BRILLIANT SUGGESTION.—A correspondent of the *Grocer*, who has read the report of the Ceylon Tea Plantations Company, writes as follows, and modestly suggests the extinction of the dealer and the planter:—"I was particularly impressed with the dividends paid, which have been at the rate of 15 per cent per annum, even with the expenses usually attending a public company. Surely this is sufficient profit to tempt business men to form a company to sell direct to the retail trade, and thus save the wholesale dealer's profit, which, with travellers' and other expenses, must add a further charge of 10 to 20 per cent, or hotter still, let leading retailers combine, and be their own planters." One large tea dealer is his own planter. It would help the correspondent from whose letter we quote to a solution of the problem which vexes his soul, if he could induce this large dealer to tell him whether he finds that portion of his business lucrative.

IN PRAISE OF DARJEELING TEA.—A correspondent, who signs himself 'Darjeeling,' says:—"In the *Daily Telegraph* of Jan. 6th 'A City Man' affirms, 'China tea of the first quality is of a very delicate flavour and very fine drinking.' This remark, I submit, applies with equal force to the delicate teas produced in Darjeeling and Kangra, in the hill districts of India. These teas are some of the finest in the world, and if Russia takes the best of the China teas, England should take the delicate teas produced in the Himalayas at Darjeeling and Kangra, where Englishmen and English capital are producing what is A 1."

PLANTING IN THE WYNAAD.—The outlook for tea in this district is considered remarkably good. Tea has been planted in small areas in anticipation of the establishment of Central factories, and a recent report upon tea gathered from two-year-old bushes on the Richmond estate, the property of Mr. Punnett, is most favourable. The *Madras Times*, apropos of this, says:—"The news published from Wynaad is excellent, and it seems as if the Wynaad tea planter will be able before ere long to snap his fingers at his brethren from Californiata Ceylon. With Mr. Roscoe Allen's grand trunk road close on completion, all fears should be removed about the preparation of the leaf when once plucked, if after a twenty miles' jaunt such an excellent report can be obtained. Mr. Punnett is to be most cordially congratulated on the success of his experiment. We can see nothing now to prevent companies devoting their large acreages of unproductive land to the cultivation of the tea bush, and under planters of practical experience, profits and good ones, should figure in their balance-sheets."

THE CHINA TEA TRADE.—Colonel Vincent, in the *Daily Graphic*, has stated that "Because the import of China tea into England has fallen off so much during the last ten or fifteen years, the tea industry in China is threatened with extinction." "A Tea-Broker" thereupon writes as follows:—"I would point out that the export by sea and land from all China reaches the large total of over 200,000,000—about as much as

she ever exported. Large quantities go to Russia, England, the United States and Canada, Australia and New Zealand; and smaller quantities to South America, South Africa, and the Continent of Europe; while even India takes 3,000,000 this year, being about the usual quantity. The falling off in the revenue in Foochow may be accounted for by the considerable increase at Kinkiang and Haokow. The reduction of the export duty might prove a temporary expedient for the importing of China tea into England; but it is better tea from China that we require. The small export duty would have little prejudicial effect in their competition with either India or Ceylon. I am of opinion that the present China tea gardens are exhausted. The tea shrubs have become rank, and nothing but replanting will bring about the consumption of China tea to any great extent in England."

TEA IN UPPER SIAM.—In his paper on the Laos States of Upper Siam, read before the Society of Arts on Tuesday, Mr. Ernest Satow, in describing his journey round the highest mountain in the neighbourhood, Doi Suthep, said he met with some old tea plantations, where the plant reached from 12ft. to 15ft. in height. The leaf was longer and more pointed than that of the Japanese tea plant, and it was probably the same variety as that which furnished the Asam tea. The Laos did not drink the infusion, but prepared the leaf for chewing by burying the leaf in pots and salting it. No exterior trade was done with the tea, which was issued for domestic consumption only.

LAST WEEK'S TEA SALES.—The *Produce Markets Review* says:—The Indian tea market has been severely tested by the heavy supply, amounting to upwards of 48,000 packages, or about 4,500,000 lb. It was expected that with this heavy supply, coupled with the probability of a still larger quantity to be offered next week, prices would be forced down to a lower level, but this has not been the case as the market not only opened firmly, but closed so, for most descriptions. If importers, however, continue to force their teas on the market regardless of the ability of the trade to take them, the inevitable result will be that they must submit to a lower level of prices. The stock in the bonded warehouses under ordinary circumstances would certainly indicate a decline in values, but Indian tea is so moderate in price and the consumption so largely increasing, as evidenced by the deliveries of the past three months, which amounted to about 40,000,000 lb., that any further material decline will only be brought about by excessive supplies. At this period last year Pekoe Souchong, and in fact, all the lower grades, were from 2d to 3d higher than at present, which was due to a speculative demand, but at no period of last season were prices below those now ruling. With a continued improving demand, therefore, there is no reason why prices should fall unless supplies are indiscriminately pressed forward, in which case the decline will only be temporary. The opening sales of Ceylon teas have been smaller than was anticipated and prices up to the present are somewhat higher than the closing rates of 1891. This result was, however, mainly due to the large buying of some of the packet companies who seem to anticipate still higher rates, a belief evidently not participated in by the dealers in general, who abstained from buying in a perfectly marked manner. The sales advertised for next week are quite up to the average quantity, and no scarcity of tea need be anticipated at present. The quality of the week's sales has shown some improvement but still leaves much to be desired.

COFFEE IN 1891.—The course of the coffee market last year may be summarised thus. It steadily advanced until the middle of March, when the highest prices of the year were reached, middling plantation Ceylon touching 110s. Importers, tempted by the high prices ruling then, offered rather freely, and value gave way somewhat, but the demand being good, especially for the finer grades, the decline was only a gradual one. At the turn of the year the upward movement was again resumed, the supplies being light and the trade demand good, but at the beginning of September the heavy receipts in Brazil and free offer-

ings on cost and freight terms caused a considerable relapse, middling plantation Ceylon declining to 90s. A rather better demand from the trade then caused a steadier tone, and the revolution in Brazil gave an additional fillip to the market, the fear that shipments might be delayed causing holders to raise their quotations. For a time the advance was not readily paid, but with unusually light supplies exporters and home buyers were soon compelled to pay the prices demanded, and the market has continued to advance to the close, 103s 6d being now the ruling price for middling plantation Ceylon. The terminal market has been dull throughout, and at no time can it be said to have displayed any real animation. Santos has been almost entirely neglected. During the earlier part of the year prices improved somewhat, Rio standing at 82s 6d in May, but from this time the receipts at Rio commenced to increase, and as these grew the quotations dropped away until, at the beginning of October, 53s was the current value of Rio, and 56s for Santos. At this date the heavy crop movement began to fall off, and with less pressure on the part of importers to sell on c. and f. terms, prices gradually recovered. The stocks of Europe, according to Messrs. Duuring and Zoon's last returns, were 38,550 tons, against 62,750 tons at the end of last year. The visible supply amounted to 140,951 tons, against 143,491 tons last year. The landings in London during the year have been 34,157 tons, against 41,172 tons last year. The quantity taken for home consumption was 14,295 tons, against 13,642 tons, and for export 21,556 tons, against 30,932 tons.—*H. and C. Mail*, Jan. 15th.

A NEW TEA CHEST.

Under the title of the Aeme Tea Chest Syndicate, a company has been formed and registered in Scotland with a capital of £8,000, in 1,100 ordinary and 500 deferred shares of £5 each, to acquire certain patent rights, held by Henry James Stewart Brown, Egremont, Cambuslang, relative to the manufacture of chests; to adopt and carry out an agreement entered into with Mr. Brown; and to carry on the business of making and manufacturing, and to sell, hire, let, and deal in metal or other chests or boxes for holding or carrying tea or other commodities, or chests or boxes of all kinds. That regulations in Table A of the Companies Act, with slight modification, to be the articles of association. The first directors are Arthur Machan, Anderson Iron Works, Craohton-hill Glasgow; John Binnie, Star Engineering Works, Moncur Street, Glasgow; William Cook, 74, Galbraith Street, Glasgow; James Couper, jun. (of James Couper and Sons), City Glass Works; Glasgow; and William Porteous, Anderston Galvanising Works, Glasgow. Mr. Peter S. Brown, late manager of the Iron and Steel Fencing and Buildings Company, Glasgow, is to be manager.—*H. and C. Mail*, Jan. 15th.

INDIAN TEA.

TO THE EDITOR OF THE "MORNING POST."

SIR.—The rapid growth of the Indian and Ceylon tea trades, not only in this, but in Russia and other tea drinking countries, appears to be causing the old traders in China teas some trouble, the rapid decline in consumption of China tea, especially in this country, obliging them to employ various methods, by advertisement and otherwise, to endeavour to prevent the striking of the teas of British competitive growth, which are daily becoming more appreciated by the public. It is unfortunately true that much tea is being sold now under the titles of Ceylon and Indian that contain only a small percentage of either of the above being composed largely of ordinary China tea, to the detriment of the former; and several prosecutions have been successfully undertaken to stop this practice, by parties interested in seeing that the public get the genuine article. In the *Ceylon Observer*, just to hand, an article appears in which these China traders are charged with issuing

advertisements with intent unjustly to damage the Ceylon tea in the public estimation. It asserts "that it is only natural that China tea dealers should desire to preserve the trade from which they have so long profited, and had they contented themselves with exalting the merits of their black leaf China teas, their advertisements would have been allowed to pass unnoticed; but the virulent libels they contain on the superior teas of India and Ceylon, are, it believes, knowingly false. One Glasgow firm at least, who describe themselves as ten tasters of 25 years' experience, must know that medium Ceylon and Indian teas now selling at moderate prices are equal to the very finest high-priced teas which China produced in her best days;" also the statement "that India and Ceylon teas yield four to five times as much tannin as China teas" is absolutely untrue.

"There is, in the Indian and Ceylon teas, just a sufficiently larger percentage of tannin to constitute their superiority to those of China. If China tea is treated so that all the tannin is exhausted from it, the brew will be either a pleasant nor a wholesome beverage, and no person who knows how to infuse it properly will leave boiling water more than five or six minutes over the leaves. The proportion of tannin in such an infusion of the strongest Ceylon or Indian teas is not injurious but beneficial, notwithstanding the opinion of Sir Andrew Clark to the contrary. The public know their own interests and the beneficial effect of tea, properly made, too well to be affected by the utterances of medical men or the advertisements of dealers of the class above alluded to; and in spite of medical and mercantile partisans, India, and especially Ceylon, teas will increase in favour and in consumption, to the benefit even more of consumers than producers, although, we trust, with ever a fair profit to the latter." There is an amount of truth in the above article, as will be seen from my following remarks.

China tea naturally possesses less tannin than either Indian or Ceylon tea, and if the Chinese had been able to maintain the juicy, fine pekoe flavoured teas they made 20 years ago, instead of year by year allowing the quality (with the exception of a few finest crops) to decline, the public would still support them; but the bulk of the crops the last 10 years has consisted very largely of thin lignoring and tarry teas, of the common to good common grades, and the few really fine parcels have of late commanded prices that few retail dealers could afford to pay. Meantime, India and Ceylon have steadily produced year by year larger quantities of an article containing much more flavour and point, and one which can be sold here at prices giving in proportion much better value. However, Indian teas cannot be placed (as the writer of the article referred to would have) in the same comparison with the good old China Ningchows, as Ceylon teas can. At the present time Ceylon pekoes selling at from 11½d to 1s 2d per pound in the market, are generally equal to the finest old China teas which, 15 or 20 years ago, realised 2s 6d to 3s per pound, and by far superior to the best of the same class that arrive now, and command at the opening of season on the average about 1s 6d to 1s 8d, and a few chops of exceptionally fine, 1s 10d to 2s per pound.

The rapid increase in the deliveries of Ceylon teas month by month, and the corresponding decrease in the demand for China teas, sufficiently prove this. That Indian teas have now more virtue in them than China teas is true, but the Indian are mostly more stringent and pungent than Ceylon teas, and not so suitable for drinking alone, these from a few districts excepted (namely, the Darjeeling, Doonars, and Kangraes), which makes them more suitable for blending purposes. The liquors of China tea, if brewed unduly long, become bitter and unpleasant, and with other growths the same result. Consumers, when buying strong Indian or Ceylon teas, should learn that these are much more juicy than China teas, therefore less quantity need be used, and infused for at most five minutes, when it will be found they throw a stronger liquor than the same amount of China tea would in double or treble the time. The references made in the article to the expressions of various doctors on different teas,

and to the one doctor especially, who warns the public against Indian teas, is a just rebuke; they can no more stop the consumption of any favourite drink, such as tea, than they can prevent the use of tobacco, either of which if taken improperly, or in too great quantities, are injurious, and to some systems more than to others.

Sir Andrew Clark, speaking at the London Hospital, on October 13th last, stated "that tea to be useful should be first of all China tea, the Indian tea having become so powerful in its effects upon the nervous system, that those who take it actually get into a state of tea intoxication, &c. "If," he had, "you want to have tea which will not injure, and which will refresh, get black China tea putting in the right measure," &c. With due regard to such an authority as Sir Andrew Clark, who has every right to prefer China to India tea, he should not go so far without good reason to damage an important article of British trade in the public estimation. He hits the very nail on the head when he says, referring to China tea, "if the right quantity be put in the pot." Here is the pith of the matter, if people buy strong Indian tea and put the same quantity into the pot as they do of China tea the natural consequence is that the liquor draws too strong; but if the consumers understand how to brew Indian tea—viz., less quantity and less time to draw, it is just as wholesome a beverage as China or Ceylon tea. If doctors instead of condemning an article like this would learn the different properties of the various growths, and then advise their patients how to make and not abuse it by too constant use they would be doing them much kindness. It is a common thing to go into a drawing-room of an afternoon and be asked to have a cup of tea, which probably has been standing for, perhaps, half an hour or more! That this should result in causing indigestion, or as Sir Andrew Clark classes it, tea intoxication," is not to be wondered at.—Yours, &c.,

MINING-LANE.

Dec. 23.

INDIAN IRRIGATION.

BY ALFRED DEAKIN, M.P. (VICTORIA.)

[In the *Sydney Morning Herald* has appeared the final paper of a most painstaking and able series, in which the late Chief Secretary of Victoria, a very promising Australian-born statesman describes, from personal observation and extensive reading, the irrigation works of India and Ceylon in their bearing on irrigation in his own great thirsty land. A few extracts from this summing up will be interesting to our readers.—ED. T. A.]

Much might be said on other aspects of Indian affairs, but here the series of papers relating to irrigation attain their conclusion. A large volume might be written upon the practical, scientific and commercial phases of the question for those sufficiently interested to follow them into all their details. What has been attempted in these articles has been to offer a sketch, hasty and rude, which might be of some service in any consideration of the Australian future of water supply. To illustrate the size and character of the Indian works, and their dependent interests, blue books have been freely drawn upon, and personal investigations have been employed to interpret them, with the result that the information collected and collated is probably new to many in India, and to all outside it, except, perhaps, a few retired officers of its departments.

The whole makes no pretension to be comprehensive, but only to be faithful so far as it goes. Even in regard to irrigation its scope is limited by the writer's want of technical knowledge, and by the fact—which has affected both style and substance, that his criticisms have made their appearance in the columns of the daily and weekly press of the capitals of three colonies. On the general history, finance, position and prospects of the great Government schemes they claim to be accurate and fairly complete. No publication is known to the writer having the same end in

view. His obligations to existing literature have been freely acknowledged in the course of the papers, and it would afford him unalloyed satisfaction if some better qualified person would devote to the irrigation of India the prolonged investigation and expert exposition which it deserves. The debt of obligation which the country is under to the British Government, and the British Government to its engineers, will otherwise never be known or estimated as it probably will never be discharged.

In India irrigation of some kind, probably in the first instance from inundation canals, antedates history, though it was not until the thirteenth and fourteenth centuries that any works pointing to the perennial canals of today appear to have been attempted. There are remains of large diomed storages in all parts, and some still in operation are of great age, but the watering from these has never been relatively extensive. The primitive rain-filled tank, or little well, remains the chief sources of native supply outside the domain of the Government schemes. Millions of acres have been, and are, irrigated annually from them by the simplest means. It is to these, and not to the Mulal canals, or the tanks built by Muhammadan monarchs, that the people have trusted for centuries. Almost every field had its own separate supply, the task of securing and utilising it forming the chief concern of the ryot, and the title to its possession being more important because necessarily implying that to the land which it made fruitful. The cattle required to draw water from the deeper wells form on this account a chief element of the farmer's wealth, and their capital value has assisted in certain districts to make a distinction between the proprietor and his labourers. The whole agricultural system, and in some degree the social system, of parts of India have been greatly modified by the practice of irrigation, but in ways which have nothing to teach us. The solitary inference to be drawn from a glance at the Hindu experience is that similar results are certain to follow in Australia, where new principles of ownership and fresh legislation recognising a property in water is inevitable. It would be well if they were introduced at once, before more vested interests are created.

How widely the position of the farmer under the Victorian Irrigation Act varies from that of the Indian ryot under an irrigation canal should scarcely need further exposition. The ryot has no responsibility except to pay for the water when he gets it, and even then may obtain a partial or complete remission if his crop fail. This may seem an ideal condition to the resident in the Gonburn Valley, but it must be remembered that this immunity from risk is part of a system, and is purchased by serious disqualifications of another kind. This Victorian farmer within a trust area is responsible, not only for the water he may purchase, but for his proportion of the difference between the sum obtained from sales and the amount necessary to pay 4½ per cent. interest upon the capital cost of his scheme, and of the national work, if any, which feeds it, after providing for working expenses. What he gets in return for this is the power of voting for or against a scheme in the first instance, and of shaping it afterwards to meet his view of present necessities with the right of managing it economically and so as to insure justice for himself and those who live near him. Finally, if he pays his sinking fund long enough, the obligation upon his land for interest will be entirely extinguished, and the whole scheme will become the property of his children who will be liable only for levies to meet its working expenses. The means of criticism which he enjoys attaches to him, it is true, not as a trust member, but as a citizen of a free community. Yet he would not have the power to make his criticism effective, as the mere unit of one constituency for each branch of the Legislature, in anything like the degree that he enjoys as the constituent of a small body in which his personal influence can be directly exercised. Local control can scarcely fail to be more effective, as well as cheaper, than control from a distant capital by political agencies.

The irrigation expenditure of the British Govern-

ment may be viewed in several ways. Thus, regarding works which are almost wholly new, the figures would run:—

	Expenditure.	Acres irrigated annually.
Ajmere ...	£160,000	38,000
Bombay ...	2,500,000	85,000
Sind ...	1,180,000	150,000
Bengal ...	6,000,000	550,000
North-west ...	8,000,000	2,000,000
Madras ...	5,300,000	2,400,000
Punjab ...	6,500,000	3,000,000

The fact that native works have been more largely utilised in Madras than elsewhere partly explains the relative cheapness of its schemes. Roughly it may be concluded that British canals have cost £4 per acre irrigated and pay 3½ per cent. on the outlay. Adding native canals utilised in Government schemes the table would be increased by—Burmah, 200,000; Sind, an extra 1,000,000; and Madras another 2,500,000, making about 13,000,000. for £33,000,000, yielding 4 per cent. net revenue. In the course of a few years the totals will have risen to about £35,000,000 outlay for 15,000,000. watered, reckoning twice cropped land twice, so that in reality the actual surface cultivated is considerably less. To this total has to be added the immense extent of country everywhere, but especially in the north-west and in Madras, supplied from well, and tanks by the Hindus themselves, and also the totals of the independent states, including Government and private schemes. There is no absolutely trustworthy record of these, but it is safe to say that they more than double the land irrigated from the canals of the British Government. There are therefore over 50,000,000. watered every year within the Empire, with a constant tendency to increase the area. Nowadays this increase is limited by the fact that almost all the accessible supplies have been utilised, and, as in the Punjab, large schemes are required to command new territory. Neither in Bombay nor in Bengal does irrigation pay the State, but major works pay 5 per cent. in the Punjab and in the north-west, 7 per cent. in Madras and 12 per cent. in Sind. It pays the Hindu everywhere, for without it some millions could not live at all, and some millions would be decimated by famine every few years. Reckoning its influence upon the railways, commerce and good government of the country, its value is simply incalculable.

The State in India means the Government in a deeper sense than in Australia, for in that country the citizens are unable to mould the Government to their wishes, having practically no political opinions, and no political privileges whatever. Instead of projects for the watering of a special area originating with the farmers, as in Victoria, and being subject to their specific approval, the Indian ryot, although in most cases he bears the same responsibility for interest upon the capital expended in providing him with an artificial water supply, is never consulted in any way or at any stage in the construction. Government initiates, designs and executes the work, offering him the water if he likes to take it, and relying only upon his self-interest to induce him to become a purchaser. In the Panjab a system of compulsory labor prevails, and in Ceylon the sanction of the natives concerned is required before Government advances are made, but in each case this has regard to minor works, in which the State is little more than a sleeping partner. Upon all "major" schemes the Government acts upon its own motion, at its own responsibility, and acknowledges no title in those who use the water to criticise its proposals. In an equally pre-emptory way it ignores riparian rights, or makes but small compensation for actual injury done or land taken; not that this involves injustice, but because the tenure of land is less absolute, and the property affected far less valuable than in Australia. The advantages of a despotic rule are exhibited in such cases as these, where the officers of the department are perfectly free to choose the best scheme possible, and to execute it without regard to the individual wishes of interests of their

constituents. In the colonies these would be forced upon their attention at every step, and they would require to pay dearly for any encroachment, or imaginary encroachment upon them.

Except in Ceylon the great Irrigation works of India are constructed with borrowed money, raised in London, and charged to the works at from 3½ to 4 per cent. The price need not be wondered at, seeing that the guarantee of the British Government is behind the debentures.* Though this of itself would suffice, there are the further facts that the money is spent in a populous empire, with an enormous revenue, and that the works as a whole are very remunerative. In Madras, the North-west, the Punjab and Sind they yield handsome profits; in Bombay they are likely to pay for themselves, and in Bengal they are, after all, the cheapest and best means of fighting famine, and saving the public treasury from ruinous drafts in bad seasons. On the merits of the investment, therefore, the stock would be entitled to rank high, apart from its guarantee. Before the colonies can hope to see their irrigation proposals regarded in the same light they must be able to satisfy the capitalists of the mother country that the outlay is reproductive, for quite content with the credit of the Government the Briton has never really considered either India or Victorian expenditure under this head. Except the directors of the Scotch companies, which have done well in Colorado and other of the American States, the moored men of Great Britain know nothing of irrigation ventures. The Madras and Orissa companies, if not forgotten, would certainly have not encouraged a favorable view, even in India. Those who lend upon colonial securities are entirely unacquainted with them, and are likely to regard State loans which are employed to benefit private lands with a considerable amount of suspicion. The debt of Ceylon is so light as to attract no attention, and the greater part of her irrigation capital has been drawn from revenue. Mildura should have an excellent influence when sufficient time has elapsed for its financial results to be gauged, but even its enterprising managers are understood to have had an unreasonable difficulty in getting their prospects appreciated by financiers here and at home. Colonial irrigation has to justify itself, and those connected with it, therefore, must be upon their mettle in order to redden its balance-sheet above reproach. This does not imply that special consideration should not be given to the enterprise in its earlier years, and while its novelty tells against it, even with the farmers, but it does remind us that the new departure is to be judged by its profit and loss account, and that this will influence not only the tax-payers who are not irrigators, but those who make advances to us for the prosecution of reproductive public works. In this respect India has the advantage. The Madras schemes are debited with 3½ per cent and the others, except Bombay, which takes 4 per cent. as the cost of its money, reckon at about 3½ per cent., or at least one-half per cent less than ours are debited with under the law. Judging by recent events, no very early reduction of the rate below 4 per cent is to be hoped for in Australia.

Something requires to be said of the Water Supply Department, a bureaucratic service which, though not free from faults, has an honorable record, and will certainly compare favorably with any other department in India. It adds greatly to the ease of administration, though it multiplies its perils, that the clients affected belong to a subject race, and that the vernacular journals do not appear to have yet developed that critical faculty which makes the press in Anglo-Saxon communities occasionally a means of mischief, but on the whole a most efficient and invaluable spur to administrative lethargy and favoritism. The public

spirit, incorruptible integrity and tenderness to the natives exhibited by most officers is highly creditable to them and to their country. So far as each is judged by a passing stranger they do their work admirably, and considering all the circumstances of the case inexpensively also.

But perhaps the best criticism of the Indian system of sole State responsibility is to be found in the constant efforts to mitigate it. Wherever possible a village is dealt with as a whole and required to settle the distribution of water and all disputes arising from it. From Ceylon to the Punjab we find this practice pursued wherever feasible. The headmen, as they are termed, in all settlements, are invariably encouraged to become answerable for the main administration, and, as has been seen committees, or panoh mahals, are especially created for the purpose of inundation canals. In every way legislation strives to throw upon the residents of each locality the task of settling their own affairs, and of securing protection to the canals as common property. Even in the independent territories similar methods of local government, on a small scale, have sprung up, testifying in the strongest and clearest manner to the necessity which everywhere exists for it in connection with irrigation. It is not too much to say that so far as circumstances permit the Indian system is being approximated to our own, though still conveying a very limited authority indeed to the ryot; that the associations of irrigators in France, Italy and America represent the development to a higher form of the same principle of local responsibility; and that the Victorian trust system as it now stands is their ideal, and the ideal of irrigators all the world over. Advances of cheap money for the construction of works, chosen and managed by those dependent upon their supply, represents as near as possible the perfect system for white farmers. Those who oppose it seek to diminish the responsibility of the people concerned, and to cast them upon the general body of taxpayers, just as members of shires created and authorized to raise rates to make roads and bridges ask that they may be built for them by the Public Works Department. There are instances in which an appeal to the public purse is valid in each case, but they are few and special. There is no just and no sane principle for the distribution of public funds, except that they should be expended to benefit ratepayers in proportion to their contribution, or to the urgency of their special need. Local expenditure should mean local taxation, to raise the necessary sum, or pay interest upon it; any departure from this means the reduction of politics to a selfish game of grab. If the Australian is to cast all his responsibilities upon his Government he must endow it with power equal to its task, including power over himself and his property, which would render him in some respects a mere ryot. If he accept the privileges of freedom and free institutions, he must bear his burdens for himself in common with his fellows, and in conjunction with them. The alternative is to yield both burdens and freedom to the State.

In arid Asia irrigation has been an essential, and whether in Persia, Afghanistan, or the region to the north of them, and whether in ancient or modern times, has supplied in a large measure the means of maintenance to its peoples. The oasis of Turfan, according to a Russian report published in *Nature* of this year, contains colossal works of the same character as those of Ontario and other places in California, bringing the water to the surface by means of tunnels or of wells sometimes 300ft. deep. Sir Colin Moncrieff recently visited a part of the Russian territory where there are still to be seen remains of vast schemes constructed in a remote age but it is understood that his report is unfavorable to any extensive attempt to reconstruct them. The canals and tanks of India were not undertaken for profit, nor yet merely to increase an established prosperity but under the terrible pressure of necessity. Of course the production of the country cannot be indefinitely increased by such means, but it can be rendered fairly even, guarded against adverse seasons, and a reserve provided by means of an artifi-

* If Mr. Deakin means the Government of Britain, as contradistinguished from the Government of the Indian Empire, we should like to know if he is correct. Only in rare and extreme cases, such as that of Jamaica when in a state of ruin, are loans to colonies or possessions imperially guaranteed. None of our Ceylon loans have this guarantee.—ED. T. A.

cial water supply. Irrigation in India spells immunity from famine; there its mission begins and ends; and by this knowledge every one of its phases must be interpreted. The threatened failure of the Kaveri, and the actual failure of the Godavari supplies, led to the initiation of works in the South, while the several stages of irrigation progress in the North were marked in each instance by the recurrence of famines. That the schemes have been made to pay on the whole, and that the expenditure taken in the aggregate leaves good interest, is satisfactory, but it must be admitted that the State is in every case more lenient than private proprietors would be, and that taking into account the charges, the frequent remissions, and the princely scale of many of the schemes, the marvel is that so favorable a result is secured.

Our own circumstances have offered but a faint reflex of these; we have had water famines, and we always shall have a considerate Government, abundantly content if it receives interest upon its advances to the farmers. But there the likeness ends, and it will not be until our population multiplied many times over, comes to press upon the means of subsistence with a terrible intensity, that we can conceive the same urgency for expenditure on water supply for agriculture as has existed in Asia. Our irrigation is undertaken to develop new cultures, and especially highly priced products, such as fruit and wine, while at the same time steady farming generally, by guaranteeing pasture for flocks and grain for the mill, in droughts as well as in propitious seasons. This being the case there is no need for any undue haste or excited adoption of undigested projects. We have made a good start, and what remains is to develop our water resources quietly but unceasingly, on sound lines. This is not to be done in an instant; indeed, it is a work that will never be absolutely finished. The best executive officers reckon that their practice is altered materially every five years. Indian engineering is thoroughly progressive, and so keen are the wits, and so restless the energy of those employed upon it, that they are always leaving their former achievements behind, and pushing on to better things. It is not simply that each generation, brief as is its stay in the country, improves upon its predecessor, but the same officers confess that they have learned to avoid errors, to cheapen construction, and to make administration more efficient. There is now nearly a century of accumulated experience to work upon although the great undertakings have only been commenced in the latter half of it, and still there is a buoyant confidence in the accomplishment of larger successes than have yet been gained, which is in itself one of the most encouraging features of the system, and a bright augury for its future. Although State directed and State controlled, there is no visible stagnation among the professional officers of the Water Supply Department. Australia will do well, therefore, not only to secure the present experience of the empire but to take care to keep abreast of its development from time to time.

To sum up then, the legislation of India has not much to teach us, its administration little, its practices little, its relations of State department and people little, its agriculture very little, but its methods of construction, management of canals, conservation and distribution of water can teach us a great deal. The circumstances out of which irrigation began are not unlike ours, but we may hope that its final outcome with us will be very unlike that which it is reaching in Asiatic realms, where it provides fresh food fast, only to find the population increasing faster, and not permanently rising, or likely to rise, in the social, moral, or intellectual scale, to even a European standard. Given a rational and equitable riparian law, a generous encouragement to farmers who enter upon new culture, or face the outlay necessary to prepare their land for irrigation a keen supervision of trusts by the department, and an intelligent criticism by their constituents of all their proceedings, coupled with such study and practice at our agricultural colleges as shall solve local problems in a practical manner, and there need be no doubt of the future success of irrigation. The French system

of small holdings, Italian skill in dairy farming, American methods of co-operation and enterprise in making markets are well worth acclimatising, as are Indian engineering designs and devices. The outcome of the writer's observations in India are at least as stimulating and encouraging as those which six years ago were embodied in his report upon the irrigation of Western America. Clearly existing systems have much to teach us, and it will be well for us if Australia, the last continent to be colonised by white men and the only one built up solely by Anglo-Saxons, should come to be noted for its openness to new ideas, its freedom from the prejudices of custom, its readiness to adopt improved practices wherever they can be found, and its progressiveness even in agriculture. Our people have been commended for the warmheartedness of their welcome to strangers. But if they can become as well hospitable in thinking, methods of working and mode of living, acclimatising and assimilating the best of all that has been and now is, they will make no ordinary history and merit no ordinary reward.

THE DUTCH MARKET.

CINCHONA.—The 4,533 bales and 229 cases Java bark in sale on December 21st at Amsterdam contain according to the published analyses, 17,350 kilos. sulphate of quinine, or about 4.34 per cent on the average, in the manufactures' bark and 506 kilos. in druggists' bark.—Cocoa-butter: Contrary to their former policy, Messrs. Van Houten and Zonen, the cocoa manufacturers, have sold in the last two auctions (December and January) their produce without reserve. The price declined as far as 51c in December (average 55½c), and 53c in January (average 54½c). The market has become rather unsettled consequently, and although the buyers of cocoa-butter at the last auction could realise some profit, the present value being 58c a ¼ kilo, it is probable that the market will follow the same course as in 1886, when Messrs. Van Houten sold also without reserve, until the value had gone down to 35c. It is scarcely to be expected that the consumption, which is a limited one, will increase in proportion as the price falls.—*Chemist and Druggist.*

COCONUTS in North Borneo bear in five years, and the betelnut palm in four years, but the demand is so great that coconut trees in bearing in Sandakan let for \$2. a year each. We understand that Mr. Abrahamson has leased 500 acres at Kudat for a coconut plantation.—*British North Borneo Herald.*

THE SALE OF CEYLON GOLDEN TIPS IN MELBOURNE is thus referred to in the *Australasian* of 16th Jan., the tea being, however, described as Indian:—

Some very high prices have been paid of late for small parcels of fancy tea sent to London, and a small lot of Indian which has been sent to Melbourne was sold at auction on Tuesday by Greig and Murray Limited at the highest price at which tea has ever been sold in this part of the world. The parcel consisted of only five pounds, and was described as Indigenous Golden Tip Flowery Orange Pekoe. Four pounds was packed in a glass case, and the other pound was packed in two tins; and the selection of the leaves has been going on for the last three years. A large number of those interested in the tea trade had assembled in the saleroom. The first bid received was 10s. per pound, duty paid, followed by bids of two guineas and three guineas per pound. The next advance was to £3 5s per pound, and after successive advances, at first of 5s per pound each, and afterwards of 10s per pound, the parcel was finally knocked down at ten guineas per pound. The purchasers were Messrs. Alfred Harvey & Co., acting on behalf of the Mutual Store, by whom it is understood the tea will be kept for exhibition.

THE TEA ROLLER PATENT CASE.

(Continued from page 501.)

Messrs. Withers and Wendt appeared for the plaintiff (Mr. Wm. Jackson) and Messrs. Browne and Dornhorst for the defendant (Messrs. A. Brown and the Commercial Company), when the case was before the Court on 17th Dec. last Mr. Jackson underwent his examination in chief, and today he was chiefly cross-examined. As on the previous occasion there were a number of models of tea machines were on the table in front of the bench. At 2 o'clock, at which hour it had been arranged that the case should come on, only Mr. Withers and his client were present, and a conversation took place between the Judge and the former as to whether the case would be continued tomorrow and the next day. At a later stage it was understood that the case would be taken up tomorrow afternoon and Saturday.

Mr. Jackson examined by Mr. Withers said:—Before I invented this improved arrangement for transmitting motion I had seen nothing like it in any tea machinery in or out of Ceylon, nor even read of it. I keep a record of all patents taken out for tea machinery; and I searched amongst these, and none of them disclosed this arrangement or any thing that could be called its equivalent. I now look at the defendant's machine—Brown's triple action tea roller—and I point out that the lower rolling surface of that machine answers to the square lower rolling surface of my machine (the Excelsior). The cylindrical drum or case of Brown's machine corresponds to the square case of the Excelsior. The cylindrical top rolling surface of the triple action machine answers to the square rolling surface of the Excelsior. The plain spindle of the triple action roller answers to the spindle of the Excelsior roller, which is screw cut. The bracket of the triple action roller answers to the bracket in the Excelsior in so far as it controls the central spindle and keeps it in vertical position and through which pressure is applied to the top surface. The manner in which the defendant's machine and mine is fed is identical. The leaf in the triple action roller is passed in through a hopper attached to the jacket or cylindrical drum which corresponds to the hopper attached to the square jacket of the Excelsior. Asked about the driving mechanism of the two machines he said:—In the triple action roller there is a vertical crank shaft having two cranks in it, the upper one of which is attached to the jacket or drum. In the Excelsior there is a similar vertical crank shaft, the upper crank pin in which is attached to the square case or jacket. As an expert I say that the arrangement for transmitting motion to the top rolling surface in the defendant's machine through the circular jacket that surrounds it is identical with the arrangement for transmitting motion to my square rolling surface through the square jacket that surrounds it. If the belted arrangement of the defendant's machine were taken off, the two machines would be identical in their action. (This the witness illustrated by working the models.) The use of the belt is to give a rotary motion to the upper surface on its own axis. I have seen Mr. Brown's machine worked on estates upcountry without the belt. No one in Ceylon or anywhere else has ever questioned my right to the exclusive privilege of that invention, since the date of the letters patent in 1881. I qualify the statement I made on the previous day to the effect that since I had taken out the patent for the Excelsior I had sold about 800 Excelsior machines in Ceylon. What I meant to say was that I had sold 800 machines embodying the principle of this invention. I have sold about 126 of the Excelsior itself.

Cross-examined by Mr. Browne, Mr. Jackson said:—I was apprenticed to Messrs. Hall, Russell & Co., Aberdeen. They are marine engineers, and I am not aware of their having made any tea-rollers. I left England and went to Calcutta in the end of 1869 or 1870. I was not more than three hours in London and did not see any tea-rollers there.

I was in Assam about two years as a planter. It must have been somewhere in 1872 when I left the Scottish Assam Company. I took out my first patent for a tea-roller in 1871 or 1872, while I was still a tea-planter; it was nothing like any of these. I patented fourteen or fifteen machines in India.—The culmination of your career as an inventor in India was a lawsuit with Kinmond & Co.?—The beginning of my experience, not the culmination of it. That lawsuit was going on in 1877; when Kinmond called for two rules against us, we called for three rules against him. Each obtained two rules. (Mr. Browne then quoted the result of that suit from vol. 1 page 75 of the Calcutta Law Reports, the witness remarking that the report there was correct.) That case did not go to the Privy Council.—Well, Kinmond having beaten you in that and his specification upheld, did you acquire any of his patent rights or lease them?—Yes, he came to and asked us to continue making our machines under a license from him. The Standard machine was involved in that litigation. Kinmond could not claim that as his patent. Here I must make a little explanation. Kinmond was the original inventor of a tea-rolling machine in India. Both Kinmond and myself were novices at taking out patents. Kinmond's first invention was held to be a combination patent for a machine. The four subsequent patents—two by Mr. Kinmond and two by myself—were repealed by the Court on the ground that they claimed to be patents for new machines and not improvements on machines. Kinmond's first invention—made I think in 1865—consisted of a lower table or surface with a smaller surface superposed above it, this upper or smaller surface being enclosed in a sort of loose case or jacket. The Standard roller was held to infringe that invention for a machine on the ground that it had a lower rolling surface with a smaller one above it, enclosed by a loose case or jacket. The effect of the litigation was that I could not have continued to manufacture the Standard except under Kinmond's license for eighteen months. Only one of these Standards came to Ceylon. The profit went to Kinmond, I am sorry to say, and I want to get that money from him. I saw that Standard machine last Friday on Loolecondura estate, and I produced the name-plate which is inscribed "Jackson's tea-rolling machine, No. 387, manufactured under Kinmond's patent by Marshall, Sons & Co., Ltd., Gainsborough, England." The brass plate which was on the model of the Standard machine on Loolecondura estate, exhibited last court-day, bore "Jackson's tea-rolling machine, manufactured under patent 34." I took the name-plate off the Loolecondura estate Standard, because the machine was in dispute. I had heard that Mr. Alfred Brown had been there with his brother and photographed the machine. In Kinmond's original machine the lower table was raised up by chains and weights at the four corners.—And that is the principle adopted by you in the Standard?—In so far as the lower table in my machine was moved up and down. Kinmond's first machine had also a loose jacket and an upper rolling surface driven direct by cranks. The originality of my machine lay here. Before the Standard no machine had a trap-door for the discharge of the leaf, and there was no machine by which the bevel-wheels could be altered in proportionate size. (Mr. Withers here interposed a remark to the effect that they were trying the Indian case over again, and Mr. Brown retorted that he was testing Mr. Jackson as he was entitled to do and would do in every way he could.) The leaf was discharged through the bottom rolling surface by means of a trap-door. That arrangement was my invention and it was not in Kinmond's machine. In the Standard machine a feeding platform was put on the top through which the leaf could be inserted between the two rolling surfaces. That arrangement was not in Kinmond's machine. Kinmond had no elastic pressure on the under surface of his rolling table beyond what was given by the weights, and I put springs under my lower table. Kinmond's machine was fed by lifting up the jacket and pushing the leaf underneath. Before the Standard there was no rolling machine which had two

rolling surfaces moving at right angles to each other. I do not think any machine had the lower table traversing and the upper stationary. As I have said the Standard had the two surfaces moving at right angles to each other, and each surface being operated by a separate crank-shaft enabled me to put on wheels of uneven or unequal size to produce a varying action on the tea leaf which was then thought necessary. The Standard was the only one of my inventions, which I brought into Ceylon prior to the Excelsior for which I took out a patent in 1881. I never patented the Standard in Ceylon. I first saw the defendants' machine about May or June last year. I had not seen it at the manufacturers' in Scotland, but I got specifications and drawings about July 1890 I think. I got the specifications first and the drawings afterwards. As regards the Excelsior, what I claim as novel in my invention is the arrangement for transmitting motion to the top rolling surface through the case or jacket surrounding it, whereby the top rolling surface is left free as regards vertical movement from the mechanism operating it. The square piece of wood on my machine is the top rolling surface. In the specification it is described as usually composed of wood. It is capable of being moved up and down at the will of the attendant.—And if the attendant has no will about it but has gone to sleep or is having a cheroot outside, is not its vertical action by gravity?—is not its natural motion downward by gravity?—Yes, gravity is the natural force that drags it down. I claim for it that in this vertical action it is entirely free from the driving mechanism.—That is the pith and marrow of your claim, is it not?—No, it is not.—Then what is?—The arrangement of transmitting motion through the jacket to the top rolling surface. Free vertical movement of the top rolling surface is one of the results flowing from that arrangement.—Will you say that it necessarily flows from the subject of your claim?—I cannot add the word or keep it away. It is one of the results flowing from it, but there are other results named in the specification which may not necessarily flow from that arrangement. The machine might be badly put together. It does not follow that the result necessarily flows. I cannot say that it is a necessary result or otherwise, but it is one of the results that flows from the utility of the invention. Then you claim it only as a result of the invention and not as part of it? In Kerr's case I think you took the opposite view.—I am not aware that free vertical motion was claimed, and in speaking of this free vertical action it must be taken into consideration that this was a machine having free vertical action as against the other having no vertical action. I take it for granted that in the specification of my machine the spindle is not mentioned and in the drawing there is only shown a hole in the bow through which a spindle might pass. The spindle, itself is not drawn. In figure 1, there are dotted lines from the bow to A, which represent the spindle and as a matter of fact the first Excelsior that came to Ceylon had both bow and spindle. (Mr. Brown here read part of Mr. Hutson's evidence at the last trial.) Witness then said:—A few small hand-machines were sold without either bow or spindle for cheapness. If the chain of my machine is unhooked the rolling surface may drop down to the bottom, or if the tea gets into a lump it may force the cap to rise somewhat, but it has no automatic action. The mechanical description of it is a controllable action vertical or downwards. Describing the case or jacket of his model he said:—The case or jacket consists of a wooden case with a brass frame, to which is fixed a bow or bracket. (Mr. Brown here called the witness's attention to the description of the jacket given in his specification.) In figure 1, B—the case or jacket enclosing the rolling surface—is that part of my model which is made of wood. There is no lettering in the drawing on that part of my machine which in my model is made of brass or metal. The drawings indicate that that part of my machine which in the model is made of wood is adjustable vertically within the metal frame to which

it is attached: it indicates it by showing the slot-holes through which pass the bolts which secure the lining to the frame. There is no mention of the frame in my specification, separately from the jacket. There is no mention of the materials of which the jacket is to be made. I describe them all as the jacket or case. Up to the present time our largest machines of this make have wooden lining inside as all the machines at first were made. The frame round it has never been made of wood but of cast-iron. One of the objects that influenced me in improving on the Standard was, the weight of the jacket resting on the table below. The weight of the wood and iron composing my Excelsior jacket is from 6 to 8 cwt., of which the woodwork would weigh about 24 lb. The weight of the Standard jacket is about 1 cwt. 9 lb. I would explain that the Standard (Loolecondura) machine takes a charge of 125 lb. of leaf at a time and that the Excelsior takes 300 lb. We are comparing a small with a large machine. To increase the Loolecondura machine to take 300 lb. would cause its present weight to be increased twice or three times, and this increased weight would destroy the under table in no time. When the Court resumed Mr. Jackson said he should like to make a little explanation with regard to part of his previous evidence. He was then asked whether the letter "B" referred in any way to the iron (or brass as in the model) frame, and he replied "No," but he wished now to say that he referred to the whole thing as being "B." Continuing his cross-examination he said:—The power in my machines is transmitted through the pulleys, through the shaft, through the bevel-wheels and then through the boss on the bevel-wheel to the crank-shafts, and through the jacket to the top surface. That is the driving mechanism. The motion is conveyed to the pulley (R) by means of a belt. The power is then taken through the driving shaft (Q in the plan), then through the bevel-wheels (P and N), through the crank-shaft (M, L and R), K, L, M being the three crank pins on the said crank shaft. The crank-pin M is inserted in the boss of the bevel wheel marked N. The crank pin L transmits motion to the lower rolling surface marked G. K is the upper crank pin which transmits motion through the case or jacket to the upper rolling surface. Asked what was the furthest object to which motion was given in the machine he said:—It is difficult to say without seeing the full machine. My machine as a whole is a piece of mechanism. The crank pin L gives to the lower rolling surface G a reciprocating motion. If I remove the upper rolling surface of the Excelsior from its bearing I may then turn part of the driving mechanism without moving the under rolling surface at all, or I may put the driving mechanism in such a position that the under surface will not move at all. The motion imparted to the under rolling surface G is a reciprocating motion which is obtained by an unique crank-shaft which when disconnected from any of its bearings is utterly useless.—Is not the motion which this crank-pin gives to the lower rolling surface a circular motion, suppressed by the lower rolling surface being borne in rectilinear guides?—There can be no circular motion. It is purely a reciprocating motion.—Does a crank give anything but a circular motion?—The crank-pin is doing otherwise just now. (The witness illustrated his answer by moving the model.) It is moving in straight lines revolving in its own axis. An uncontrolled crank pin travels round the crank in a radius in proportion to the size, but the pin is revolving in its own axis.—Does it give a circular motion suppressed by these guides, yes or no?—I cannot answer the question yes or no. I cannot be lulled into using words to suit opponents' counsel. I say that the crank pin transmits a reciprocating motion to the lower rolling surface. The motion which A (the top rolling surface) receives is a reciprocating motion. A reciprocating motion is a motion given in straight lines backwards and forwards. "A" has the same reciprocal motion as what I call the case or jacket has.—That reciprocating motion that "A" gets is a horizontal motion?—Horizontal when the machine is not charged with leaf. When the

machine is charged with leaf it may rise vertically under the charge of leaf. The motion transmitted to it is a horizontal motion. "A" receives its motion from the jacket or case surrounding it—What part of the jacket moves "A."?—I must explain that questions are being put to me which I cannot answer yes or no—Mr. Browne said he would give him every opportunity of answering.—We do not make tea-rolling machines to run empty. We make them to do work and when they are full of leaf this outer case or jacket gets worn away on all sides. The parts that keep it in position on the front and back sides wear away quickly. I cannot say therefore that one side causes it to move one way and the other the other way. This outer jacket contains a surface and drives it. In the model it is the side of the jacket from which it moves that propels it forward; the central spindle keeping it steady.—I believe you do not claim transmission of motion by the spindle?—I have got a jacket on my body, but I do not describe the sleeves and the pockets, but I describe the whole thing as the jacket.—Do you or do you not claim transmission of motion to "A" by the spindle?—No, I do not specify it.—In your action against Kerr you thoroughly disclaimed that any motion was given to "A" by the spindle?—I cannot remember what I said in that action.—Did you not claim there that the spindle was simply a guiding rod?—I believe I did, as a guiding rod which I believe I explained could be so strengthened as to act as a driving rod. I also said that in the model there was not a particle of horizontal motion communicated to the top rolling surface through the vertical shaft or spindle.—"A" is dependent for horizontal motion on what it receives from the jacket. Which part of "A" first gets the motion?—It all receives motion at one time.—If I were to expand the box round "A" so as to leave say an inch of an interval how would it get its horizontal motion?—I never tried it and won't try. Is it not the edges of "A" that receive the horizontal motion from "B"? The whole of "A" receives its horizontal motion from the case. The jacket communicates the motion to the upper rolling surface "A." The upper surface is contained in the jacket and when the jacket moves the upper surface moves with it.—How does the jacket make it move? I cannot explain more fully than I have done.—Does "A" receive its horizontal motion through its edges or sides from the sides of the box or jacket?—I cannot explain it more clearly than I have done. The jacket or case is part of the machine. It may be described as a part of the mechanism or otherwise. Motion is transmitted through the jacket to the top rolling surface (A) and so far it may be said to be part of the driving mechanism. It not only drives "A" but contains the charge of leaf being operated on, and it permits of controllable movement to "A."—Is it part of the driving mechanism for other purposes than driving "A"?—There are no other purposes connected with the jacket which require driving.—The only use of what you call the jacket is to drive "A" and contain the leaf? I have already explained.—When what you call the jacket is lifted off the crank-pin and you apply the motor power will the lower table move? The lower surface will not move unless the whole machine is in complete form. I have never applied motive power to any incomplete machine for the purpose of trying to get it to move. Mr. Jackson here remarked that the effect would be illustrated by taking the fourth wheel off a carriage and then trying to drive home in it, or taking a wheel out of a watch, and expecting it to go. One of the differences between the Standard machine and the Excelsior is that in the Standard "A" drives the jacket and in the Excelsior the jacket drives "A." In the defendant's machine the horizontal motion of what corresponds to "A" in the Excelsior is received from the spindle? That is so, the spindle being carried by a double bow or bracket attached to the cylindrical drum.—In the Excelsior "A" is a perfect working fit to the jacket that surrounds it?—"A" is placed loosely within the

jacket and it is a working fit in so far as it can be moved freely up and down. In the defendant's machine there is an interval of about two inches between what corresponds to "A" in the Excelsior and the jacket round it. "A" in my machine must touch the jacket round it. I have never seen it touch in any of the defendant's machines that I have seen, and I have seen seven I think. "A" in my machine in its reciprocating motion, moves always in the same direction to and fro.—When the belt is attached in the defendant's machine to the pulley on the spindle, "A" in it is caused to revolve?—Yes, it revolves inside the cylindrical drum on its own axis. If I were to take away the woodwork round "A" in the Excelsior as it is patented the bow would go with it?—Yes, but that is a mere detail of construction.—If I were to take away the woodwork and the bow with it would not "A" be moved about by the metal work?—I have never contemplated such a state of things.—"A" would not in these circumstances have the operation you now design for it?—I do not know what operation "A" would have inside a box of that nature. I can only give my opinion on a machine that is complete. I would explain that the jacket consists of the various parts of which it is composed. If any one of these parts are taken away it would be taking away a part of the machine described as the jacket. Witness then proceeded to describe what a bearing is. It consists of a piece of turned iron, or metal inserted into a hole freely and easily, so that the piece of metal may be allowed or may have permission to revolve freely in the hole. Witness's attention was called to the second paragraph in the specification and he was asked.—Will you show on your model the bearing that connects the upper crank pin to the top-rolling surface?—To enable me to show this I must refer to the specification and drawings. I point out the bearing on the model. The specification has the following words in it "K L M" are three crank pins on the crank shaft, K being attached to the rolling surface A, through the case B. The drawing clearly illustrates how this is done. The bearing is not directly or immediately attached to "A" itself. Yes, I said that the driving mechanism in the Excelsior is connected directly to the jacket at the upper crank-pin by the bearing there.—But the metal work of what you call the jacket is part of the driving mechanism is it not?—I must speak of this as a whole. A pulley is made up of four arms and a rim to it. As engineers we speak of a driving pulley as a whole piece in the same way as I referred to the case or jacket as a whole piece. The metal portion is a part of the whole. The metal portion and other parts composing the whole may be considered a part of the driving mechanism or otherwise. One part of the driving mechanism is connected with the other by means of the upper crank pin "K." The lining of wood forming part of the case or jacket is placed inside the outer frame and secured to it by screw bolts. What I have done in my machine is simply that I have described a circle through the working of two straight lines. If I put a sheet of paper between the upper and lower rolling surface and suspend it there free from each, a pencil attached to each surface would mark straight lines. In the machine as it now stands with the upper driving belt removed the pencil would describe a true circle. If a sheet of paper were put between the two surfaces of defendant's machine independent of each of them, and a pencil were attached to each of them, each pencil would describe a circle about 6 inches. A circle would also be described on a sheet of paper put under the horn plate.—So that the motion of Brown's machine in every part throughout is rotatory?—It is not rotatory or rather it is rotatory and eccentric. The two surfaces of the Excelsior move in straight lines at right angles through each other. (Mr. Browne said that in the defendant's machine the upper rolling surface in motion was about one-third of a circle he thought behind the lower.) In your machine as patented did

"A" roll a single leaf of tea?—No single leaf of tea could have been rolled without "A." That is the same as saying that no part of the leaf could be rolled unless the machine were complete. If I were to shut the bottom of the jacket holding the leaf so as to convert it into a box and set the machine at work it would not roll the leaf. The friction necessary to impart a roller twist to the tea leaf is obtained in the Excelsior by two superposed rolling surfaces, these two surfaces being made of a shape so as to utilize as far as possible the friction given from the surfaces to the charge of leaf being operated on. The upper surface therefore not only is made heavy to give the necessary pressure on the leaf being rolled, but it will be seen from the drawing that it is hollowed out on the under side to make it act as the upper rolling surface.—Is it more than a weight on the tea?—It is a rolling surface.—If the jacket were raised in height so as to contain a weight of tea equal to the weight of "A" would the machine roll any tea?—The leaf would be partially rolled. It would not be a successful tea rolling machine because the charge of leaf in such a deep case could not get all turned over during the process of rolling. We are now substituting convex caps for the concave ones. That is to effect better circulation of the leaf. In using the concave caps in the machine as patented I did not find that when the lid was not occasionally raised the tea blocked in the box and stopped the working of the machine. Nor did I find that it stopped the partial rolling of the tea. I never knew it doing so to such an extent that it actually stopped the motor power. Of course if the motive power is not sufficient to drive the machine when charged with leaf and the full pressure applied, I could easily understand the whole thing stopping. Would an 18 ft. by 2 ft. 6 waterwheel give sufficient motive power with a plentiful supply of water? I could not say without trying the actual experiment or working out the actual power of the wheel. The horsepower required is in proportion to the pressure applied on the leaf, the quantity of leaf in the machine and the speed at which the machine is driven. One horsepower will turn the machine at a very slow speed. Ten horsepower would drive the machine at an excessive speed if applied to it. The words in our catalogue are "about 4 horsepower would drive the machine but it is always desirable to have a good margin in motive power." My object in suggesting that margin is based on the principle that if you give a horse a full load to pull on the street every day you will soon kill the horse. The same thing will arise with an engine or other motor if it is too small or too light for the work. I have known a nominal six-horsepower engine as made and supplied by Marshall, Sons & Co., England, running three of our Excelsiors in India; I have no actual experience in Ceylon of how many machines one of these engines will drive. A nominal six-horsepower machine may develop an effective 18-horsepower or 24 if you like. So that these three Excelsior rollers you mentioned had from 5 to 8 effective horsepower each to work them? I did not say that the engine was not doing other work. I cannot therefore say what effective horsepower was imparted to each of the rollers. I should say between 3 and 5 horsepower in proportion to the work being done. The horsepower required depends upon the size of the machine, its construction, and length of stroke. I have seen several of Mr. Brown's machines at work and so far as I know they are uniform in size. I really can not give the power for them any more than I can give the power for my own machine. In this connection I would like to explain that the triple-action roller is about equivalent in size to our Universal or second size Excelsior, and I should say at a guess takes the same power to drive it. Have you known instances where estates have sold off your machine and replaced them by defendants? I know of one estate in which three of our Excelsiors were not sold but removed to another estate belonging to the same Company. I have not ascertained the reason for that, although I have an idea. Was the vertical motion of "A" first applied by you in the Excelsior

to tea rolling machinery? Does this question refer to Ceylon or all over the world? It refers to an answer in Jackson v. Kerr. Mr. Jackson—I was the first to use free vertical movement to the upper rolling surface free from the mechanism operating it. Had Kinnmond in 1877 patented a machine in which the upper table had a traversing motion and vertical motion and descended automatically within the jacket surrounding it? He has in India. I cannot define free vertical motion as a principle. There is nothing new in principle discovered now-a-days or very seldom discovered. Is it a principle or is it not? It may be a principle. I will admit for argument's sake that it is a principle. I am aware that a patent cannot be obtained for a principle. Is not free vertical motion of the upper rolling surface the object of your patent and the driving of the upper rolling surface by the jacket the means of obtaining it? My claim is "the arrangement of transmitting motion &c." as in my specification, stopping at the words "surrounding it." The free vertical motion to the top rolling surface is permitted by the arrangement described in the claim. Why did you take the trouble to specify one of the results? I cannot give any reason beyond this that the claim is clear and distinct and one of the results is given. I drive my jacket directly from the driving mechanism. The jacket is a part driven right from the crank pin or through the crank pin. The driving mechanism of the Excelsior roller may be said to end at the upper crank pin "K" which transmits the motion to the top rolling surface "A." It may therefore be said that the jacket is really not any part of the driving mechanism, but is a part driven by the mechanism. Do you claim to have patented the usual means of converting circular into reciprocating motion? Mr. Jackson—I object to the question on the ground that an importer is deemed an inventor in Ceylon. I therefore cannot disclose what I may or may not have patented.

Mr. Browne:—Oh I am referring to the Excelsior. Mr. Jackson.—That's a different thing. With regard to that I refer to my third claim in the specification. And does it—the third claim—patent the usual means of converting circular into reciprocating motion? If it did that, sir, I would not have taken out a patent or applied for one. I applied for a patent for an arrangement, new at the time, for doing so. That was part of the invention described in my specification and illustrated by the drawing.

In reply to his counsel Mr. Jackson said:—The jacket of my Excelsior is the last part of my machine directly moved by the driving mechanism. Its office is to keep the upper rolling surface in position and carry it with it. Really that is the invention which I claim. Free vertical movement is one of the objects I had in view in making the invention but it is not the subject. It was by detaching the driving mechanism from the upper rolling surface of the Standard and attaching it to the jacket in the Excelsior that I liberated the upper rolling surface so as to allow it free vertical motion under control. Vertical motion is part of a process rather than a principle. In my model here of the Excelsior the wooden lining of the jacket is carried down past the iron frame just short of contact with the lowering rolling surface. If I took away the wooden lining the charge of leaf or part of it would escape. (Mr. Withers.—Then you would have to change the name of your machine to a "tea waster" instead of a "tea-roller.") To hold a large charge of leaf during operation and receive the energy communicated to it for the purposes it is intended to serve my jacket of course ought to be well braced up and heavy. In the Excelsior machine I was the first to use a bow through which a guiding rod was passed, which guiding rod is used in the Excelsior for the purpose of raising and lowering the surface "A" within the jacket "B." I could raise the surface "A" so as to enable me to feed the leaf underneath. I could see the leaf being operated on through the hopper which enabled me to charge the machine. The bow in the Excelsior as shown in the

model and as made in the machines we supply carries the central spindle which acts as a transmitter of vertical movement and a guiding rod. The size of this spindle is a mere question of degree. It could readily be made twice or three times its diameter within the meaning of my specification and drawings, in which case the upper rolling surface "A" if made the least thing smaller on the sides would become a driving rod as well as for the other purposes stated. In the triple action rolling machine we have a bow similarly attached to the jacket as in the Excelsior. This bow permits of free vertical movement to the top rolling surface for the same purposes as explained in the Excelsior machine. The central spindle is made somewhat thicker and stronger than in the Excelsior, is carried by the bow in proportionately enlarged bearings. A small piece is taken off the outer edge of the rolling surface, consequently freeing such rolling surface from actual contact with the jacket. The central spindle therefore serves in this case the double purpose of carrying the top rolling surface in the same path with the jacket, which is practically the same thing as done in the Excelsior. The jacket of the triple action machine is carried on two crank pins which support the jacket in the same way as a beam and scale is supported in the centre. If these outriggers or horn-plates, or bearings as I call them were taken away there would be nothing to prevent the upper surface getting off its horizontal path. In a similar way with reference to the Excelsior the jacket or upper surface is supported in the centre at one side. To obtain a true horizontal path of the upper surface I use two horn-plates or bearings. The object obtained by the use of the horn-plates or bearings in the triple-action machine is equivalent to what I use in my Excelsior. In the Excelsior roller there is a vertical crank shaft at one side of the machine. In the defendant's machine there is the same thing. In the Excelsior roller the upper pin of the crank shaft is coupled direct to the jacket. In defendant's machine it is precisely the same thing. In the Excelsior machine the surface "A" has a traversing motion over the lower surface exactly the same as the jacket surrounding it. In defendant's machine it is precisely the same thing. If I moved the upper crank-pin from its connection with the jacket in defendant's machine, the upper rolling surface would not operate. I took out my patent for the Standard some six to seven years before the litigation with Kinnond who sought to have my patent revoked because it comprised an invention of his (Kinnond's). I was in London during all that litigation. I did not advise it and I objected to it. The Loolecondra Standard is the only one ever supplied to Ceylon. I was not aware of the existence of that name plate on the Loolecondra machine until the models were brought into the Court, the machines being sold direct by the manufacturers in England. I discovered the existence of this name-plate by observing in Court the word "Kinnond" inscribed on the defendants' model. I then ascertained on enquiry that this Loolecondra machine had this name-plate. The model Standard now in Court was made by Marshall, Sons & Co. Gainsborough, soon after my patent was taken out in India and before the litigation with Mr. Kinnond. It was exhibited at the Paris Exhibition and that was its first journey from England. The inscription appearing on the model Standard here I have never thought of removing or altering in any way. The patent number on it is my India patent number. Mr. Jackson afterwards proceeded to explain that the hopper in his machine served also the purpose of a ventilator. In the Standard there was scarcely any ventilation, this want of ventilation being remedied in the new arrangement embodied in the Excelsior.

By Mr. BROWNE.—There was nothing said about ventilation in the specification. With regard to the defendants' machine there may be improved ventilation or otherwise in proportion to the amount of space cut away. Although the hopper is not named as a ventilator in my specification the improved ventilation obtained in the Excelsior was very quickly dis-

covered. During my present visit to Ceylon I have been advising that the caps in the Excelsior should be ventilated, there being nothing new or patentable over what had been disclosed in the Excelsior. I have taken two and a half inches off the outer edge of the rolling surface extending to within a few inches of the four corners of the top rolling surface "A." I have also advised that top rolling surface "A" should as far as possible be made a perforated plate throughout.

Mr. WALTER LAMONT of Messrs. Walker, Sons & Co., Ltd., was then examined:—I am a mechanical engineer and served my apprenticeship in the establishment of John Lawson & Co., mechanical engineers, Glasgow. I was a little over five years with them. I went afterwards to Lees, Anderson & Co. marine engineers, Glasgow. I was in their drawing office for about two years. After leaving them I went to Messrs. Carruthers & Alley Glasgow. There I was engaged in designing machine tools, engines &c. I was there for about two years. I came to Ceylon in 1872 as an engineer to John Walker & Co., Kandy. I am still with the company. For about 8 years I was constantly travelling about estates in Ceylon erecting estate machinery. The first tea-roller that I remember of was imported by my firm about 1877. It consisted of three fluted rollers working two underneath and one on top like a mangle, and the tea to be rolled in it was put into a bag. The pressure of the upper rollers as it turned round rolled the leaf in the bag. About 1877 was about the commencement of the tea industry in Ceylon. That kind of machine I have described was not a success and was sent back again. There were several bag-rolling machines in use about 1879. The first tea-rolling machine which was brought into Ceylon in which the tea was rolled inside a jacket was the Loolecondra estate Standard. That, I think, was in 1879. I saw it shortly after it was erected. The model exhibited is an accurate model of the Standard. The Standard is the only one of its kind that I have seen in Ceylon. In 1881 I became manager of the Colombo Ironworks and in that year my firm imported the first of Mr. Jackson's machines called the Universal roller which is merely a smaller edition of the Excelsior. That Universal was sent up to Windsor Forest estate. Shortly after that my firm were appointed Mr. Jackson's agents in Ceylon for his machines. Our firm has manufactured about 500 of the Economic roller and imported about 300. Of the Excelsior class we have manufactured about 20 I should think, and we have imported about 120. Of Mr. Jackson's machines embodying the principle of the Excelsior we have manufactured and imported about 800 altogether. In 1881 before this patent was taken out the most advanced kind of roller in Ceylon was the Standard. He then pointed out the corresponding parts in the Standard and Excelsior and the difference in the method of driving the top surfaces. In the Standard machine the upper rolling surface is the driven surface and is connected direct to the crank-shaft through a connecting rod. In the Excelsior the jacket is connected to the crank-shaft, and has the surface A free to vertical movement. Before the Excelsior was patented I had not seen in Ceylon any tea roller in which the driving mechanism was attached to the jacket direct, and carried the upper surface with it. The reverse is the case in the Standard. Before the Excelsior there was no machine in Ceylon in which the upper surface was free to vertical movement. Could a practical workman with the Standard before him as a model construct the Excelsior without using his inventive faculties as distinguished from his faculties as a mechanic? No. One of the advantages in the Excelsior machine is that it is much more "get-at-able." The leaf is easily fed into the machine and there is no danger or not so much danger to the attendant feeding it as in the Standard. The case or jacket is off the lower table in the Excelsior, so that there is less friction in driving and the oil used in lubricating the machine is kept clear from the rolling surface. Labour would be economised in the Excelsior. It would

require two coolies to feed the Standard machine for one only to feed the Excelsior. The pressure of the leaf is more easily controlled in the Excelsior than in the Standard. You cannot see the leaf being worked in the Standard roller, but you can in the Excelsior. That in my opinion is a distinct advantage in the Excelsior. There is no ventilation or very little in the Standard and in the Excelsior there is ventilation between the hopper and the cap—through the feeding mouth. It is much better ventilated. Before the Excelsior no machine in Ceylon had the distinct advantages I have enumerated. He then proceeded to refer to the parts of the defendant's machine which in his opinion corresponded to the parts in the Excelsior. The cap or upper rolling surface in defendant's machine corresponds with the cap of the Excelsior. It has free vertical motion in the same way. The jacket in defendant's machine corresponds with the jacket in the Excelsior machine. The jacket in the Excelsior is the whole jacket—the wooden lining with the metal frame. I point out the bow of the jacket. The bow is part of the jacket. The jacket is the wooden lining, metal frame and the bow. When I speak of the jacket of the defendant's machine I mean the frame, lining, and bow which I point out. The hornplates are part of it—cast with it. All these parts constitute the jacket. In the defendant's machine the jacket is driven through the crank pin to which it is attached. In the defendant's machine the jacket carries the top rolling surface; the bow of the jacket carries the upper rolling surface. If the crank pin in the jacket of defendant's machine were taken away the upper rolling surface would not roll over the lower surface. The common advantage in both machines arising from that arrangement is the vertical movement of the upper rolling surface free from the mechanism driving the machine. As an expert do you consider that the arrangement of transmitting motion to the top-rolling surface through the cap or jacket surrounding it which is the invention the plaintiff claims, is adopted by the defendant in his machine? Yes I consider they are both identical.—Yes, our firm have sold several machines of the Excelsior type to the Commercial Company.

Cross-examined.—Our firm are Jackson's agents, working for profit. Our firm is now converted into a limited Company of which I am a shareholder. Our firm sell the Excelsior, Economic, and the Rapid tea rollers as well as others. I am not the patentee of any of these but I took out a patent for a roller after the style of the Economic which is also sold by my firm. I took out a patent for a roller without considering Mr. Jackson's specification very much and afterwards I found out that this patent infringed Mr. Jackson's Excelsior in some particulars. We manufacture it under a license from Mr. Jackson. Then as a shareholder and patentee you have a personal monetary interest in this case? There is no harm in stating that? Oh I don't know. If Mr. Jackson loses his case we (my firm) will not have to pay any more royalty for the Economic. As a mechanical engineer I say that what I call the jacket in the Excelsior is part of the driven mechanism of the machine. It cannot be part of the driving mechanism. What is driven may drive. It carries the cap round with it; it drives the cap. As regards the cap it is not part of the driving mechanism of the machine. It does not drive itself. You cannot work the lower table unless what I call the jacket is connected with the crank pin at the top. The jacket does not help to drive the lower surface. When the jacket is connected with the upper crank pin it does not help to drive the lower surface. Unless the jacket is connected with the upper crank pin the machine as a whole cannot roll tea. If the jacket were taken off the machine we would have in put another bearing on the upper crank pin, in order to make the lower table work as it is now working. That bearing would be attached to the bar. What kind of motion is transmitted in "A"? A reciprocating motion. The motion comes from the crank. On your oath does not "A" receive its motion di-

rectly from the inside of the jacket "B"? What directly touches "A" to move it in its reciprocating motion? It touches the side of the box and the spindle. Assuming that Mr. Jackson disclaims that the spindle gives "A" any part of its reciprocating motion then it is the side of the box or lining that moves it? Assuming that, yes. In making the machines there is a space of about one eighth of an inch between "A" and the lining—just enough to let it move up and down easily. I have seen Mr. Jackson's machine working many times. As the machine moves the side of "A" touches the wooden lining furthest from the direction to which it is moving. In manufacturing machines under Jackson's Excelsior patent we do not make the spindle strong enough to impart horizontal motion to "A" I have seen only one of defendant's machines at work and that was on some estate in Dikoya. In the working of the plaintiff's model of defendant's machine the cap does not touch the lining surrounding it. I cannot say whether it did so in the machine I saw at work. It is about a year ago since I saw that machine in Dikoya. A year ago we knew it was probable that the plaintiff would come to Ceylon to institute this action, but I did not then examine defendant's machine to see whether it touched as described. I am the managing engineer of the firm. As an engineer I say that the horn-plates in defendant's machine are equivalent to the bearings "F" in the Excelsior on which the bar "E" rests and slides. The hornplates of defendant's machine simply rest and slide on the slide plate. They are tied down by the crank-pin. In the Excelsior the bar E is held in the bearing "F" so that it cannot jump out. If I were to substitute for F in the Excelsior straight bearings like those on the defendant's machine, the machine could not be worked because the crank-pin would pull the jacket about in different directions for want of the guide. Is there a difference between the hornplates in defendant's machine and the bearings F in the Excelsior? There is a distinction. The bearing F in the Excelsior machine carries up the jacket and guides it preventing the lining of the jacket from touching the lower surface of the table. The hornplates in the defendant's machine does the same thing—it prevents the lining from touching the lower rolling surface. They rub differently. The plaintiff's bearings guide the motion rectilinearly and the defendant's horizontally so that the upper part of the machines shall not oscillate. The functions of the bearings and the hornplates in the two machines are not therefore the same. You could not substitute each for the other in the respective machines and make the machines work. The motion of each part of the Excelsior is rectilinear and of the defendant's machine, eccentric.

Re-examined.—I said in answer to Mr. Browne that the jacket when connected with the upper crank pin does not help to drive the lower surface. Asked what does it do? He replied,—It takes the power from the crank shaft and drives the upper surface. That which gives the motion to the jacket gives the motion also to that which is inside the jacket. Motion is given directly by the crank to "A" through the jacket. If I removed the horn plates from the defendant's machine the machine would very soon go to pieces.

Mr. FREDERICK MAGUIRE deposed:—I am a mechanical engineer and have had considerable experience of tea machinery in India, Ceylon and Java as well as in the north of Ireland. I was an engineer on tea estates in India. I have been in charge of Mr. Jackson's Standard, Excelsior, and Rapid Rollers in India. I have put these machines up and taken them to pieces. The model of the Standard in Court is, so far as I see, exactly the same as the ones I have experience of in India except in some little details. I have seen the triple-act roller in operation often in Ceylon and the model in Court seems to be accurate. In most of the cases I have seen, it was worked without the belt connecting the cap and the crank spindle. I have read the specification of the Excelsior and

studied the drawings, and the model in Court illustrates that machine in every essential particular. I consider that the Excelsior has the invention specified, the arrangement of transmitting motion to the top rolling surface through the case or jacket surrounding it. In no other class of tea machine have I seen that invention except in the defendant's machine and Law & Davidson's. I do not know when the latter was made but I have seen it in Ceylon. No workman with the Standard before him could have constructed either the Excelsior or triple-action rollers, if he had not a knowledge of machine designing. He then described the differences between the Standard and the Excelsior in view of the invention claimed, and said:—The first and principal advantage in the Excelsior over the Standard is the method for transmitting motion through the jacket to the upper rolling surface, because, in the first place, it enables the upper rolling surface to be lifted, and also it enables the machine to be filled by the attendant standing in front of the machine instead of, in the older machine, having to mount to the top of the roller. Another advantage due to this method of transmitting motion to the top rolling surface is that the machine can be cleaned easier. Then again it dispenses with oiling above the upper rolling surface. I consider that another advantage in the Excelsior over the Standard is that it is a much simpler machine to make; it costs less and does more work. The invention or improved arrangement claimed is, as regards the Standard, a novel one and is the reverse of what obtains in the Standard. In the Standard the upper-rolling surface is connected directly to the driving gear of the machine. In the Excelsior the jacket is connected directly to the driving gear, carrying the upper-rolling surface with it. Having regard to the specification and drawings and the model of the Excelsior before the Court, I consider that the case or jacket as specified in the specification and drawings is as follows:—First, the outer rim, secondly the lining of the jacket, and thirdly, the bow or bracket. All those constitute the jacket together with the bolts and screws that hold these together. The arrangement of transmitting motion claimed by the plaintiff exists in the defendant's machine. The jacket in defendant's machine consists in the same way as in the plaintiff's machine of the same three parts, the casing (the iron framework), the lining of the jacket, and the bow or bracket, the whole jacket being connected directly with the main driving gear—the crank—the same as in the plaintiff's machine. The horn-plates in my opinion are parts of the jacket in the defendant's machine, serving the purpose of carrying the weight off the jacket and thereby preventing friction by scraping or rubbing on the lower rolling surface. The horn-plates in defendant's machine are mechanical equivalents to the sliding rod in the bearings of the Excelsior. More correctly speaking the horn-plates correspond with the rod in the other machine, and the bearings in the plaintiff's machine correspond with the bearings in the defendant's machine. In the Excelsior with a full charge of leaf and the top rolling surface run up as far as it can go and full pressure on, it is the jacket which carries the top rolling surface. According to the specification; in my opinion Mr. Jackson is certainly not tied down to making the central spindle of any diameter or strength; nor is he tied down to making a light or strong bearing in the bow or bracket in which it works. Nor is he tied down by the specification to making the upper rolling surface a working fit to the lining of the jacket. In the Excelsior and triple action rollers the jackets are driven but they drive what is in them. They might be considered drivers as well of the caps within them. The only thing that is really new in the defendant's machine is that the upper rolling surface revolves, which it does not in the plaintiff's; that is to say that it revolves on its own axis.

Cross-examined by Mr. BROWNE.—I worked on no tea estate in the north of Ireland. (Smiles.) I suppose that like myself when you were in Ireland you heard a great deal more of Jackson's *Tea Drum* than Jackson's tea roller? I never heard of one or the other,

I began my tea roller experience in the colonies. I served an apprenticeship as a mechanical engineer, was for six years with Messrs. Wm. Ewart & Sons, Belfast, and then went to Davidson & Co., Belfast, my present employers. I went to Davidson about 1888 and I was about four months in their works. I came to the colonies in the beginning of 1889—first to Ceylon, then to India (where I was six or eight months), back to Ceylon, then to Java (where I was about six weeks) and then back to Ceylon, where I am now. Nearly all the time I have been working for Messrs. Davidson. When not working for them I have been working for others, putting up and looking after machinery. Messrs. Davidson are Sirocco manufacturers. I do not consider the Commercial Company as rivals of my employers as regards Siroccos. At the recent Exhibition the Commercial Company exhibited a machine which they called a desiccator. I do not think that Company import desiccators. I think they are manufactured locally. As far as I know they sell them. They are in the same line of business as my employers. I have studied mechanics as a science in schools in Belfast for three or four years, and I am still studying. I have seen defendant's roller on Mr. Dobree's Dikoya estate. I have also seen it working without a belt on Ardlaw tea estate. I have also seen it on Waltrim and Mayflower estates. I cannot remember any more. I do not know anything about Law & Davidson's machine. Mr. Jackson does not claim any special means for the object he had in view. The transmitting of motion through the case or jacket may be obtained in different ways. Mr. Jackson's object as far as I understand is to give the upper rolling surface the same motion as is received by the case or jacket surrounding it, at the same time allowing the upper rolling free vertical movement. In the Standard the jacket of the upper rolling surface moved in the same direction with great disadvantages. One of the differences between the Standard and the Excelsior is that in the latter the upper rolling surface has free vertical motion which it had not in the Standard. The other differences are those I have already particularised. The sole or only object of Mr. Jackson was not to obtain free vertical motion in the upper rolling surface. That is not in the fore-front of his claim, but follows the transmission of motion &c., I cannot say what his principal object was. His claim I suppose is a particular means and a particular object. The means is the method of transmitting the motion and one of the objects obtained is the release of the upper-rolling table. Jackson in my opinion does not claim to patent free vertical movement to the upper rolling surface, but it is a natural consequence of the first part of his claim. (Mr. Withers interposed an objection to the effect that this was trenching on a matter of law. It was for the judge to decide what the invention was.) I suppose that the clause "whereby, &c." was added to make the claim more distinct and simpler. The relation between the two machines as regards looseness (in the jacket and upper-rolling surface) is different. In the Standard the case or jacket is driven by the four sides of the upper-rolling surface when the machine is working. In the Excelsior the upper rolling surface is driven by the jacket and is indirectly connected to it. Is the jacket of the Standard driven by all four sides of the upper rolling surface at one and the same time? It would be hard to say how it is driven during any one second or instant when it is working. When pressure is on the leaf may roll it on all four sides. In practice with leaf I could not tell you which side touched it instantaneously; the bottom table might push the jacket to any side. I cannot remember the space between the jacket and upper rolling surface in the Standard. In Jackson's the space is about the sixteenth of an inch to allow the upper rolling surface to work up and down—what you may call a working fit. In the Standard the jacket was always loose. In the Excelsior the upper rolling surface is loose to a certain extent but not in the same way as in the other. In the Excelsior the upper rolling surface though loose in the jacket is

suspended from that part of the jacket called the bow. In working the sixteenth of an inch is not preserved on all sides. One side or more of the lining of the jacket is usually in direct contact with the upper-rolling surface. It is the inside of the lining that touches. I have seen some of Jackson's machines in which he has cut away the sides of the upper rolling surface for purposes of ventilation. The corners are always left and the contact is between the corners and the wooden lining. The motion which the lining gives to the upper rolling surface is a knock or push. It is first knocked on one side and then on the other. I have heard the knock on the side of Jackson's machine when working. When I have seen the defendant's machine at work, I have never heard or seen the sides of the lining strike the upper rolling surface. Defendant's upper rolling surface receives its horizontal motion from the spindle and bracket. To constitute mechanism must not two or more bodies be so connected that their motion depends on each other through cinematographical principles alone? I think that means that two or more parts are connected by some mechanical principles, one following the other throughout the train. I think that is what is meant although I never heard the word cinematographical before. (Mr. Browne:—Quite right. He then quoted the meaning of the word from Webster's Dictionary.) I have studied the introduction to mechanics but not under that name. He then traced the chain of mechanism in Jackson's machine and said it ends directly in the jacket. Before the end of the train it transmits motion. One chain of mechanism may transmit motion at various points throughout its length. The first point may either be considered a driving or driven point. The very first point is driven from the shafting that drives it. The train of mechanism is the series of pieces which transmit motion from the driving point to the working part or through them to the ultimate object which is driven only. In the Excelsior the lower rolling surface is one of the series of pieces of its mechanism—one of the working parts. If the guides were not under the lower rolling surface of the Excelsior machine might not work as it would not be complete. If the guide bars of the upper rolling surface were away, the upper rolling surface would work, but I do not think you would have a chance of finding out whether it would be in rectilinear lines because the machine would break up. If you took out the crank pin or sliding bar of an engine you would probably be lying on the floor before you knew where you were. (Shown defendant's model of plaintiff's machine. I suppose it is working as a model all right. If the guide bar of the upper rolling surface were taken out in the model as is now done, the machine being incomplete would not work. I never tried the experiment before on a model. If I were to take out the same part in the Excelsior jacket would it work? If you take anything at all from any of the machines they would not work. The machine would not be complete; it would not be Jackson's machine. It would probably smash up. The engine would be pulling the machine. It would not work for the same reason that an engine would not work if you take away the crank pin. The principal function of the sliding bar of Jackson's machine is to carry the weight of the jacket. The bearing under the horn-plates in defendant's machine would carry the weight of the jacket. The bearings in which the grinding bar rests in plaintiff's machine contain the guiding bar as well as support it. In Jackson's machine the bearings not only support the weight of the jacket but they also act as a guide. In defendant's machine not only an equivalent to bear up the weight of the jacket but an extra guide is supplied. In the plaintiff's machine they guide it in rectilinear and horizontal motion. In the defendant's machine the horn-plates and bearings guide it into a horizontal motion. They keep it from oscillating. They have no other function as directors of motion than that.

Re-examined.—I have seen the upper rolling surface lifted right out of the case or jacket surrounding it while the machine was working, so that no part of the lining was at any given

moment in contact with it. The jacket still carries the upper rolling surface. Motion was then principally transmitted by the bow to the jacket. The spindle might have helped a little.

Mr. C. A. HUTSON, Colombo, deposed:—I am a mechanical engineer and have been practising my profession for about 22 years, 6½ years of that period being in Ceylon. I have seen the Standard, Excelsior, and Triplo-Action Rollers working, and I have erected the Excelsior and Triple-Action machines. I have read the specification of the Excelsior patent, and I consider the jacket of the Excelsior to be the metal frame, the wooden lining and the bracket. The fact of the bow being attached to the frame instead of the wooden lining I look upon as a mere matter of detail. The model I believe to be the same as the working machine. Certainly motion is transmitted through the jacket. In the Standard the upper rolling surface is driven direct from the shaft by the connecting rod, while the jacket slides on it; but in the Excelsior it is the jacket that is driven direct and the rolling surface slides inside of it. The jacket in the Excelsior carries the cap with it, and in the defendant's machine the upper rolling surface is moved by the jacket. I call the jacket in the defendant's machine the cylindrical box and the various parts pertaining to it. I consider the whole thing, including the bow or bracket to be the jacket. In the defendant's machine the action is the same. The jacket drives the top rolling surface. I know Law & Davidson's machine. There the upper surface is not quite free to move up and down. It resembles the Excelsior in the fact that the jacket moves about while the top rolling surface is carried by the jacket and is left free to rise and fall. I think I saw Law & Davidson's machine in 1886—a long time after the Excelsior.

Cross-examined.—A case was threatened, I think, but so far as I know Mr. Jackson has not taken action against Davidson. I gave evidence as to facts in the case Brown, Rae & Co., Hutton, vs. Harcourt Skrine. I was called there as a mechanical engineer to prove that I had examined the machine erected by the plaintiffs for the defendants.—In that case you gave it as your opinion "that the motor has been erected in a correct and substantial manner and that it is at the present moment, able to develop its maximum efficiency"?—Yes. (Mr. Browne, in reply to the District Judge, said that in that case the District Judge held that it was very clear that the machine was not properly erected by the plaintiffs and was practically useless. He read from the judgment.) I have never heard what the Judge said, but I know that Brown, Rae & Co. got all the money they claimed. At one time I was employed by the Commercial Company; they brought me to Ceylon.—And dismissed you afterwards?—No never settled that point. I say they did dismiss me and they say that they did not. I describe the whole thing as the jacket, and its function is to roll the tea leaf. It does that by moving the leaf across the bottom rolling surface and causing the leaf to turn over and rub partly on the top rolling surface and partly on the sides. What I call the jacket is part of the driving mechanism of the machine; it drives the top rolling surface backwards and forwards over the leaf. It also acts as a bearing for the triple crank-shaft and thereby keeps the crank-shaft in position. If the crank-shaft were not kept in position thereby the crank shaft would not work. I can transmit motion from one crank-shaft to another by means of a belt. In the defendant's machine motion is transmitted from the driving crank-shaft to the guiding crank-shaft by the jacket. Either of them would do it; at present both do it. If either were taken off, the part of the machine that was left would work. (Shown model.) That machine is so badly made that it won't work. As a mechanical engineer and I have seen it done though not with the defendant's machine, I say that if the jacket of the defendant's machine is removed, the lower rolling surface will work. (The upper part was taken off the defendant's model of his own machine and the witness was asked to work it.) Plaintiff's mode

won't work any more than that will. The plaintiff's model is a good and true one. It is possible from one crank to drive the other by means of a connecting piece or rod, only that the one crank requires to be balanced a little bit to carry it over the dead set. That is a common motion in threshing machines at home. In the defendants' machine it is carried over the dead set by the upper crank being set at right angles to it and by the two opposing crank pins being connected. The jacket has the motion of the connecting piece or rod. The lower surface has the motion of the connecting piece or rod between the lower cranks.

Mr. A. E. BROWN, examined by Mr. Wendt, who is associated with Mr. Withers in conducting the plaintiff's case, said:—I am Locomotive Engineer of the Ceylon Railway. I have had a general training as an engineer and am an associate member of the Institute of Civil Engineers. I received my training in the employ of Messrs. White & Sons, Isle of Wight, and Messrs. Stevenson & Co., Newcastle-on-Tyne. I have been 24 years in the practice of my profession and have been in Ceylon since 1874. I do not know anything special about tea machinery. I have seen the specification of the plaintiff's machine. I consider the model in Court to be a model of the Excelsior. The case or jacket is the brass frame, the wooden lining and the bracket. In the defendants' machine I find a piece of mechanism corresponding identically with the plaintiff's machine, with the exception that the one is cylindrical and the other is rectangular. The jacket in the Excelsior gives the upper rolling surface motion. It imparts a reciprocating motion. The upper rolling surface is left free to move vertically only. The principle of free vertical motion is embodied in the defendant's machine. The fastening of the bow or bracket is merely a detail of construction, and I do not consider that it in any way alters the principle of the arrangement. It is a small detail of alteration that might have been made to give the bow more rigidity or firmness.

Cross-examined.—The claim I understand is the movement of the upper rolling surface through the jacket. There are certain things that are entailed by the movement of that jacket. By carrying the upper rolling surface in the jacket it is kept free from friction with the lower table. I glanced at the specification in Court this afternoon. The only one of the defendants' machines that I have seen at work was the one in the Racket Court. I have not read the specification of the defendant's machine. Mr. Jackson in his specification calls the jacket the wooden lining and metal surrounding. Speaking from memory in his specification the plaintiff refers in his specification to the lettering in his drawing. I do not think there is any lettering in his drawing on the brass part, but I do not consider that of any importance. I think the brass work would be described by lettering in the drawing inasmuch as the lettering is equidistant from the perpendicular centre line of the drawing. The lettering "B" in plaintiff's drawing, figures 1 and 2, is placed upon the drawing of the woodwork. I see no reason for putting the letter "B" on the metal part. There is no reason for not doing so. That is a matter for the draughtsman. Draughtsmen would not repeat the lettering. I should imagine that for the purpose of transmitting motion from the driving crank-shaft to the guiding crank-shaft the jacket and the lower surface acted as guiding rods. Both must be working to get the proper motion on either. It is necessary that the driving motion of the Excelsior may be effectual that both the jacket and the lower rolling surface should be at work at the same time. The lower surface (after examining the model) will not move without the upper surface. It is also necessary that the jacket should be attached to the sliding bars at the opposite side to the crank-shaft in order to make the upper surface work. It is also necessary that the jacket should be supported by the sliding bar which acts as a guide for the bearings on the jacket to work on. The jacket is acting as a connection between the bearings on the rod and the crank-shaft. If you take away the jacket the

machine is incomplete and therefore will not work. The function of the jacket is to give motion to the upper rolling surface, and to the best of my knowledge that is its only function. It also carries motion through and assists in the working of the lower table. I should think that it was placed there for the purpose of holding the leaf. It carries the leaf to and fro across the lower rolling surface. To a degree the horuplates in the defendants' machine do the same work as the bearings in the other. In defendants' machine the horuplates guide the jacket laterally and in plaintiff's laterally and vertically.

Mr. JACKSON was again examined by Mr. Withers for the purpose of having recorded that what he said had been quite understood in the case. He deposed:—In strict accordance with my patent specification and drawing I have constructed three sizes of machines: the Excelsior, the Universal, and the Ceylon. It is those three classes of machine that I complain has been infringed by the defendant's machine.

By Mr. Browne.—The defendant's machine is nearest the size of our Universal; it is between the size of the Universal and the Excelsior. The area of the Excelsior box is 900 square inches. I have not worked out the cubic contents; it all depends upon how high you make the jacket.

It was then understood that the plaintiff had closed his case, with the exception of some documents which would be put in and perhaps one or two questions.

Mr. WITHERS put in his documentary evidence—letters patent, specification and drawings all of which are filed with the plaint. He also read in evidence the specification filed with the defendant's answer.

Mr. BROWN objected to this latter point on the ground that it could not be read in evidence against them as to whether the defendants had infringed or not. He pressed this specially as regards the case of the second defendant company, that paper not being signed by them and did not bind them—any more than the report of any of the gentlemen of the press. The defendants would be judged by what they had done and not by what anybody else had said they had done. In other words the issue was not what defendant had patented or plaintiff had manufactured, but had defendants' machine infringed that for which the plaintiff got a patent.

Mr. WITHERS said there might be something in that objection if the defendants had made separate answers. They had put in a common answer and any admission that one of the defendants made was surely evidence against all of them. The plaintiff also produced the models as part of this evidence.

Mr. BROWNE said the defendants objected to the plaintiff's model of the Excelsior on the ground as was admitted by plaintiff, the bow or bracket was in the model attached to the metal frame whereas in the specification of patent it was attached to what was woodwork in the model.

The JUDGE also recorded the admission by the defendants that the defendant company had under the license of the first defendant sold the tea leaf rolling machines alleged by the plaintiff to infringe his invention and that these rollers were represented by the models. With this the plaintiff closed his case.

Mr. BROWNE then began his address in opening the defendant's case. He said he should have desired, if it had been possible as regarded the convenience of the Court, that a longer time could have been available to him to digest the mass of evidence that had been led or he ventured to address the Court, but they were hurried here from one case to another, from defamation to infringement, and he could only hope that the remarks he made that day wherever they might be imperfect or even incorrect, would be supplemented and corrected by the evidence of the skilled expert witnesses to be placed before the Court. At the commencement of the case for the defence it was agreed between him and Mr. Dornhorst who with Mr. Loos appeared with him, that he should undertake the responsibility of learning as far as he could the views of his clients as regarded the mechanism of the different machines and of expressing them to

the Court and extracting information in that respect from the different witnesses. One got very rusty over mechanics—almost as rusty as mechanism itself got in this tropical climate. He had had one mechanical case in 1865 in that the Court and another—he thought it was a year or two ago—in the District Court of Kandy, and beyond that he did not know what questions of mechanism had arisen in either Court during the last 20 years. They were at a greater disadvantage here than specialist counsel in London were to whom such cases were a matter of every day occurrence. However, they had to do their best; and for his own part, in his branch of the case he had to acknowledge his very great indebtedness to his client who sat on his right (young Mr. Brown) whom he might call his mechanical junior for all his assistance, in the case. He could not have played any part at all if it had not been for his help. In this matter it was hard to know where to begin. His Honour had been at the trouble for the last four or five days of taking down a mass of evidence that he thought had run to over 100 pages of writing, and now it was his duty to explain to His Honour what the defendant's theories were—they were very simple—in regard to the whole of this case, and to apply the evidence to the whole case and to apply the evidence to them. First let them get as true an idea as possible of each inventor's work, and he thought the result of such an enquiry would be to establish that the two machines were as diametrically opposed to each other in every principle and action as they possibly could be—so opposed that it was almost impossible to think that there could be any similarity, and certainly such a similarity as to amount to an infringement. Mr. Jackson had given a history of how he arrived at what he called the invention of the Excelsior. He had told them that after a training as a mechanical engineer—he (Mr. Browne) took that to be that he was more of a practical than a scientific engineer—he proceeded to Assam. Like Mr. Lamont he seemed to have studied his art in manufactories at home, which, though they had a great deal to do as marine engineers with the rolling sea, had nothing to do with rolling tea. After that experience he came out to India and began life there apparently as a tea planter. There he directed his attention to tea machinery. He told them that there were already rollers in existence, and as far as he (Mr. Browne) could see by what Mr. Jackson had told them and by passages in the report of one case to which he, as Mr. Jackson mentioned, was an unwilling party, most of the principles of the Standard machine were in existence before he took out his license. The patent for the Standard was taken out in India, and Mr. Jackson came here as an expert, and in direct examination told Mr. Withers "I invented the Standard, I took the patent in India for it." He posed before the Court in all the glory of an original inventor, and if his evidence stood uncontradicted without cross-examination the Court would look up to him indubitably as an authority of weight in the matter. The production of the Calcutta Law Reports and his own admissions there were, however, quite sufficient to overthrow that status to which he had raised himself in his direct examination. The one word "Kinmond" on the defendant's model showed him perfectly well that they knew the fallacy of what he (Mr. Browne) might call presumptive assertion that he made in his direct examination. Mr. Jackson admitted that that very machine was involved in the patent case in Calcutta; he admitted that the principle of that machine was one not of 1875 or of 1871 but was one of the year 1865 when Kinmond first brought out his idea, although his upper rolling surface was smaller than this one. Mr. John Brown would tell the Court that he saw that machine of Kinmond's or some machine on that idea which he surmised to be the same as the patent in 1865 or 1868; so that to him it was very clear that there was no warranty for Jackson posing as the inventor of the Standard. Counsel then proceeded to quote the remarks of the judges in the case of Kinmond v. Jackson (Calcutta

Law Reports page 73) with regard to Kinmond's second specification, to the effect that the two important alterations in his original machine which were described in the second specification were the central cavities or recesses and the motion given to the under table as well as the upper, and, that to give motion to the under as well as the upper plate was no doubt an improvement, and had the specification been limited to that it might have been good, but the specification being for the whole combination and not for the movement only it comes under exclusive privileges. This Mr. Browne looked upon as indicating that even in 1877, in the age of the Standard and when the Excelsior was still a thing of the future, both under and upper tables in tea rollers had been given independent motion of each other. Next he referred to Jackson's improvements on Kinmond's machine, and said they consisted of three things. The machine was fed differently, the leaf was discharged differently, and there were springs underneath to minimize the vibration, Mr. Browne supposed, or to make the pressure more automatic. That was the invention; it was nothing more at the best than an improvement in three details, and Mr. Jackson, whatever credit he was entitled to as an improver, could not take up the high stand of genius of the absolute original inventor. With so much credit attaching to him and no more—he was discounting of course Mr. Jackson's value as an expert witness and he was afraid—afraid for his sake—it would be found that by his evidence Mr. Jackson had discounted himself a great deal more in this case—the first, Looecondora Standard, came out to Ceylon and was not patented. Henceforth in Ceylon every inventor or improver was perfectly at liberty to use any part, or any principle he might say, of the Standard machine in his invention. The Standard was never patented in Ceylon.

Mr. WITHERS.—We admit it was public property; common property.

Mr. Browne continuing said that was very important as regarded one thing. In the Looecondora the upper rolling plate was driven direct from the driving mechanism; and what did Jackson do? Jackson said this was a cambrous machine, he could not get at it to feed it properly, and therefore he said he must devise something else, and went to work to produce a different machine. That was one of the reasons that influenced him. Another was the heavy weight of the loose jacket on the under table when it was moving backwards and forwards tearing it all to pieces. He wanted to design something lighter, simpler, and cheaper, and accordingly he went to design the Excelsior roller. He was afraid that the very designing of the Excelsior roller discounted Mr. Jackson's genius a little more. It was, he ventured to say, a very cambrous way of arriving at a result. As they knew from Goodve's Manual of Machines, circular motion was of a compound character and capable of resolution into its elements. Circular motion was produced by two forces which acted as he illustrated by the movement of his hands, transversely. Mr. Jackson got the two forces acting as Counsel had illustrated—a rectilinear force at right angles—and thus, in a quotient to the tea roll, got circular motion. His machine was of rectilinear action throughout. By putting a pencil on it at any part, and using a sheet of paper to record the motion of the pencil, it would be found that the pencil made only straight line. It was a very ingenious idea of his learned friend to suggest to Mr. Jackson that if he attached a piece of paper to the lower rolling surface and put a pencil down a circle would be marked when the two surfaces moved together, and the same thing being done on the other machine it did the same, ergo the two were the same.

Mr. WITHERS was understood to disclaim the credit of that and to say that it was his client who told him.

Mr. Browne continuing said it was a very clever suggestion for Mr. Jackson to make to his counsel to put to him, but it was not presenting the case to the Court in a proper way. It was leading the Court aside from the true construction of the two machines. What Mr. Jackson admitted to him in cross-examination was that if each of the two parts recorded its motion

separately it would record it only in right lines; whereas if each in the other machine recorded its motion on a separate piece of paper it would record it in circular or eccentric lines. That was the truer way to put the different characteristics of the two machines before the Court. Mr. Jackson went all that way round to get a circular result, or, should he say, all the way square to get a circular result. To affect that mechanism, he thought it had been abundantly shown, every part must be attached and in operation—that one part would not work without the other. It had been repeatedly shown in Mr. Jackson's own machine that if that upper part were removed and an attempt made to move the machine, it would do one of two things: it would either get into a position in which the crank would run round without doing anything at all or it would get into a more jammed position in which the crank would not move at all. This he proceeded to illustrate by a model the inventor of the triple-action roller had made, contending that in order to make the whole machine work harmoniously there must be a connecting rod. It mattered not whether the connecting rod was a rod of greater or lesser thickness, square, oblong, or anything else, so long as it made the connection between the one point and the other—between the sliding bar and the crank pin. Mr. Jackson's machine required that principle of the connecting rod, and when Mr. Jackson went into the witness-box and practically asked the Court to believe that this upper metal frame and the wooden box that holds the tea was the jacket and nothing but a jacket, and was not part of the driving mechanism, he was contradicted by his models, by all experience and by his own witnesses. Counsel then referred to Mr. Jackson's evidence on this point to show, as he put it, how completely Mr. Jackson had given himself away, directing the Judge's attention in passing to the circumstance of how often Mr. Jackson answered "Yes" or "No;" how often he began his answers by "I must explain;" how often he gave them as it were a small lecture on a mechanical point, and in the end saying he could give no answer at all. If there was another thing which would tend to discount Mr. Jackson as an expert he submitted most emphatically it would be the way he had evaded his questions. He thought he had two "yeses" and one "no" from him in five hours' examination. He tackled Mr. Jackson three times on the question of the upper rolling surface being a connecting rod and a part of the driving mechanism, and the Judge would see on reading the evidence how he went from bad to worse and in the end actually said it was not a driving mechanism but a thing driven. Counsel quoted several passages in plaintiff's evidence, and subsequently alluding to the deposition of Mr. Lamont confessed he was surprised to find that gentleman agreeing with Mr. Jackson, adding in the concluding part of his reference to this witness's statements that Mr. Lamont's answers were each a refutation of his assertion. Mr. Lamont said the jacket drove the cap but was not a part of the driving mechanism. He said he could not drive it without it and yet that it was not part of the driving mechanism. Surely it must be so. They wanted the driving mechanism to drive every part of the machine, and if they could not do it without this part surely it must be part of the driving mechanism. The other witnesses had gradually progressed for, so far as his memory served, they had admitted this principle. The fact of the matter was that this machine not only resolves circular into rectilinear motion but, if it might be so called, suppressed circular motion. Naturally the cranks in moving would have a tendency to engender circular motion and where the guide opposite was of a corresponding nature circular motion resulted, but when the guide was made rectilinear—and this guide was made rectilinear—and the form of the crank was slightly altered circular motion was suppressed into rectilinear. The crank pin that seemed to be going round was really moving backwards and forwards in straight lines. Even McGuire showed how the guide operated to make Jackson's machine work in a rectilinear motion. Hubson advanced the position much further and Brown even further still. He next quoted from

Raukine's applied mechanics the definition of what was called link work to the effect that the pieces which are connected by link work if they rotate or oscillate are shortly named crank beams or levers. The link by which they are connected is a rigid bar which may be straight or any other figure. The straight figure being the most favourable to strength is used when there is no special reason to the contrary. The link is known by various names under various circumstances, such as coupling rod, connecting rod, crank rod, eccentric rod, &c. It is attached to the pieces which it connects by two pins about which it is free to turn. Now he argued that what Mr. Jackson called his jacket was not a true jacket, and that the metal work of it was a connecting rod in the driving mechanism of his machine. Jackson knew what was coming; he had known of it all along in this case; he had known that it was open to the defendants to take their power off the driving mechanism. He might divert the driving mechanism into as many streams as he liked, and that was the reason Jackson would not admit it. Jackson had gone so far as to do that which his witnesses had contradicted—to assert that it was driven and not driving mechanism. He wanted to take it out of the driving mechanism of his machine, for he knew what was before him, and for the third time when he pressed him Jackson actually jumped over the precipice and said it was driven mechanism alone. Jackson said that the jacket part in the Excelsior was the last part of his machine directly moved by the driving mechanism and its office was to keep "A" (the upper rolling surface) in position and carry it with it. Was that its only office? Well suppose they took it off would the rest of his machine go? Oh, he said, he could not tell. He was like one of those musicians who could only compose a piece of music with the keys of the piano before him and gradually stumbled into the proper chord and harmony. He could not take a sheet of foolscap and sitting down under the shade of a green tree there write down chords of perfect harmony that no mortal ear had ever heard. He was only a practical man and was in the position of Mr. Brown of the Railway who thought the thing would go until he took the machine to pieces and found it would not go. Mr. Jackson's invention was not only a roundabout way of getting circular motion; it resolved circular motion into its component parts and brought them together; but it was mechanism throughout and the jacket was part of the mechanism, and a material part. Mr. Jackson might deny that, but it was patent to the eyes, patent by the evidence, and patent by Jackson's specification. Did Jackson in his specification claim the link or connecting rod of metal as part of his jacket? He never did. The lettering on the drawing showed this; he admitted that it did not load anyone to suppose or imagine that when Jackson spoke of the case or jacket loosely surrounding the upper rolling surface he meant the metal work. The specification was silent about that, and the reason was that it was the connecting rod, a necessary part of the mechanism which it was unnecessary to describe because it was as inevitable that there must be a connection between the two points as it was that the sun would shine that there be day. The lettering was done entirely on the upper part—on the actual container of the tea leaf and the immediate surface surrounding the upper-rolling surface,—and therefore Jackson's specification did not warrant the inference he deduced from it, but on the contrary, taken in conjunction with their reasoning applied to it, with the principles of mechanics, and with the evidence of the expert witnesses, showed that the metal work was not part of the jacket but had the function of a connecting rod.

The Judge:—Can't it be both?

Mr. Browne:—Possibly; as a connecting rod it is utilized to carry the top surface; but even if it had a double function, one of its functions was to act as part of the ordinary driving mechanism, namely a connecting rod for which he had taken out no patent and which it was perfectly open to the defendant to utilize in the way he had done. Mr. Jackson said he wanted to get something light in weight and

light for the planter's purse as well. On a comparison of the weight of the Standard and Excelsior it would be found that there was practically no difference, and what he said was that Jackson got his lightness of weight in the woodwork, only he made his connecting rod of such strength—he supposed Mr. Jackson thought it was necessary—that the whole aggregated up to the weight of the Standard. The great difference between the Standard and the Excelsior was that Jackson took the driving crank off the upper rolling surface which he left free to vertical motion by its own gravity, and getting rid of the top part that was controlling it put it on to the jacket. Instead of moving the jacket about by the upper rolling surface as in the Standard he did the contrary, the advantage that he thereby gained being that he got motion applied directly in the plane wherever it might be at the time whether high up or low down. What the defendants said was Jackson's object in this patent was to release the upper rolling surface and leave it to descend automatically within the case or jacket surrounding it so that he might apply weight to it and use it with much more convenience. The other results following upon that were as Mr. Jackson had stated. Mr. Jackson denied that that was the pith and marrow of his invention, but the proof that it was his object was in his own claim of novelty. "I claim for my novelty the transmission of motion to the upper rolling surface through the case or jacket surrounding it, whereby the upper rolling surface is left free as regards vertical movement from the mechanism operating it." If it was for ventilation, for inspection of the leaf, or for any other of these five or six general purposes that this invention was designed, thought out, matured and put into practice, why were not all those purposes specified in the claim of novelty instead of only the one which was put in the fore-front of his claim, and the one with which they had mainly to deal, namely "whereby &c.?" Jackson foresaw that there was all this difficulty before him, and in his plaint he had left out the words "whereby" &c. He read Jackson's claim, and he asked the Court to read it as a claim for the release of the top rolling surface into automatic action and the transmitting of motion to it when in that state; but he had left out the words "whereby" &c. in his plaint because he saw that not for a single moment was the defendant's machine automatic, being controlled in every part. The defendant's never contemplated free action; they never got rid of the top gear as Jackson did; nay more they retained the driving of their top rolling surface from the driving mechanism of their machine, —and they were free to do that as the Standard had never been patented—and it never touched the surrounding part. Jackson's upper rolling surface was made with a margin of a sixteenth of an inch all round, but in actual motion that sixteenth of an inch was not always preserved and this surface got its horizontal motion by the impact of the case upon it. One of the witnesses stated that when one of Jackson's machines got a little worn he had actually heard the knock as the thing rattled in the box. In the other machine there was in actual working an interval of two inches between the rolling surface and the jacket, and that space was invariably preserved. When Mr. Brown came to look at this machine of Jackson's he saw all its defects and saw how a much better machine could be constructed on entirely different principles. Jackson said there was want of ventilation. Why, Jackson had been copying from Brown's since he came to the island this time by cutting off pieces and leaving only the corners which were necessary for his impact. What he called his upper rolling surface might to a certain extent help the rolling of the tea, but it was not the true principle of rolling. It was really an upper weighting surface on the lower rolling surface, but in so far as the tea was rolled between them it might by courtesy be called the upper rolling surface. Evidence could actually be called to show that unless it were raised from time to time to relieve the tea, the tea would what they called "ball" under-

neath and "ball" to such an extent that not only would this particular part not work but put such a strain on as that it might, as in the case of Begwantalawa he thought, actually stop the turbine. Mr. Brown saw that much better could be done and studied, in all fairness to Jackson and in all due protection of his own interest, how he could do it without infringing Jackson's in the slightest. Jackson, he saw, gave motion to his upper surface by impact of the jacket, but that surface had that this defect, that it did not assist in the rolling beyond being a weight. Jackson's, he said, was a single action roller, and he set to make the triple action machine with the one table going round or waltzing round the other and the chain of mechanism built up so that motion was imparted to the upper surface by the spindle direct from the mechanism of the machine. Jackson's jacket he said was part of the driving mechanism; it was a connecting rod with the case for the tea sunk in it; and the defendant instead of using the case for holding the tea leaf, to impart motion to the upper rolling surface, took the motion direct from the mechanism which he had a perfect right to do, and discarding motion by impact kept his upper rolling surface two inches away from the case. He bore his jacket in the connecting rod and Jackson had not taken out a patent for that. The more they looked into these machines the more they saw their diversity from each other—diversity in construction, diversity in design, diversity in action, and diversity even in original principle; and, taking as an illustration the working of an ordinary pump handle in comparison with the working of a circular handle for the purpose of showing that by its continuous action the latter avoided the loss of power that there was in the former, he appealed to the Court whether he was wrong in describing Jackson's machines as cumbersome by going back to the original principle of resolving circular motion to attain it again instead of beginning with circular motion and conserving it or rather multiplying circular motion. The two machines he contended were wholly diverse, every motion of the one being rectilinear and every motion of the other circular, or, as the other side called it rotatory and eccentric. What Jackson had patented was the transmission of motion, and that motion was obtained by impact, while in the defendant's machine there was no motion by impact, the driving mechanism being continued right up the whole machine and down through the spindle into the upper rolling surface. Of course the contention on the other side was that the whole thing was the jacket and that therefore motion was transmitted to the surface per the spindle, per the jacket. His contention, however, was that what the plaintiff called the jacket was two things; it was the connecting rod—part of the driving mechanism—and the wooden lining was the true jacket. The mere part which was wooden in Jackson's model was the only part that really resembled the jacket of Kinmond's machine; and what he had done was to put that down in the middle of his connecting rod and place a bracket across it simply for grinding purposes. Where Jackson was wrong and misleading was in describing the attachment of the jacket. The attachment of the jacket to the driving mechanism was by the bolts which passed through the slot holes by which, when the jacket was originally made and put in, it was fitted. Some of the witnesses said that the motion of the metal work was the motion of the crank pin, but that was not so, for the crank pin had not only a motion backwards and forwards when suppressed by the connecting rod, but it had a circular motion also on its own axis which circular motion was not imparted to the connecting rod on the top of it. Jackson wanted to make out that the top surface got its motion from the crank pin through the metal frame. He treated it as something like Pyramus giving Thisbe a kiss through the wall. That was not so. He used the word there more as if it were through the strata of the upper rolling surface. In other words the jacket directly moved the upper rolling surface when the lining hit the upper rolling

surface. Was that the way in which the upper surface of the defendant's machine was knocked about from side to side in the horizontal plane? Manifestly not; there was no impact on it all. That was the gist of the whole matter. The description of the metal round the wood was as great a misdescription as Mr. Jackson himself made in the very opening of his specification. Mr. Jackson excused himself for the patent action in Calcutta on the ground that Kinmond and he were novices in drawing out patent specifications, and consequently they fell foul of each other. Mr. Jackson apparently was as great a novice in drawing out a specification as regards the Excelsior as he was at Calcutta. He said: "In carrying out my invention I employed a zig zag crank shaft having three crank pins on it. This shaft I place in a vertical position and connect the upper crank pin to the upper rolling surface by means of a suitable bearing, and in a similar way I connect the immediate crank pin to the lower rolling surface, and the lower crank pin to a wheel or disc turning in a fixed centre." Now in direct examination—there might be no record of the expression because it was so hurriedly or *en passant* uttered—Mr. Jackson, holding his hands for a moment over the machine, said "in fact this is all the upper rolling surface"—treating not only "A" but what he called his jacket as the upper rolling surface too. That was what he meant in the beginning of his specification because the hearing was not connected with this in any way. "K" had only an attachment to this like the attachment of Pyramus to Thisbe, through the hole in the wall; but it was not an actual attachment; it was only a sentimental, a quasi—(Mr. DORNHORST:—A Platonic)—or Jackson attachment. His description was singularly unfortunate in that respect unless they regarded all as the upper rolling surface. One of his first questions to Mr. Jackson was—what is the upper rolling surface?—is it A? to which he answered yes, because he (Mr. Browne knew that when they came to read that with the admission Jackson would be non-plussed when he (Mr. Browne) said where is the attachment of "A" by a suitable bearing, when the question was put there was one of the usual lengthy answers. Mr. Withers in his opening address used words to the effect that the dissimilitude of machines might not prevent one being an infringement of the patent of the other. In a similar way he (Mr. Browne) might say that the similitude of machines might not result in one being an infringement of the patent of the other. For his machine however he claimed that it was wholly dissimilar to Jackson's in every respect. The witnesses had tried to prove various points of similarity, but by his comparison of the models he contended that they were quite dissimilar. When they said that the whole thing was the case or jacket they were really describing the connecting rod and the jacket, and it was clear that Jackson's bearings were not the same as the horn-plates of the defendant. Really Messrs. Browne and Hutton had proved the defendants' case in proving that the frame was a connecting rod. Of the inventor of the triple action roller he thought it would be sufficient to say that he had been, he thought, since 1848 in the colony; at least he began his work out here in 1848 on the hills of Uva, and practically he was directing his attention to Siracces—he dared say Mr. McGuire might faint if he were in Court—and other drying machinery at a time when he supposed, to borrow a phrase from Mark Twain's toast of "the Bahies," Mr. Jackson had no other thought engaging his mind as to the transmission of motion and the purpose to be observed thereby than how to get his big toe into his mouth to suck it as he lay in his cradle. Mr. Browne who was a C. E. saw the grand father of Jackson's machine in 1865 in London—if the Standard was the parent the original idea of the Standard must be the grandfather of Mr. Jackson's machine—and setting to work as a mechanical engineer he soberly devised a machine which he said in no respect infringed Jackson's. He had utilized nothing except what was common property to all inventors, especially Ceylon inventors—the driving of the

upper surface by a crank taken from the driving mechanism. Because he saw it was useful he had retained what Jackson had discarded because he thought it was useless. The design was in his mind for months.—(Mr. BROWN:—Years) for years; and in the end the idea struck him to gear at the train of mechanism a stage higher, put a pulley on it and a corresponding pulley on the central vertical shaft, and the thing was done. With his experience he did not start rashly in life with an action against Kinmond and then practically buy Kinmond's shoes to walk about the world in as an inventor, as the plaintiff did. He started absolutely with his own inventive faculties and invented a machine which he said was original and in no way infringing Jackson's because it did not impart motion to the upper rolling surface through the case or jacket. He believed he would have the advantage of calling as witnesses two gentlemen who were thoroughly scientific mechanics. One of them in his early career passed, he believed, first out of Woolwich, and the other though he was the younger won what might be called the blue ribbon of science at Woolwich in the shape of the Whitworth scholarship. These two witnesses were not merely men of hammer, file and vice, but men who had really studied mechanics thoroughly, and if necessary Kemble, Skrine and others might be called who he thought would bear out Mr. Browne's contention in this case. The first defendant in the case, Mr. Alfred Brown, was at present entitled to a verdict because nothing had been proved against him. So far as he could see the gentleman had needlessly been made a defendant in the case. It was said that he had patented a machine out here and issued a license to the second defendant, to make or use or sell machines, but he did not know that the issuing of that license constituted any cause of action. They had not proved that he had imported or sold a single machine, and on being called he would state that he had done neither of those things. Counsel was ready to admit that Mr. A. Brown had issued license as patentee in Ceylon to others to use the machine, but that was not alleged as a cause of action against him, nor if it were alleged would it make a cause of action against him. In the concluding part of his address Mr. Browne referred to a question of law arising out of Mr. Jackson's affirmative reply to the question that he had applied for an arrangement new at the time of converting circular into reciprocating motion. Well, the defendant's machine did not convert circular into reciprocating motion, and therefore there was no infringement in that matter. Further if Mr. Jackson had patented a particular means or method of arriving at a result he only patented that means, and it was open to the defendant to attain the result in any other way he liked.

Mr. BROWNE concluded his address at 3-15, having spoken for three hours.

Mr. DORNHORST followed on the legal aspect of the case. According to Edmond's work on patents page 217, "an infringement is an act which comes within the terms of the prohibition in the patent," and a patent was "a monopoly granted and contains a prohibitory clause." In order to find out what Mr. Jackson claimed as his peculiar monopoly they had to look at his statement of claim, and there it appeared that he claimed to have discovered a means of transmitting motion to the upper rolling surface. He must stand or fall by that claim and prove that the defendants in their machine transmitted motion in the same way, which he had entirely failed to do, for Mr. Browne had shown that in the triple action the motion was transmitted to the upper rolling surface through the gearing above, and it did not matter whether that idea was borrowed from the Standard or not, as that was common property. As had often been said by Judges of eminence, if the mere fact that certain parts of one machine resembled certain parts of the alleged infringing machine were to be grounds for regarding the attached machine as an infringement of the other, invention would stop; there would be no more improvement in anything. It was necessary in the order of things that there must be certain

things common between two things which tried to attain one result, and the infringement only consisted in one man robbing the other of the particular method which that man's mind had discovered to attain the particular result. The question for His Honour to decide here was whether there had been that piracy on the part of Mr. Browne—whether he had in any way robbed Mr. Jackson of the fruit of his industry and thought by adopting the process for which he had obtained a patent. He then referred the Judge to the case of Curtis and that reported in the *Times Law Reports*, Good-Piva's Patent Cases in 3, *Law Reports* (Chancer Division) and *Law Reports* (House of Lords). As we read that case what it laid down was that where an invention consisted of a particular means of attaining a known result the invention of other means to attain that same known result was not an infringement. Applying that principle to this case what the Judge had to decide was whether Brown had employed the same means as Jackson to attain the known result. He also referred to the case of Bovill, 11 Exchequer, a summary of which was given by Elmoad and which was on all fours with this case. The next case he quoted was that of the Automatic Weighing Machine Co., v Knight, P.O.R., also referred to by Elmoad; and also Ashmand and Greener (Griffin's Patent Cases), and Goswell and Bishop. These were the special authorities he wished to put before the Court, and as showing the principle which always guided Judges in these cases he might refer to *Crossley v. Potter* in McKorie's Patent Cases, namely confining the patentee to the strict words of his specification and to the strict description of the particular invention which he claimed as his own, so that other improvements might not be obstructed and other ingenious and enterprising members of the community might distinctly know what they were prohibited from doing. The guiding principle of courts had been to protect that particular form of property which a man made his own by patent but at the same time not to make that sort of stumblingblock in the way of future improvements and inventions. He submitted that the means by which the machines in this case arrived at the known result were totally different.

EVIDENCE FOR THE DEFENCE.

Mr. JOHN BROWN examined by Mr. Dodwell Browne deposed:—I was brought up as a C. E. I had a great deal of work to do in engineering. Besides my experience in civil engineering I had to do with railways, being assistant to Mr. Gibb on the Aberdeen Railway. That was about 1844-45 and about 1846 and 1847 I was employed by the famous house of Miller, 132, George St., Edinburgh,—in their Edinburgh and London offices—who made about one-half of the railways in Scotland. In 1848 I came to Ceylon. I came out entirely for engineering work originally and have continuously had to do with mechanical engineering since then. I was for six years engaged erecting what was known as the Rajawella Waterworks. In coffee machinery I think I effected nearly all the improvements of any importance which were ever effected upon it. I also have the credit of being the author of "Drying coffee by heated air"—the only process that was ever found successful; in fact desiccating it. I took up the practice of aerial tramways now established in the Uva country in Ceylon, which have proved a great success. I designed the triple-action roller. I did not patent it myself in Ceylon, but I made my son a present of it. I first directed my attention to tea rolling machinery about 1865 or 1866. That was in London. There was no tea in Ceylon then that I knew of. Between 1848 and 1865 I first saw Kinnond's machine in London—a full size machine. Practically it had all the component parts, though not fully developed of the Standard, a model of which I see in court. I first saw the Excelsior roller in 1855 or 1856; that was full size and in Ceylon. I had begun to design tea rollers after seeing that one of Kinnond's in London. In 1884 I had drawings of the triple-action but

they were not anything like complete. About 1866 Mr. Williamsen one of the pioneers of tea in India had spoken to me to see if I could not assist him in tea machinery. The completed triple-action roller was brought out in 1888. Practically I had the idea of tea-rolling machinery since 1866. It took me about three years to see how I could drive the upper rolling surface—to give it rotatory motion revolving on its own axis. In the end I gave it the rotatory motion by seeing that the crank pin if extended had the same motion that I required for the upper rolling surface. It had the same rotatory and circular motions. When I completed my designs for the triple-action roller I was well acquainted with Jackson's Excelsior. The first time I saw Jackson's specification of the Excelsior was I think in 1891. When I saw Jackson's machine first at work on the estates I thought it was wrongfully designed to make a good tea roller. I took particular exception to the method of driving the upper rolling surface because it limits its horizontal motion to that imparted to the case or jacket. I also took exception to the mechanism as being wasteful of power and difficult to arrange. It was my idea that the horizontal motions of the top rolling surface and the case or jacket being identical, was a mistake. The fixed upper rolling surface holding the leaf under pressure prevents the machine from performing its functions. If charged with leaf and a hard rolling pressure applied the charge will not circulate in the box, the top of the charge being held by the stationary lid or upper rolling surface. I have often seen the Excelsior working, and the effect of what I have been saying is that it is necessary to raise the upper rolling surface from time to time to allow the charge to be broken up. If the lid is rapidly raised after rolling under pressure for some time a print (an impression) of the underside of the upper rolling surface will be seen on the top of the charge, proving that the leaf or charge did not move or circulate under the stationary lid. In fact the machine has no top rolling surface. That is not the case in my triple-action roller; it has totally different motions. The top rolling surface in it is continually changing its position both horizontally and vertically and it would therefore be impossible for it to leave a print on the charge—horizontally giving forth circular and rotatory motion. The mechanism of the triple-action is as follows: One of the two pairs of crank shafts are driven by a pair of bevel wheels, and the two opposing cranks on each shaft are connected by strong castings, termed connecting rods. He showed on the model what were the connecting rods, and said everything connecting crank pins are connecting rods; it did not signify in what form or shape. The one connecting rod will not move without the other. That is the mechanism as regards the case or jacket or lower rolling surface. As regards the upper rolling surface the mechanism of it is that the connecting rod imparts circular motion through the double bow bracket which carries two bearings; the bearings impart circular motion to the spindle, to the lower end of which is attached the upper rolling surface. The upper end of the spindle is attached to the lower which regulates its vertical movement. Between the bows of the bracket is a pulley driven by a belt from another pulley carried on the extension of the upper crank pin of the driven crank shaft; the belt connecting the two pulleys imparts circular motion to the upper rolling surface through the spindle. I claim that my upper roller is not free as regards vertical motion from the mechanism operating it. Through the spindle I convey all the movements which the upper rolling surface possesses, both horizontal and vertical, and no part of the upper rolling surface or any of its adjuncts comes into contact with the case or jacket in any way whatsoever. If it did come into contact with the case or jacket I could not drive it; it would cause so great friction that it would practically not be a working machine. By removing from the model of my triple-action roller as I now do all above the lower rolling surface I leave in the model only the lower connecting rod with the lower table resting upon it, and also the hornplates or slidebars which simply

carry the weight which would otherwise fall on the cranks. The horn plates are in no way whatever guides even as regards oscillation. The crank pins would keep the lower table from oscillating. Every pair of cranks connected by a connecting rod has two dead centres. The single connecting rod has also its dead centre over which it will not pass without the assistance of a fly-wheel. (He illustrated this by removing the upper connecting rod in one of his models). Adding to my model the upper connecting rod its mechanism so far as it goes is perfect. The driving shaft has now in its power to convey motion to the guiding shaft. Putting on the upper connecting rod, the other parts of the model except the circular case or jacket round the tea leaf the double bow bracket rests on the upper connecting rod carrying the bearings which carry the vertical spindle. The upper rolling surface there has its horizontal motion complete, also its rotatory motion. The mechanism is complete without the case or jacket and I can now impart motion to the upper and lower rolling surfaces without the jacket. The circular motion is derived from the upper connecting rod through the double bow bracket, thence to the spindle, and thence to the upper rolling surface. The rotatory motion is conveyed to the upper rolling surface through the medium of a belt and the spindle to the upper rolling surface. The principle of the connecting rods is involved in the mechanism of the Excelsior but not in the same manner as in the triple action. The difference is that in the Excelsior the connecting rod is used for converting circular motion into rectilinear motion. In Jackson's machine (Excelsior) the crank driving the connecting rods is a peculiar one in this respect that it has no crank shaft. It consists of three crank pins and two cranks driven by a bearing in the boss of a bevel wheel. The middle crank pin drives the lower connecting rod which carries the table or lower rolling surface. The circular motion of that crank is converted into rectilinear motion through the intervention of guides sliding in grooves. It cannot deviate from the rectilinear movement, it is compelled to move in a rectilinear way. The upper crank pin is connected to the upper connecting rod. The circular motion of the uppermost crank pin drives the upper connecting rod, which is forced to move in a rectilinear line by the intervention of this guiding bar which cannot move otherwise but in a straight line. The two upper crank pins are connected to the two connecting rods in such a manner that those connecting rods may move in their respective rectilinear lines, being in no way fixed to the frame of the machine—the dead part of the machine. The metal framework round the jacket is part of the driving mechanism of Jackson's machine; it must be so. What Jackson calls his jacket, metal and wood combined is really two distinct parts, namely the connecting rod with its guiding bar giving motion to the case or jacket, and the upper rolling surface which is driven by the case or jacket. If I were to remove the lining with the upper rolling surface the mechanism would not be complete; there would be nothing to drive the upper rolling surface. If the wooden lining were taken away and the metal frame left the mechanism would be complete as regards the lower rolling surface, and ready to drive the jacket when it was put back on the machine. I have read Jackson's specification in connection with his drawings. Reading Jackson's specification and plan together I understand the jacket to be the woodwork as delineated in his drawings. The motion which the upper rolling surface gets is the same motion as the woodwork, backwards and forwards. It receives the motion from the sides of the jacket which are in the line of its motion. The first part of the upper rolling surface that receives motion is the edge of it that is furthest from the direction in which it is being moved. It receives its motion from the inner side of the case or jacket immediately adjacent to it. It moves it by impact—by push. You hear the impact in almost every machine after it has been in work for some time; that is when the upper rolling surface gets a little wear and tear, and I

have myself heard it in most of the machines I have seen working. I do not think I have seen above six or eight of the Excelsior itself, but I have seen a good many of the others that are worked on the same principle. Jackson has patented the transmission of motion through the case or jacket to the top rolling surface, and I must decidedly regard that as motion by impact, through the sides of the case against the outer edges of the upper rolling surface. My upper rolling surface receives no motion whatever by impact with anything surrounding it. I call the case or jacket of my machine the wooden portion in plaintiff's model of my machine, surrounding the upper rolling surface.

Cross-examined by Mr. Withers:—I could not say that the Kinmond's machine I saw in London was the subject of the Indian litigation, but I understood it was Kinmond's first patent. Mr. Kinmond has gone over that law suit with me but he did not tell me the arrangement with Jackson. He did not tell me that Mr. Jackson bonded himself to him to sell 80 Standards during eighteen months he at the same time having the exclusive sale of Kinmond's. Would you be surprised to know that Jackson sold not 80 but 160 of that Standard and not one of Kinmond's has been sold since? I do not know about that. I met Mr. Kinmond in London. I am largely interested in tea in Ceylon and have been so for seven or eight years. I am the Managing Director of the second defendant Company. I have had practically the control of machines imported into Ceylon by the Company during the last eight years. My son receives some royalty from the Company (second defendant). Between 80 and 90 triple-action rollers have been sold in Ceylon. Until this law suit was commenced there has been no difficulty I know of in selling them in Ceylon without a guarantee. They guarantee them against Mr. Jackson calling upon them for a royalty. I suppose I never heard of patentees issuing guarantees with the machines. I suppose that the reason is that if Mr. Jackson gained the law suit the purchasers thought they had no guarantee that Mr. Jackson would call upon them to pay a royalty. I say that the description of Jackson's machine in the specification is not a true description. I do not see how you could make it a true description in any circumstances. Assuming that the frame B is part of the case or jacket it is a true description. It would make no difference, assuming that, if the guiding rod were in the centre (drawing of the triple-action produced by Mr. Withers—a copy of the one filed with Browne's specification in the patent office). This is not a correct drawing of the machine as made as regards details. I cannot say whether it is a correct copy of the drawing filed with the specification. (Mr. Withers said that the machine that existed now was different from that on the plan in the specification office). Witness was shown the plaintiff's drawing and deposed. The dotted line inside the jacket represents the top surface "A." He added—Not the whole of it. Only the upper horizontal dotted line and the two bent lines represent the upper rolling surface. The dotted line running up from the centre of "A" represents the main spindle the lower end of which may be attached to "A," "C"—the chain indicates that the top surface is to be moved up and down. The sides of "A"—the upper rolling surface are a working fit. Assuming the drawing to be $1\frac{1}{2}$ inch scale the top rolling surface measure on the plan $4\frac{3}{4}$ inches. Is there anything on the drawing to show that the jacket could not be made round? The drawing is a drawing of a machine having rectilinear motion. The jacket or case itself might be made round. There is nothing in the drawing that "A" could not be made round in the case or jacket but it would be another machine, a drawing is a drawing and represents only what it represents. The letter 'N' inside figure 1 of plaintiff's drawing is marked on the extended boss of the wheel but I would not understand it to mean the wheel. It is put there for a purpose and I would apply it to the boss. If the man wh

drew that plan put the letter N to represent the wheel he is not an engineer. (Mr. Withers remarked that in the specification 'N' is the wheel.) A specification ought to refer more particularly to the class of material make the machine, I know what a drawing is, I have been at drawing for 40 years and the man who put it in the boss and meant it to be wheel was not an engineer. It appears to me that the boss was extended for a purpose was why N is put where it is on the drawing. I say that although in the specification N is described as the wheel, I forget where my first machine was sent to in Ceylon, and I cannot say what number was on it. I recognise a drawing of my machine, but it has evidently been got up for the purpose of a photographer; it is a picture rather than a drawing. (Mr. Browne said he would put Jackson in the box so that the drawing might be identified. Mr. Withers indicated he would not put it in evidence.) In the drawing the upper surface is a working fit, but no machine of mine has ever been made like that, having contact. I know Mr. Jas. Sinclair of Bearwell estate where there is a triple action roller. He never suggested to me that there should be a clear space of two inches all round between the case and the upper-rolling surface. If he did have entirely forgotten, I am perfectly clear that none of my machines was ever made a working fit. The only thing that the drawing discloses is that they were never meant to come in contact with the jacket. At first before it was known the idea was that the lid must rise up between the edge of the upper rolling surface and the jacket so that there was a small space made but no contact. Do the drawings in Colombo or in India disclose anything else but a working fit? Do they show anything to indicate two inches clear space? They do not disclose two inches clear space. At that time we did not know that two inches space would be allowed. A working fit means in relation to the work that it has to do, and the work that this has to do is to revolve inside the case. Had there been contact it would not have been driven. In your drawings in India and Ceylon what space is indicated? About a sixteenth of an inch all round. Mr. Withers—just like the Excelsior. Was there anything in the plaintiff's specifications and drawings to prevent him making the whole upper part of the roller, that is to say, the bow bracket, the lining, and the shell of the upper rolling surface in one piece if he desired so to do. There is everything against it in the specification and in the drawings. Firstly the drawings represent the case or jacket by four letters B. Those letters refer only to that part which is commonly made of wood, and no practical engineer if he had meant to refer to the whole piece would have made the mistake of putting them on that portion. There was, on the other hand, a very good reason for his putting the letters where he did, for he had to arrange for the case or jacket being raised or lowered vertically within what I call the connecting rod. No practical engineer would have called this connecting rod the case or jacket. If the case were in one piece the case would be immovable within the connecting rods. I say that the connecting rods and the wooden parts are two distinct portions each having different functions. My definition of a connecting rod is a bar of iron or any other strong material which may be shaped in any fashion to suit the circumstances in which it is employed. They are of various forms. In the Excelsior it takes the form of being attached to a revolving crank pin at one end and to a guiding rod so that it may be the means of converting circular into rectilinear motion. It could have no other name in machines. In the Triplex the connecting rods are used to transmit a revolving motion from one crank shaft to another. There are dozens of connecting rods. The best definition is to be found in Ranken's applied machines.—Q.—Your definition does not correspond with anything that Ranken says.—However you say he gives a good definition and you subscribe to what he says?—A.—Yes, if he had given the definition I have given his book would have been ten

times its size. (Laughter.) I say that this connecting rod in the tea roller has all the elements of the connecting rod of a locomotive. It has the elements and resembles it in structure—I won't say in appearance because that depends how you look at it. My definition of a "connector" is anything that connects two shafts but it may not be a connecting rod—it may be a belt or a chain. There would be no crank pin involved with a chain or bolt whereas you must have a crank pin with a connecting rod.—Q.—Now, how comes it that in your son's specification the word connecting rod is not used at all?—[Mr. D. F. Browne objected on the ground that what they had written was *ultra vires*—the question being what they had actually manufactured and also on the ground that the witness was being asked a question as to what somebody else had done].—A.—I did not write the specification.—Q.—Did you draw it up or assist in drawing it up?—A.—I handed over the drawings to a patent agent in London in order that he might draw up the specification as there are legal formalities about which I know nothing. I was called to see the specification on mail-day and I was very busy and I did not read it through very carefully before signing it. I simply looked through the claim and saw that was correct. I admit that in the body of the specification the Patent Agent should have been more careful. The drawings are correct; I made them. There was no need to mention the connecting rod in my specification,—the drawings represented it. It would have been useless to put it in the specification (witness shown drawing). Will you tell me how you came by this drawing?—I believe it is my private property. Mr. WITHERS:—It is a certified copy from the Patent office. WITNESS:—There was a drawing put in and taken back. Mr. WITHERS:—Well this is a true copy, certified by the Patent office.—WITNESS: That was withdrawn from the Patent Office. It was put in by mistake.—Q.—Looking at the specification and plan what in your specification is lettered as "K" is it not a hollow cylinder all through?—A.—Well it could not be, if the specification said so the specification is not correct. In the plan the letter "K" is on the connecting rod. Well, the central portion of the connecting rod is a hollow cylinder, and it receives the case or jacket. I don't think this plan is a right one. I cannot tell where it came from. The crank pins here are shown all wrong; as far as I know not one of my machines has gone to India, but the Roller is patented there. The Ceylon specification was made about April 24th, 1888. My son got the patent about the 24th of October. The delay occurred in our withdrawing one plan and putting in another. It may be that my application for a patent in India was not made till the 28th of February, 1889. I don't remember. I cannot say that I have read my Indian specification. A Patent Agent made it out for me and I signed it and sent it. The Ceylon specification was withdrawn with the plan, and a new specification filed. If the Indian specification differs in wording from the local one which you have it is due to that.

Mr. WITHERS said it differed *in toto*.

The Indian specification was never withdrawn; but the Ceylon one was. Oh, I remember, there is a very good reason for it. When that specification for Ceylon was first sent in the leading partner of the house was away from home, and the junior partner, I think, wrote that specification. It was done hurriedly, and when the senior partner came home I think that he and I must have seen these errors and made the specification right. I admit that the language in the two specifications is different but they both relate to the same machine. Q.—I think you will be surprised to hear that the plans sent to India were not the same as those sent to Ceylon? Would you be surprised to hear they are entirely different?—a.—That is an utter impossibility; it could have been nothing of the sort.—Q.—Well, look yourself (I handed plans) Those are not identical?—a.—The machines are identical but the cranks are shown differently and the homplates are slightly different, but they serve the same purpose.

Mr. D. F. Browne said the plan alleged to have been

filed with the Indian specification now produced by Mr. Withers was printed in Aberdeen. Had the other side a certified copy of what was filed in India?

WITNESS:—I always understood that both plans and specifications were the same. How this comes to be printed this way in the Indian specification is a very strange thing. There has been foul work going on here.

Proceeding, witness said:—I don't know if this is a correct plan but this seems to me to correspond with the plan that I believe to be deposited in Ceylon. (Model of the Rapid Roller produced.) This machine embodies the principle of the Excelsior in a way. The upper rolling surface is driven in the same way.

Mr. WITHERS was proceeding to quote from Mr. Brown's alleged Indian specification when

The Court asked what Mr. Withers was reading from?

Mr. DOOWELL BROWNE:—Jolly & Sons' pamphlet, sir. It is a pamphlet printed by Jolly & Sons of Aberdeen.

Mr. WITHERS, holding up a MSS. copy. We have here a more formal copy.

Mr. BROWNE:—Is that a certificate copy of the Indian specification?

Mr. WITHERS:—Yes, it comes from the Indian Patent Office.

Mr. BROWNE:—Is it a certified copy?

Mr. WITHERS:—It accords with the law of Indian evidence.

Mr. BROWNE:—Is it a certified copy?

Mr. WITHERS:—It does not purport to be.

Mr. BROWNE:—Then it is no better than Jolly's pamphlet.

Mr. WITHERS (to Witness):—Is that a correct description of your Indian specification?

WITNESS:—It may be or it may not be. The portions of the specifications now read must refer to the Standard or to the Excelsior,—not to the Rapid. I have seen Mr. Jackson's agent, Mr. Dalgarno, but never spoke to him. I once saw him riding down the road near Bearwell. I never had a conversation with him about tea rollers—never in my life. I saw him and was told who he was when I asked but, I never spoke to him.

Mr. WITHERS said he had no more questions to ask, and the witness was then re-examined by Mr. BROWNE and said: As regards the relation of the jacket and the top rolling surface to each other the Rapid is the same as the Excelsior. Whether the interval between the edge of my upper rolling surface and the lining is two inches or only the sixteenth of an inch there is never contact—there is always an open space all round. I did not sign the specification in Calcutta, I remember now I appointed an attorney there. I don't know by whom it was signed. The plan "ZZ" produced by Mr. Withers is a working drawing specifying the measurements from the office of Messrs. Jas. Abernethy, engineers, Aberdeen. Q.—It is to erect the machine? A.—My private property. Q.—Never mind that; who makes your machines for you? A.—The Agents named in this drawing, James Abernethy & Co., Aberdeen. Q.—And did you ever authorise them to issue such a drawing as this? A.—Never.

The next witness called for the defence was Mr. HARCOURT SERINE, who said—I am the owner of Osborn Estate, Dikoya. I have been planting since 1882. I know Jackson's Excelsior machine, but had never used it. I have used a No. 2 Rapid and also plaintiff's Little Giant Roller. I worked the latter about 2½ years and the Rapid for 19 months. In those machines the upper rolling surface was pushed by the inside of the lining and so got its motion. I bought a Triple Action Roller in 1889, in London, and it was put up here in January 1890. In the Triple Action there is now an inch and three quarters space between the lid and the box. When I had the Triple Action Roller first it would take as a fair charge about 225 lb. of withered leaf. Now, it takes about 270 lb. The maximum quantity the Rapid would take was 150 lb. and the Little Giant about 50 lb. The power necessary for the Triple Action Roller was about the same as for the

Rapid. Witness also gave evidence on one or two points concerning the mechanism of the Rapid stating that the upper rolling surfaces did not roll the tea. Cross-examined, witness said that formerly the space between the upper rolling surface and the lining of the T. A. Roller was only about an eighth or sixteenth of an inch. Afterwards a brass jacket was supplied in place of the wooden one and then an inch and three quarters interval was left and this allowed for a greater quantity of leaf being rolled than formerly when the wooden lining was very thick. Q.—What made you keep a useless machine like the Rapid for 19 months? A.—A useless machine? I did not say it was useless. Q.—I think one would gather that from your answers to counsel in examination in chief. A.—Extreme questions were put to me. I said if the Rapid was carelessly or hurriedly revolved the leaf would not revolve. Q.—I certainly understood and gathered from your several answers that the Rapid was quite a useless machine? Then it was a useless machine? A.—Certainly not. Q.—Did you not get a guarantee with the defendant's machine. I got what I considered to be equally good, I have the assurance in writing that in the event of any contingencies arising I shall be protected. Q.—Did you ask for that? A.—Yes, I asked for it. Q.—Why? A.—Because I had heard a good deal of talk about some litigation likely to arise out of rollers.

Major DAY, R.E., was next called. He said: I am a Major of the Royal Engineers. Mr. Goodlove was our lecturer on mechanism at Woolwich, where I completed my study as an engineer. I left about December 1867. I took second place on leaving. I got gold medal which is given for the most distinguished cadet of season. I have had a scientific training therefore, in mechanics. Our practical course we went through the Royal Arsenal. I was in charge of the printing and lithographic machinery at Chatham when I was Secretary of the Royal Engineers Institute, that was from 1884 to 1889, when I came out here. I had a soda-water manufactory once with all the machinery, and in addition to that I was sent as one of the Travelling Inspectors of Science Classes for the Science and Art Department, South Kensington. This took me to the manufacturing districts a good deal, and I used to meet manufacturers, and generally they went over their works with me, so that I saw their machinery while in the Arsenal; they make everything—from big guns to percussion caps and all kinds of machinery. I have read the specification and studied the drawings filed by the plaintiff in taking out his letters patent from the "Excelsior" machine, and I examined his models and also the model of the Triple Action Roller. In the "Excelsior" the upper rolling surface is moved backwards and forwards by the box by coming in contact with it. (Model of the Triple Action machine pointed out.) The upper rolling surface in the defendant's machine does not receive motion like Mr. Jackson's machine. It receives its horizontal motion by the continuation of the crank-pin upwards, which is fixed to a pulley, and that drives the second pulley by means of a band, and that drives the upper rolling surface. Working the machine as I do not know that it receives two motions. You have got to roll the tea in the box, and it is necessary that you must give the box and the upper rolling surface an isochronous motion, that is moved in equal time; then you also impart this rolling motion by means of these two pulleys and the band. Witness next described the train of mechanism in the Triple Action Roller, and said that with Defendant's Roller it did not matter if the jacket was used or not; the machine could be worked all the same; but with the "Excelsior" the case was different, and the machine would not work without the jacket. In his opinion as an expert motion was not imparted to the upper rolling surface in Jackson's "Excelsior" and Brown's Triple Action in same way; the upper rolling surface of the "Excelsior" would not act if it did not come in contact with the jacket; the bormplates in the defendant's machine were not equivalent to the bearings in Jackson's machine, and could not be

substituted for them. In Jackson's machine there was a guide bar which guided the machine into rectilinear motion.

Cross-examined.—Mayor Day said he was the acting referee to Government as regarded patents, so far as regarded mechanical arrangements. He advised Government on these points, but he had given no opinion to Government about the Triple Action Machine. The train of mechanism would be a gearing which would convey motion from the motor to the object to be moved. The word "Driving" means communication of energy or power to something. That is a good definition. Driving and driven are relative terms, and one implies the other. The jacket in the Excelsior machine is driven as well as driving. It is driven as part of the connecting mechanism. He called the metal frame round the jacket a connecting bar. It was really one. This was driven. *Q.*—Would you really call this a connecting rod, Major? *A.*—Certainly that is a connecting rod. *Q.*—I am talking of the whole of this great picco here. Do you solemnly and sincerely say that all that is nothing more than a connecting rod? *A.*—You can call it a connecting plate if you wish if you do not care to call it a connecting rod. It performs the same function. *Q.*—Would an ordinary mechanic or skilled workman speak of this to his friend as a connecting rod? *A.*—He would call it a connecting rod, bar link, on a plate. *Q.*—Would a man say "Just tilt over that connecting rod" I want to clean the upper rolling surface? *A.*—He would say probably move up the box because that is really the thing that he has any view of when he is going to work inside the work. *Q.*—Will he say "Tilt over the connecting rod?" You say no. He will say "Move the hex." *A.*—You are only taking a part of it. He would say that because he is going to work inside. *Q.*—How do you know he is? *A.*—You said opening it to clean it. *Q.*—Suppose he wanted to turn it over to see if it worked or if there was any stiffness about it. Would he say "Tilt over the connecting rod?" *A.*—He would probably say "Tilt it." (Laughter.) I do not suppose a workman would call it a connecting rod. When a man is working with tea, he calls by quite different names from what a fitter would. The under plate in plaintiff's machine is driven. It is not a connecting rod. The slides in the Excelsior machine restrict circular motion in one direction. They hold the machine tight, so that it cannot go round. It must go in a straight line.

The next witness was Lieutenant FRANK BROWN, of the Royal Artillery, who said that he had gone through both practical and theoretical mechanics in Woolwich Arsenal. He never went through the Academy, but his commission was presented to him for special qualifications. He obtained the Whitworth Scholarship which was open to all the British Empire, for practical and theoretical knowledge in mechanics, engineering, and science generally. It was the blue ribbon of science in England. He had studied under Mr. Fell, of Queen Victoria Street, Patent Agent. He had designed more or less all the Ordnance in the British service under General Maitland. The 380 powder guns, or 23 ton guns now being erected at Colombo were from his designs and he had been sent here specially for their erection. He had studied the specifications of plaintiff's machine, and examined models. Jackson's upper rolling surface was moved by a push which was not the case in the Triple Action machine. If there was contact in defendant's machine, the friction would be too great. Witness next described the difference between technical "rotatory" and "revolving." What plaintiff called the upper rolling surface in his machine he called a weight which could easily be dispensed with increasing depth of the box and filling up the box with tea, the increased head of tea being equivalent to that weight. The jacket was part of the driving mechanism of the machine, and it would not be correct to say that it was part of the driver mechanism. He called the metal work the connecting rod, it did not matter what the form was.

Mr. WITHERS had no question to ask in cross-examination.

Mr. Alfred Brown was called and sworn. He deposed:—I am the first defendant in this action. My father made me a present of the patent of the invention so that I could take the patent here. I am employed at present in the office of the second defendant company. I have not personally imported any of these machines and I have not sold personally any of these machines. I have sold them for the second defendant company as their servant. In my private capacity as patentee I have licensed the second defendant company to do so.

Cross-examined by Mr. WENDT.—I have sold these as the agent of the company. I have a pecuniary interest in the machinery. The license I have given the defendant company is in the form of a letter on condition that they pay a certain sum of money on every machine sold. I believe it was given somewhere in 1888. I think that was before anybody imported these machines, but, can't say positively. It is after the date of the specification filed. I read the Indian specification yesterday afternoon in the Court, not before. I have not seen the Indian drawings. I know these drawings; they are not yet certified by anybody in the Patent Office here.—Are those the drawings which you filed with your specification in Sep. 1888? I thought they were, until I heard yesterday to the contrary. Shortly after the specification was filed, I applied to the Patent Office to alter them. There were difficulties raised against my doing so, and the things were left in an unsettled position. My application to be allowed to alter the drawings as far as I can recollect was about six months after the filing of the specification in Sep. 1888. No difficulty was raised on the original plans in consequence of my application to alter the plans. I never had a definite letter giving me leave to alter the plans, or I should have done so. I can't swear that the drawings filed with my answer have been filed at the Patent Office. I saw the certified copy shown to Mr. John Brown yesterday, but did not look at them. (Z1 shown) I can't give you any opinion one way or the other as to the correctness of the drawings. I should be rather surprised to see these were the drawings filed with my specifications. I have never seen a machine like the one shown in this plan, that is as regards the frame and one or two other details. My experience in any drawings was very little at the time I filed my specification. (Attention to the letter K was drawn.) Hollow cylinder K. No. 3—does the drawing represent what you mentioned in your specification? I have no recollection whatever on these points. I did not refresh my memory because I was told that my specification would not come to Court at all. Were you aware of a copy of your specifications and drawings was filed with your answer in this action? I did not know that this drawing had been filed. I knew the specification was. I myself supplied the tracings to be filed with my answer. I sent half-a-dozen copies of the plan now filed with answer to Messrs. Loos & Van Cuylenburg. I do not recollect any difficulty of any sort raised regarding the grant of a patent to me. Messrs. Loos & Van Cuylenburg only did the legal business, but I did not employ any patentee for the purpose of taking it. My application for leave to file specification was on the 28th April 1888. I filed my specification on the 28th of Sept. 1888.—What was the cause of this delay?—I think that was the usual delay so far as I am aware. There was no reference to me made between the application for leave to file and the filing of the specifications, from the Patent Office.

Mr. WITHERS in addressing the Court on behalf of the plaintiff in this case, at the close of the evidence on Saturday, proposed that they should go direct to the issues in the case, leaving behind them such charming creations of his friend's exuberant fancy as Pyramis and Thisbe working out cinematics across a tea machine and, while continuing to guide their conduct in rectilinear paths suppress any natural tendency there might be on their part to move in a vicious circle. A curve might be more beautiful than a straight line, but it must be admitted that there were advantages in going direct to a point. Assuming that the plaintiff had proved his invention, namely the transmission of

motion to the upper rolling surface through the case or jacket surrounding it, he contended there was abundant proof of its novelty and usefulness. Those competent to speak on the subject had admitted that there had never been in Ceylon before any tea rolling machine which had the same arrangement as this one, the arrangement being the very reverse of that existing in the Standard which had been proved to be the most advanced machine of the class at the time Mr. Jackson took out his patent; and the utility of the invention had been equally well established. The admission had been made by witnesses on the other side that the Excelsior was a useful machine, and witnesses on the plaintiff's side had thoroughly proved its usefulness in respect of the almost total absence of friction, of the upper rolling surface being free to vertical motion, of being more easily fed, and better ventilated, and of being more economical as regards time and labour than any other machine that had preceded it, all these forms of usefulness being derived from the improved arrangement. Asking the Court, as far as it possibly could, to place itself in the position of a mechanical engineer who was offering to the public a machine of a particular class, in language suited to workmen of ordinary skill who were conversant with that particular class of machine, he proceeded to quote from a judgment of, he supposed, the greatest Patent lawyer that ever lived, the late Sir George Jessell, master of the Rolls, in the case of *Hinks v. The Safety Lighting Company* (Law Reports, Chancery Division 667) to the effect.—“I am anxious, as I believe every judge is who knows anything of Patent law, to support honest *bona fide* inventors who have actually invented something novel and useful, and to prevent their patents from being overturned on mere technical objections, or on mere evillings with the language of the specification so as to deprive the inventor of the benefit of his invention. This is sometimes called a benevolent mode of construction. Perhaps that is not the best term to use, but it may be described as construing a specification fairly with a judicial anxiety to support a really useful invention, if it can be supported on a reasonable construction of the patent.” That was how His Honour had to read the patent. The same learned judge in *Clark v. Adie* (Law Reports to Appeal Cases) said.—“In construing the specification we must construe it like all written documents, taking the words and seeing what is the meaning of those words when applied to the subject matter”; and Lord Justice James confirmed that when he said, “Of course in ascertaining the meaning of words used, you endeavour to put yourself as much as possible in the position of the person using them.” That was what he asked His Honour to do in this case—to put himself in the position of plaintiff when he or his draughtsman wrote the specification in 1881. Mr. Browne had asked the Court to hold that the plaintiff's invention consisted of what he had left out of the plant, contending that the pith and marrow of plaintiff's invention was expressed by the words “whereby such rolling surface is left free as regards vertical movement from the mechanism operating it,” and that the defendant had not infringed that because he did not allow any freedom of motion to his upper rolling surface. The language itself showed that that could not be the invention that plaintiff claimed. What plaintiff claimed was “the arrangement of transmitting motion to the upper rolling surface through the case or jacket the clause whereby” &c., meaning that that what it stated was one of the results or consequences flowing from the arrangement. His learned friend said it was singular that plaintiff should be silent in his specification as to other useful results. Well, if the Court read the specification it would find that all the other useful purposes served by this improved arrangement were mentioned. It was stated “enclosing the rolling surface A so that”—this was the result—“it can be weighted to give the required pressure to the leaf.” In the Standard they could not give the required pressure to the leaf but in the Excelsior they could in consequence of this new arrangement. Another useful result mentioned in the specification was that the machine was fed through the

hopper; and then it was stated that “owing to the jacket being carried just clear of the table”—that was also a necessary part of the improved arrangement—“friction, wear and tear is thus reduced” that being another useful result. As to the interpretation of the phrase “transmitting motion through the case or jacket,” he could not understand why *through* should not receive its ordinary meaning of “by means of,” and he should be very much astonished if the court held, as Mr. Browne contended, that *through*, must mean in a transverse sense—straight through preserving the upper rolling surface always in the same plane as the jacket surrounding it. The “dead centre” in the case round which they could not both move harmoniously was the jacket. That was really the only problem the Court had to solve, and that was the reason why he had said and honestly believed that the Court had no need of assessors. The experience of a civil engineer and a military engineer had not necessarily settled the question. Which the Court had to settle was what the engineer who drafted the specification meant as the invention, and it really resolved itself into the little word “jacket.” The passages he would read from the specification would show, he argued, that it could only mean what the plaintiff said it meant, namely the whole of what had been called the lining—the frame-work from side to side, from crank pin to bar, and all that was attached thereto, including the bow bracket. Any workman conversant with tea machinery of this class in Ceylon at the date when the specification was filed could not possibly read it in any other sense than the sense in which it had been read by the plaintiff and his witnesses who were mechanical engineers. He quoted. “In carrying out my invention I employ a zig-zag crank shaft having three crank pins formed in it. This shaft I place in a vertical position and connect the upper crank to the top rolling surface by means of a suitable bearing.” Now, the little error in that expression in itself illuminated the sense of the word “jacket.” The Court would find that this imperfect way of expressing it showed it more clearly almost than if it had been most accurately expressed. He would show the Court how, directly. They knew, and even the other side would admit, that the shaft was in no way connected to the top rolling surface, and, to show what was meant in that connection he would go on to another part of the specification, to the part where it said:—“A” is the top rolling surface usually composed of wood; “B” is a case or jacket loosely enclosing the rolling surface “A” so that it can be weighted to give the required pressure to the leaf and can be raised or lowered within the jacket by means of the chain “C” for the purpose of feeding the machine from the hopper “D” “E” is a bar firing attached to the case “B” and arranged to slide in the bearing “F,” while, together with the crank pin K carries the case “B,” and prevents it bearing its weight on the under table at any time, although the case B actually come nearly in contact with it.” From this the Court could see exactly what the top rolling surface in the first part meant—it meant the whole of the machinery that was superposed above the under table which it came nearly in contact with, in fact, there was no doubt that when the Court read through the specifications it would come to this conclusion. He should refer to it again when he came to discuss the question so much pressed about as to whether it was a part of the driving mechanism, and the end part carried the leaf about in its rectilinear progress to and fro, backwards and forwards, helping to circulate the tea in the course of rolling while the pressure and weight upon it came from the actual lid, or upper rolling surface, but, considered as a whole, the whole of the superstructure, with its lid, frame, box and bow was the upper rolling surface of the machine. This part of the specifications showed conclusively what was meant by the jacket, and there was the last passage he could quote:—“Friction wear and tear is thus reduced, and by slackening the screw S the rolling surface A with the jacket B can be tilted over.” He thought that was conclusive as shewing the sense in which Mr. Jackson used the word and as all working

people would understand it who knew any thing about this class of machinery at the time. The other side desired to confine the word "jacket" simply to the lining. They argued that the lining was as much an integral part of the machine as any other part. But let the Court look at the drawings or at the machine in operation. Let the Court remember that even a hostile interest had said that the lining was merely a collection of loose pieces of wood bound up. It really was almost absurd to say that a bundle of loose pieces of wood could constitute an integral and independent part of the machine. As a matter of fact there was no reason why the whole superstructure should not be cast in one piece. The learned judge might just as well say that the silk lining of his dress waistcoat was the waistcoat and not the cloth outside it, and, according to the arguments of the other side, he might just as well say that the cloth outside it was a connecting rod between the silk lining and the coat outside the waistcoat. The court would remember that in the Standard the driving gear was fixed firmly to the top rolling surface and carried the loose jacket, which actually rested on the lower surface, about with it and of course tore the machine to pieces. To reverse that arrangement and drive the weighted lid through the jacket, it was necessary in order to reduce friction to carry it in suspension just above the surface of the under rolling table and the court would remember that Mr. Jackson had said why he had to make so strong a frame—because it now had to bear all the energy communicated to the driving mechanism, and it had to be made heavy on account of the large quantity of leaf it carried about in circulation, now all the difference between the Excelsior and the triple action machine, reading the word "jacket" as he asked the court to do, was that, whereas Mr. Jackson had thrown the strength of his jacket in that body, they (the defendants) had thrown the strength of their jacket on the top of the jacket so that they might drive it from above. The defendants simply drove from the top of the jacket and the plaintiff from the bottom. The defendants had to drive from the top because they wished to give an independent motion to the rolling surface. The defendants had made much of their improvements, and had even called their attention to the improvement in their machine that this upper rolling surface had a motion round its own axis, while at the same time it had an eccentric motion with the jacket and imparted by the jacket. Let the Court look at the defendants' specification. This was their language there:—"Causing it to revolve inside the hollow cylinder 'K,' while at the same time it has the eccentric motion imparted to it by the hollow cylinder 'K.' They wanted now to alter the word 'by,' in that, to 'of'—a very pretty alteration that would be indeed. The Court would see for itself how clearly that motion was imparted by their jacket as much as it was in the Excelsior. The other side, too, now laid stress on the fact, that the spindle drove their upper rolling surface and he would invite particular attention to the fact that really and truly, even in the Excelsior, the bow not merely guided the upper lid through the spindle but drove it as well. It must be so. (Mr. BROWNE: Jackson denied it.) Even Mr. Jackson could not deny the fact. It must be so, because the lid was constantly coming in contact with the spindle, and therefore it imperceptibly drove it as well as guided it. But this was not enough for their purpose and therefore they put the chief driving power below. In the defendants' machine they had made a proportionately stronger spindle so that the upper rolling surface could be entirely driven through it, then, if the Court held that plaintiff was right in his acceptance of the word "jacket" it was clear that the defendants machine was driven as regarded the eccentric motion of the upper lid by the jacket in precisely the same way as was done in the Excelsior—"though, the jacket or "by means of" the jacket, only the upper part of it instead of the lower. He thought he had finished now the kernel of the question. Now a famous question had been often asked, and Mr. Browne had said that for five hours he could not get an

answer from Mr. Jackson, as to whether the jacket was a part of the driving mechanism. If Mr. Browne were to ask Mr. Jackson till Doomsday he would not get an answer, for one was asking the question on the supposition that what Mr. Jackson meant by the jacket was simply the wooden lining, whereas Mr. Jackson was answering on the assumption that the jacket consisted of the whole superstructure: the Court could see how true their witnesses were in saying that this whole upper part was not a part of the driving mechanism, but was the driven part; what was wanted with the machine was to drive the upper and the lower rolling surface over one another so that really these were the driven parts. Defendants might just as well say any carriage between two other carriages in a railway train was a part of the driving mechanism; because it communicated motion from the carriage in front to the carriage behind it. But was not the driving mechanism of the train the locomotive? What was the object of the locomotive except to drive the carriages? And what was their machine built for except to drive these two rolling surfaces one over the other in a transverse direction? They might just as well call an intermediate carriage in a train a "connecting rod." Fancy asking a guard to "place your bag in a first class connecting rod"! Would the guard understand the request? It would be absolute nonsense. Of course, if the Court interpreted jacket in the same way as defendants did, they would have been talking sense. He was not going to criticise the mechanics, he was perfectly incompetent to do so. Another point on which emphasis had been laid was that plaintiff's invention was simply the use of a connecting rod, which had been known ever since any sort of machinery had been constructed. If this was so, how was it their great rival, Mr. Brown, had not stepped in under the Ordinance and asked the Court to ask the patent authorities to revoke his patent on the ground that all he had patented was an ordinary connecting rod? That would have relieved them of all difficulty; then they might have patented their machine without giving any guarantee. Now, the tea industry was not a thing of recent date. It began late in the seventies, and now they were in the nineties, and he thought they might regard this question from another point of view, and he hoped this would conclude it. He should like to know what Mr. Brown senior had been doing all this time between 1877 and 1888. When they remembered that from 1848 to 1865 his inventive genius was flashing with a series of corruscations in coffee machinery—in fact he understood Mr. Brown today that there was not an improvement in coffee which was not the work of his hand; then he went to the famous Rajawella water works and then flew over to Uva and spun tramways in the air just like a spider—and after that—he did nothing! His client—to quote the language of his learned friend was allowed to come to Ceylon and sell hundreds of machines of this principle and not a movement would be made by his rival, Mr. Brown. How were they to account for that? Did the court not think it might be accounted for in this way:—He thought Mr. Brown had told them his interest in tea estates and machinery began about 6 or 8 years ago. That would bring them to about 1884. At that very time his inventive faculty awoke. They could not get out of the language of mechanics; but the movements of his interest and of his inventions became "isochronous"—they began to vibrate at the same time and then did the Court not think that the desire to have a good machine out and to make money by it would have spurred on his invention and would have quickened his inventive faculties? But no: from 1884 to 1888, he had told them, he was solving the great mechanical difficulty of getting a part of his machine to have the same eccentric motion as the jacket, and to invent pulleys and a strap to give the part an independent rotary motion of its own. He thought there was a little ring of false modesty about that, and he thought that what Mr. Brown was trying to do during these 4 years—and which he unfortunately had not succeeded in—was to escape between the Scylla of the Excelsior, and the Charybdis of the Rapid,

and bring out an invention that would clear the two, and now he thought he had done so because he had made his roller round instead of square, as they had made theirs but chiefly on account of two things, namely, the eccentric motion of the jacket and the upper lid together in the same plane, and the independent motion round its own axis of the upper lid by means of the pulleys. They would give defendants' machine this: they would admit that plaintiff's machine had an eccentric motion, and their upper lid had no independent rotary movement of its own; but that did not give the defendant's any right to patent their machine. For the purpose of argument, he would admit that defendant's machine was very much superior to the Excelsior; and that the differences were improvements, but this was all irrelevant. Defendants must not take over plaintiff's leading principle and improve on that. They might be useful improvements and they might be patentable, but if defendant's were going to patent them, they should take care to distinguish their invention from that described in a prior patent, and claim only what belonged to them. Of course that would not be enough because they would have to get a license from plaintiff or lay themselves open to an action for infringement. They had patented their invention—perhaps these improvements had carried the day for them and they had got their letters patent; but defendants must not use their machine in public without plaintiff's leave if, as he asked the Court to hold, they had taken the leading principle of plaintiff's machine. With the exception of the eccentricity of the motion of the jacket the upper lid and the independent rotary motion the machines were precisely the same. The Court could not look at them without seeing this, and assuming that the Court concurred with the specifications in the way that he said any ordinary intelligent man would construe them, the only authorities he would ask the Court to refer to except the passages he had read in Johnson's Patented Manual, was the well-known case of *Procter v. Bennett*, in Law Journal Chancellor's Reports, vol. 57 and there the question was an arrangement for the automatic feeding and a furnace. As the Lord Justice said, furnaces had been fed ever since the world began, so the object was a well-known object; they had been fed in all kinds of ways, and so long as the way of doing it was new, that was enough. Lord Bowen perhaps put it more concisely; he said "what is the substance of the invention? It is a machine which produces a successful intermittent retring stoker," and so on, and wound up by saying "the simple question is not whether the addition is a material one or whether the omission is material, but you must go back again and ask yourselves whether what has been taken is the substance and essence of the invention." The Court must put all likeness aside. The machines might be exactly like one another, as his learned friend had said, and yet the leading principle might not have been abstracted from them and they might be very different in structure and yet contain the leading principle. If that were so, no matter what the differences were, no matter what was left out of the Excelsior or added to the triple action—if the same idea was in both—then the Court must take the plaintiff's part and prevent defendants from using his machine till plaintiff's license expired. He also asked the court to bear in mind the circumstances under which Mr. Jackson came to Ceylon. He was the pioneer of useful tea machinery in Ceylon, and the Excelsior was a pioneer invention and he asked the Court to bear that in mind. The Court was not to think of India or Java. He asked the Court if this patent had been taken over by defendants as a pioneer invention, and that was a very important point. As Lord Justice Bowen said "Now I think it goes to the root of the case to remember that this as was described, by one is the counsel was really a pioneer invention, and it is by the right of that that it seems to me we ought to consider the question. Whether there have been variations or omissions and additions which prevent the machines which is complained of from being an infringement

of the plaintiff! With regard to the variations, I take precisely the same view that the Lord Justice has taken and I will not travel over the matter which he has gone over in detail. With regard to the additions and omissions it is obvious that additions may be an improvement, and that omissions may be an improvement, but the mere fact that there is an omission does not enable you to take the plaintiff's patent. He had now a very few words to say as to the first defendant's liability. The other side had tried to exempt him from any liability, but by his own mouth he had condemned himself, for he had said he was the agent of the Company to sell the machines, which they imported under a license from him (Mr. BROWN: Pardon me, not the agent for a special purpose. He has not admitted that. He is one of the employees of the Company.) Never mind whether he was one of a hundred or the solitary agent; it was well known in law that an agent could not plead his agency—he was equally within his principal's tortfeasor. It was within his knowledge that these machines had been sold, and he had joined with the Company in their answer, and instead of putting in an independent answer saying he knew nothing about it, he joined with the Company in putting the issue before the Court. If there had been infringement or not it was impossible to say, if the second defendant was guilty that he was not equally guilty.

With this counsel resumed his seat, and the Court reserved judgment.

SOME INTERESTING QUININE STATISTICS.

The following figures show the quantities of cinchona bark offered at the auctions in Amsterdam and London during the year 1891:—

In London (24 auctions) 17,121 packages Ceylon, 17,152 ditto British Indian, 1,393 Java, 1,113 ditto S. American Galisaya, 4,827 of various kinds; total 41,706 packages.

In Amsterdam (10 auctions) a total of 42,520 packages bark, almost exclusively from Java.

The equivalent of sulphate of quinine represented by the total quantity of cinchona sold to manufacturers at the London auctions of 1891 is estimated at 96,378 kilos., and that sold at the Amsterdam auctions (including 15,663 kilos. represented by a large private sale of bark) at 135,395 kilos. The total quantity of quinine bought by all the makers in Amsterdam and London last year is therefore approximately 231,773 kilos., or 8,181,000 oz. With regard to the quantities of quinine in the bark bought by the various manufacturers, the Amsterdam statistics alone offer a fairly reliable guide. They disclose the following result:—

The Auerbach work bought 29,467 kilos. quinine; the Brunswick works, 26,132 kilos.; the Mannheim and Amsterdam works, 16,147 kilos.; the Philadelphia factory, 15,148 kilos.; the New York factory, 12,969 kilos.; Messrs. Howard & Sons, 6,737 kilos.; the Frankfurt-on-Main and Stuttgart works, 6,190 kilos.; Polletier's works, 2,872 kilos.; Tailendier's works 1,700 kilos.; various other makers, 2,370 kilos. To these figures must be added 8,964 kilos. purchased by the Auerbach works, and 6,999 kilos. purchased by other German works by private treaty in Amsterdam. In considering these figures it must also be borne in mind that if the figures for London could be added to those given, the result would reverse the positions of several buyers. The Mannheim factory, for instance, buys more than one-third of the bark sold at the London auctions, whereas the purchases of Auerbach and Brunswick in this market are comparatively insignificant.

The statistics we have given show that Germany bought 93,599 kilos. or 69.1 per cent. of the quinine in the bark sold in Amsterdam. Including the bark ob-

tained in London, German factories purchased 162,010 kilos. quinine during the year—in other words, they would make 5,750,000 oz. of the 8,200,000 oz. of quinine forming the total supply—that is, 70 per cent. This total does not include the direct supplies of bark from the Soekawana and Djajagiri plantations in Java consigned to Brunswick. As already announced, these are now about to be stopped. It may cause considerable surprise, but the statement seems, nevertheless, well founded, that the total consumption of quinine in Germany does not now average over 8,000 kilos, or 290,000 oz., so that at least 95 per cent of the total German quinine-production is exported. The consumption of quinine in Germany has for several years been seriously on the decrease, a circumstance attributed to the persistency with which sundry new antipyretics are advertised in that country. The German factories complain greatly that, in spite of the reduced value of cinchona bark, the railway tariffs for this article have not been lowered, and are about double those of tanning barks, the intrinsic value of some of which is actually greater than that of cinchona. The stock in Amsterdam at the end of the year was 5,279 packages (of which 2,281 were Government bark). The average proportion of quinine (sulphate) in the bark sold in Amsterdam last year was 4.08 per cent, against 4.00 in 1890 and 4.12 per cent in 1889. But among the barks offered in Amsterdam last year no less than 1,000,000 kilos, or nearly two-sevenths, contained less than 3 per cent quinine. The Java planters are strongly advised not to harvest such bark in the future, or, if it must be taken off the trees, to burn it upon the plantation rather than ship it.—*Chemist and Druggist*, Jan. 15th.

CHINA TEAS IN THE SEVENTEENTH CENTURY.

If "you want to have," says the pronouncement of Sir Andrew Clark which has lately lifted up the hearts of despondent chazzees, "tea which will not injure and which will refresh, get black China tea, putting in the right measure—the old-fashioned teaspoonful for each person and one for the blessed pot. Then pour on briskly boiling water, and within five minutes you must pour it off again, or it will become wicked instead of good." Thus summing up the experience of two centuries and his own, as to the virtues of *thea bohea* Sir Andrew bids his hearers beware of the interloping, nerve-destroying Indian plant—advice which, if they are wise, should cheer but not inebriate our teamen of Foochow. While we wait to mark the effect of his most excellent brave words on Ming Lane, it is amusing if not instructive to turn back to the beginning of those two centuries, and see in what light tea was regarded by the primitive teamen, its first introducers to the West. Many of their judgments have been collected for us by their contemporary Nieuhof, whom Ogilby a few years later translated by fulios. This is the result of the observations and experiments of one Athanasius Kircher:—

"There is a plant called *cha*, which not being able to contain itself within the boundaries of China hath insinuated itself into Europe, the leaf being boiled and infused in water the Chinese drink very hot as often as they please. It is of a direct faculty, which fortifies the stomach, exhilarates the spirits, and wonderfully openeth all the nephretic passages or reins. It fresh the head by surmounting of fuliginous vapors, so that it is a most excellent drink for studious and sedentary persons, to quicken them in their operations. Albeit at the first it seemeth insipid and bitter yet custom makes it pleasant, and though the Turkish coffee is said to produce the like effect, and the Mexican chocolate be another excellent drink, yet Tea, if the best, very much excelleth them, because chocolate in hot seasons inflameth the blood more than ordinary, and coffee agitateth cholera; but this liquor in all seasons hath one and the same effect."

The members of the Dutch Embassy of 1655-6 bore very similar testimony. "Such," they noted in their diary, "especially find the benefit thereof who have overcharged their Stomachs with eating, or discomposd their brains with too much strong drink: for

it is a very great drier of gross Humours, and dispels Vapors occasioning sleep. It strengthens the Memory, but increases Gall if drunk in too great quantity. In brief, they extol the virtues of this drink infinitely, and attribute their not having the Stone or Gout to this (as they term it) *Most Noble Drink*; which we may believe the rather, because in all our Journeys forward and backward we met with none that were afflicted with these distempers."

A latter writer, commenting on tea after its introduction into Europe, is equally enthusiastic: "To drink it after meals takes away all indigestion and rawness of the stomach, and causes digestion, makes those that are inebriated sober and restores them fresh power and senses, removes giddiness and pains of the head occasioned by excess of drink, and they that are called upon to vigilancy, by drinking the same expel their drowsiness and become very vigorous and fit for business. It prolongs life also, for if a the night, and is commended by the famous physician Nicholas Tulp for the wholesomest plant that grows." They did not then believe in the "slow poison" theory. But there was (Sir Andrew Clark might answer) no Indian tea in those days.

An impression which even the twenty-years-in-the-country speak-the-language men imbibe is rarely dispelled by these early orders, the impression, to wit, that the Chinese do not take, and never have taken milk or sugar with their tea. The Dutch Ambassadors went to call on "the Third Governor" of Nanking, or rather he sent for them, His wife, by the way, was with him,— "a bold virago," the Dutchmen call her. "The room was presently filled with Tartar gentlewomen, who belonged to and waited on this lady, and brought a great silver kettle full of *Thea*, mingled with milk and salt, placing it in the middle of the chamber and serving it wooden ladles to all the company." Of course it will be objected that these Manohu dames were but following the Mongol fashion of bricktea and butter; and other writers in Ogilby's collection plainly declare that "some Chinese prepare it with milk, and a little salt mingled with water, though, to be sure, they add "this is not so well approved" as the orthodox method. That method is not quite Sir Andrew Clark's, but approximates to it. The Japanese, it would seem, "beat the leaves to a powder and mingle it with boiling water in a cup, which they afterwards drink off. But the Chinese put the leaves whole into a pot of boiling water, which having in in stop for some time they sip off hot without swallowing down any of the leaves, but only the Quintessence thereof extracted.

"Lord Trip" it appears is responsible for the statement that "the Chinese boil the leaves with a little salt and sugar to take away the bitterness," but he also admits that they "put a handful of *The* leaves in a pint-pot, then pour it full of scalding water, and about two or three minutes after drink the same very hot." Modern Chinese by the way do not always conform to this last most salutary, and if we may so speak Clarky system but often brew their 'pint-pot' of tea in the morning, and leave it to stew through the day, taking toll of it every half hour or so. They declare that the practice is harmless, because they do not, like the wasteful foreigner, crowd in the tea-caves. One spoonful suffices for the family, heads are not counted, and there are no tender leanings towards "the blessed spot."—*N. C. Herald*.

WHAT FARMING IS COMING TO.

AN AMERICAN DREAM OF THE FUTURE.

In the *New England Magazine* for November, Mr. C. S. Plumb, vice-director of the Purdue University Agricultural Experiment Station, publishes a fanciful paper. It describes the future of agriculture, an account of which he places in the mouth of a director of an Indiana experiment station delivered in the year 2,000 as a telephonic lecture to the students of the National Agronomic University of France.

ALL SMALL HOLDINGS.

The following is his description of what farming will bowhen science has revolutionised agriculture:—
 Our farms are all small holdings, the largest being fifty acres, while the ordinary size is ten acres. Each homestead is located about ten rods from the asphalt roadway, while the barn (we have but one barn on a farm in America) is located in the centre of the farm. A pneumatic tube running under ground connects the cellar of the house with the barn, so that when having no other means of transit, except to walk, persons may enter the pouch of the tube and be conveyed to and from the barn with electric rapidity. Horses are used by some farmers, but generally vehicles having pneumatic rubber-tired bicycle wheels, with ball bearings, are conveyed from point to point by means of electric motors stored beneath the wagon bed.

ELECTRICITY AND AGRICULTURE.

The influence of electricity on our farming occupation is exceedingly great. Every farmer has an electric plant in his house, which connects with the whole establishment, and not only materially lightens the labour of the women, but assist in farm-work in many particulars. In the house the rooms are lighted by electricity; doors and windows are opened and closed by pressing an electric button; butter extractors are operated by electric power; an inverted brush-box with a handle, worked by a motor, is passed over the floor to sweep, requiring simply the guidance of hand power; dish-washing machines are run by the lightning-like fluid, and likewise the elevator in houses two stories high; all cooking is conducted in electric stoves; and all clothing is washed and ironed by simple, inexpensive machinery, run by electricity.

On the farm, electricity serves many important purposes. Barn doors are operated by electric power; and electric fork conveys the hay and fodder from the wagon to the barn, and from mow to manger; automatic electric shovels clean out the manure troughs behind the cattle; the farm bell is rung by electricity; ploughs, mowing machines, hay tedders and rakes are operated by electric motors; and all animals are slaughtered by means of electric connection. It has been demonstrated that electrically grown vegetables are of superior quality and tenderness. Lines of electric wires distributed through the propagating pits, and even in the fields on the farm, have greatly increased the yield and early maturity of crops, while destroying all fungus growth and insects adjacent to the wires.

INSECTICULTURE.

Everybody possesses apparatus for spraying plants for the destruction of injurious insects and fungi and he would be considered a singular farmer at the present day who neglected to use his insecticides and fungicides. Injurious insects, however, are held in check by many farmers by the use of beneficial insects. On every well-regulated farm are small pens for breeding beneficial insects. Farmers propagating beneficial insects train them to come at the call of a whistle, so that the trained ones are easily collected in the field whenever desired.

The care of our live stock has been reduced to such a science, that seemingly a maximum of profit is secured. Animals of all classes are fed on a scientific basis. By following the directions of the Henri Prescription Book, one is enabled to deposit alternate layers of lean and fat upon the animal carcass, or entirely one or the other. Through our knowledge of the effects of food upon the animal system, we are also enabled to secure nothing but pure cream from our cows, if we see fit, or the reverse.

Automatic milking machines are commonly used here now. None of our American cattle have horns, though two hundred years ago hornless cattle were uncommon.

GROWING MANURE.

Perhaps one of the most important discoveries yet made by one of our stations is the method of pro-

ducing root nodules on clover and other leguminous plants, which contain nitrogen. By a careful system in-and-in breeding we have produced a number of nodule-bearing varieties of clover and alfalfa that yield us great quantities of nitrogenous fertiliser.

The roots, differing from those of ordinary varieties, grow near the surface, like potatoes. At the proper time of maturity they are ploughed out, and the nodules which are of good size are uncovered, dried and ground, thus furnishing a most important source of nitrogen. In consequence of our excessive care and judicious use of manures at the present time, we gather an average of fifty bushels of wheat per acre, where we grew but twelve a century ago, and shell two hundred bushels of corn per acre, where we formerly harvested but forty.

FOUR STRAWBERRIES ONE QUART.

On the same area of land, with a smaller number of plants, to-day we can grow a far larger crop than could be grown one hundred years ago. The plants have been bred with such wisdom, and the soil fertilised with such care, that each plant develops its maximum growth. Our strawberries are of delightful flavour and flesh and colour, and four or five average ones make a quart. The seeds have all been eliminated from our cultivated raspberries, blackberries, currants, and gooseberries. Their fruit is marvellously delicate in flavour, especially so the two former.

In all the centuries man has discovered no more nutritious, stable food than milk, and to-day our dairy interests, with our population of five hundred millions, are vast.

In their relation to the people, the farmers of America occupy a high position. As our constitution provides that the various industries shall be represented in our legislative halls according to the proportion of the people engaged in each the farmers have a leading voice in the construction of our laws, and the social, moral, and financial conditions resulting from their supervision and influence are eminently satisfactory, not only to the farming population, but to the body of our citizens as a whole.

A farmer is not satisfied that a hen lay one hundred eggs of two ounces weight each in one year, eating one bushel of grain to do the same. He rather aims to make the hen produce three hundred and sixty-five eggs in one year, each weighing one-half pound, eating one-half bushel of grain to produce said eggs.

We may as well stop here.—*Review of Reviews*

Colonies and India, in its last issue, published the following remarks:—"It must be gratifying to our planters to find that Ceylon and Indian tea is rapidly driving the Chinese article out of the market in Australian colonies, and Ceylon tea particularly is rising in favour at the Antipodes, and the Indian producer has now much to fear from the competition of the Ceylon gardens. Before long, it seems probable that both John Chinaman and his staple export will be practically excluded from Australian shores."

MANA GRASS BARRELS.—Mr. C. E. H. Symons has sent us for inspection, at the request of Mr. Martin Leake, a small barrel made of paper composed of mana grass pulp mixed with 15 per cent of old wa te paper. This is the barrel referred to by our London correspondent recently, which Mr. J. L. Shand was to have brought with him. Mr. Leake thinks that the Ceylon Government should start a small experimental factory for the conversion of native grasses into boards. Our London correspondent and we ourselves have so often referred to this matter, that we need only say that we quite approve of Mr. Leake's suggestion. The barrel is strong and light, and might be utilized for many purposes.

FACTS ABOUT TEA.

(To the Editor of the Globe.)

SIR,—You were kind enough to insert some time ago a letter from me on the above subject, in reference to Ceylon tea. This letter has been quoted and commented upon in most of the Eastern papers, and I trust, has been the means of calling public attention to the merits of Ceylon tea. I see the subject is again being discussed in your columns, but what I should suggest is that a number of samples of Ceylon, Indian, and Chinese tea should be submitted for analysis to some analyst of repute, and their respective proportions of tannin and theine correctly given. I saw in your paper what purported to be an analysis of those teas in a letter of a correspondent, but I should be sorry to take his *ipso dixit* on the matter, as I believe he was not an analyst. As your correspondent Mr. Hicks says, unless tea is properly made, that is infused for the proper time, the tannin and bitter extractive are brought out. My experience is that Ceylon tea should infuse for seven or eight minutes, but no more. There are many brands of Ceylon tea that can be procured pure, and, as European intelligence and improvements are used in harvesting this tea, it should surely compete with that imported from an Empire that looks with jealous eyes on Western ideas, even when they are good ones. I have no doubt Indian teas will find champions, but they cannot compete with those of Ceylon.—Yours truly,
N. E. YORKE-DAVIES.
January 11.

SIR,—I have read with much interest the letter in your issue of yesterday from a "Tea Planter of Thirty Years' Standing," which throws quite a new light on the question of some of the Himalayan growths of tea, and it is very satisfactory to hear that quality free from the excessive quantity of tannin as found in the lower districts of India and in Ceylon can be produced on the hills of India. So far it has generally been supposed that the difference in preparation between China and other kinds accounts for the freedom from tannin in the one case and excessive quantity in the other, and all lovers of really good tea, with the delicious "tea flavour" possessed by the better kind of China, will be glad to know a similar beverage can be produced from Indian products, but unless the mode of preparation is more assimilated in the process in China, which expresses most of the tannin before the "firing" takes place, I am very doubtful if this desirable result can be attained. Nevertheless, it is worth the serious consideration of Indian and Ceylon growers to see what they can do in this direction, if they wish to preserve their valuable industry, for the time cannot be far off when the medical profession will step in and forbid the use of these unwholesome pungent tannin-laden teas now being let loose on the public at the expense of nerves and digestion. Tea must necessarily be tanniferous, but the less we get of this deleterious property the better, and until they learn in India and Ceylon to get rid of as much tannin as possible during the process of manufacture commend me to the delicious tea flavour and bouquet found so far only in China growth, such teas as you get everywhere in Russia, but so seldom nowadays in this country.—I am, sir, your obedient servant,
January 13.

M. R. L.

SIR,—While Mr. Hicks appears desirous of placing certain "facts about tea" before the public in his letter to you of the 6th instant, he has omitted to record other facts which may interest and enlighten your readers. He says that "all good tea is, when infused, of a bright copper colour in the leaf"; this characteristic, however, which is indicative of faultless manufacture, must not be looked for by the consumer unless he pays a fair price. A tea with a bright copper coloured leaf after infusion cannot be got first hand under eight pence to nine pence per pound (ex-duty four pence), and such tea if sold in its purity will not be offered to the public under 1s 8d to 1s 10d per pound; but it must be remembered that a consider-

able portion of this margin has been swallowed up by the various middlemen who intervene between the grower and consumer. Then, again, in comparing one tea with another, the consumer invariably overlooks the fact that he buys by weight and uses by measure. The trader is alive to this fact, and scarcely any, if any of the best Pekoe Sonchong and Pekoes reach the consumer as imported. The leaf is passed through a mill, which reduces the original size to any desired degree, and it can readily be understood that after this process a much greater quantity can be taken from the caddy with the traditional caddy spoon than would otherwise be possible—in other words, the milling process increases the specific gravity, and the consumer is unwittingly using a greater weight of tea than if he purchased an "hoarse tea"—i.e., that which has not been tamped with.

The comparative strength of tea can only be determined by weighing equal quantities, and infusing them an equal given time in the same quantity of water, as practised by experts. By measure a tea sold at 1s 6d which has been milled to half its natural size can be shown to be better than another which has not been milled, at 2s per pound, as judged by the strength of infusion, simply because a greater weight of the former has been used. Of course, milling the leaf will not affect the flavour of any tea, whether it be Chi'a, Ceylon, Darjeeling or Assam. So far as Ceylon tea is concerned, I rejoice to see that it has made much rapid strides during the last few years; but it is a curious fact that, although grown almost wholly from Assam Valley indigenous and hybrid seeds, it has assumed the characteristics of the best Chinese tea, due to soil and altitude, its superiority to China being due as in India, to its cultivation being superintended by Europeans, and the best approved machinery, whereby the leaf is only touched by hand in picking it from the bush, all subsequent processes being achieved by machinery as opposed to manufacture wholly by hand, which in addition to being ineffective, is the reverse of cleanly. Ceylon teas stand out as a class tea in common with Darjeeling, Nilgherry and Kangra Valley tea, and by reason of their flavour and delicacy appeal to the classes who consume but a small quantity. Assam and Cachar teas being full of body, and astringent, appeal to the masses who are they tea-drinkers and the tea-growers' friends. Statistical show that while Ceylon tea has gone up in consumption to the detriment of John Ombinau, Indian growths have also made a sure and steady advance for 30 years past. The immediate danger to Ceylon tea and India is the ever increasing out-turn and no expansion of markets, the result being a yearly fall in prices. From a market report before me I find that in 1888 Ceylon tea as sold in Mincing-lung averaged 114d.; for 1889 the average was 114d.; for 1890, 11d.; and for 1891, 10d. per pound. Indian teas also show a falling off, but not in such a marked degree. I travelled through Ceylon during the past summer, and cannot at all agree with Mr. Hicks in his concluding paragraph wherein he says that Ceylon tea is grown on virgin soil; almost all the tea there is being produced on defunct coffee plantations, and where coffee still exists tea is being interlined, only waiting for the death of the coffee to assert itself; and it is sheer nonsense for Mr. Hicks to assert that Ceylon tea has "beaten out of the field . . . the heavier and more luscious Indian tea," but of its class, I am quite prepared to admit that Ceylon does produce a good tea as any other part of the East.

The fact of a packet bearing the words "Packed in Ceylon" is no guarantee of its purity, nor does it carry any guarantee that such is actually the case. There are far more packets of Ceylon tea "packed in Ceylon" in the neighbourhood of Great Tower-street than ever are packed in the island, and since the duty on imported tea there is 25 cents per pound, the chances of adulteration are very remote, as the pure article can be produced at a less cost. I must apologise for the length of this, and having no desire to use your columns for an advertisement, I enclose my card, and subscribe myself,
A TEA PLANTER,
January 15th.

INDIAN GUTTA PERCHA.

The Pauchotee tree, *Dichopsis Elliptica*, grows plentifully in the Wynnad and yields an abundance of milk, and some of the planters have been asking for information on the subject and enquiring whether it could be made into a commercial article. The milk has been known for some years to afford what was called Indian Gutta Percha or Palm Gum, and has been used as an adulterant of Singapore Gutta. General Cullen brought it to notice about thirty-five years ago and Dr. Cleghorn when Conservator of Forests wrote an interesting memorandum on the subject. It was reported upon by experts in London who found that it was unfit for water-proofing purposes as its solution in coal tar and turpentine dry up to such a brittle consistence that the fabric is quite useless. Mr. Hooper, the Government Quinologist, says, "it could be used as a hirdlime or cement, and keeps well under water, as a cable insulator, especially if mixed with some gonnine gutta and that by boiling the milk of the Pauchotee tree, a white mass separates, which can be kneaded by the fingers, but which becomes hard and brittle by the cold." The brittle character of this substance Mr. Hooper says "is due to a large proportion of a crystalline substance found in the true gutta and called crystalban, or alban. Crystalban, according to Payne, occurs to the extent of from 13 to 19 per cent. in the best of gutta percha, but I have extracted as much as 60.2 per cent. of crystalban from the secretion obtained from the Wynnad. The presence of a large quantity of crystals in this gum of course, would interfere with its utility but crystalban is easily removed by boiling alcohol, and the residue consists of a very good and pure "Gutta Percha." Mr. Hooper adds that he cannot see why this process could not be used to purify the Indian Gutta Percha and so obtain an article similar to the Malayan gum."—*South of India Observer*, Jan. 23.

INDIAN GOVERNMENT QUININE.

The report for the year ending March 31st, 1891, of the Government cinchona plantations in India* has just been published, and we gather from it that the Naduvattam quinine-factory has emerged successfully from the most critical period of its existence, though it has been by no means exempt from the nasal trials of infancy. In the spring of 1890 all work was temporarily suspended, owing to an outbreak among the workmen of an influenza epidemic, an affliction which one would hardly look for in a quinine-factory. Then it was found that part of the new plant erected in the works was in such a bad condition that it was necessary almost to remake it before it could be used, a circumstance which seems to prove that the curse of scamped work, so rife among certain Government departments at home, is not unknown in India. After these difficulties had been surmounted a good part of the year was gone, and in the meantime the stock of bark in the Government warehouses had become so large as to cause serious inconvenience. Then came another adversity. The Government had made a contract in Hamburg for the supply of 20,000 lb. of fusel oil for the works, and by some means or other the shipment of this requisite was inexplicably delayed for many months. Similar delays occurred in the supply of caustic soda and sulphuric acid, and, by the end of June, the barecoal and filtering-paper alone of all the requisites ordered had been received at Naduvattam. When the fusel oil began to arrive, at last, it was found to be packed in drums instead of casks, a needless outlay of over 40% being thereby caused upon the first shipment alone. After long waiting, caustic soda and sulphuric acid had to be purchased in India at a cost much exceeding that which would have been incurred had the responsible individuals, wherever they were, been more alive to their duties. "A private firm in Madras," says Mr. Lawson, complainingly, "would have obtained the goods within four months of their writing for them"—

* Southern India.—Ed. T. A.

good a commentary as can be made upon the inability of our State departments, as now constituted, to compete against private enterprise. However, even official delay comes to an end; and in the second half of the year the factory was fairly started. Its present capacity, calculated upon the basis of uninterrupted work, is 4,000 lb. of sulphate of quinine per annum; but the total output for the financial year ending March 31 last only amounted to 2,923 lb. in addition to 1,050 lb. of febrifuge. It is now proposed to increase the capacities of the factory, experience having shown that the possibilities of increased consumption of quinine among the poorer classes of natives are practically unlimited. The present output could be almost doubled by a slight extension of the vats and steam-pans. Many improvements in the plant have already been effected, and everything is ready to increase the usefulness of the factory as soon as the necessary funds are conceded by the Indian Government. The grinding room has been separated from the boiling and crystallising room. The macerating vats and stills have been lodged in a separate building, and a second drying-room has been erected, which is heated by steam. A second boiler for heating the stills was also purchased during the year. A well has been sunk and a reservoir put up. The Naduvattam quinine is sold exclusively in India. In July last the first quarterly supply of 200 lb. was forwarded to the Medical Stores Department in Colombo, the superintendent of which expressed himself in no flattering manner about the drug. "The appearance of the quinine," he said, "is very much against it, and I hope that future supplies will be better crystallised. Unless this point is attended to, it can never compete with Howards & Sons' or other well-known quinine." These candid observations were rather hard upon the Naduvattam people, especially as they had evidence to show that the quality of their quinine was excellent so far as freedom from impurity was concerned. They explained to their Ceylon critic that the crystallisation was really very good and the bad appearance due to the drug having been partially dried by pressure instead of by absorption in consequence of which the crystals had been broken. Since then the process which gave rise to the criticism has been abandoned, and the quinine supplied leaves no further room for criticism. Mr. David Hooper is now at work upon the acid sulphate process used in Holland and Germany, and by means of which, upon second crystallisation, nearly the whole of the cinchonidine is eliminated from the quinine. Particulars of Mr. Hooper's investigations are not given, but they seem to have been satisfactory, for we are told that the process will probably before long be adopted when working upon red and hybrid cinchonas.

The greater part of the quinine produced at Naduvattam is supplied to the Government medical stores in Madras, Bombay and Colombo; but we gather that it is hoped that in coming years the factory will find its principal outlet among the natives, to whom it has lately commenced to supply the drug in 5-grain powders through the medium of certain petty local officials. Packets containing 100 such powders are supplied to these officials at 1 rupee 8 annas each. They retail the powders at 3 pies each, and have a selling commission of 1 anna per packet for themselves. Of the nine officials to whom supplies were sent by way of experiment two disposed of the whole lot, and earned from 3% to 4% commission each. Several others have shown great apathy, but they are being stirred into activity; and it is hoped that the villagers will gradually be brought to appreciate the boon which the Indian Government are extending to them, and which was the underlying consideration which led to the establishment of the Indian Government cinchona plantation and of the Naduvattam factory. But it seems that, at present, the native appreciation of the 3-pie packets is interfered with somewhat by the fact that the natives, by walking to the nearest town dispensary, and appealing there *in forma pauperis*, can get a quinine powder gratuitously. The walk to town is often a long one, and the native is naturally indolent; but coppers, on

the other hand, are scarce, and economical conditions generally triumph.

A great increase in the sale of quinine might be looked for, it is believed, if it were given in a form less objectionable to the palate than that of a powder. Might not this difficulty be overcome by compressing the drug into easily-swallowed tablets? Another step in the direction of supplying a cheap drug for native consumption has recently been taken by deciding upon the distribution, at cost price, of purgative powders, composed of quinine and of jalap grown in the Indian Government gardens.—*Chemist and Druggist*

TALGASWELA TEA COMPANY.

The following is the Directors' Report for the year ending December 31st, 1891:—

The Directors have pleasure in placing before the Shareholders their Fourth Annual Report, together with a duly audited statement of the Company's affairs and financial position as on 31st December, 1891.

During the past year the Company's property has been visited twice by Mr. E. S. Grigson, in the absence of the Managing Director. Mr. Grigson's first Report upon the property, a very full one, was printed and circulated amongst the shareholders. His second Report was read at the extraordinary General Meeting held on December 29th, 1891.

Mr. W. Agar became disqualified to act as a Director and resigned his seat at the board Mr. Loos having left the Island, and resigned his seat, Mr. VanOuylenburg was elected a Director in his place.

In consequence of the larger acreage of tea planted on Talgaswela than was originally intended, 681 acres instead of 500 acres of the immediate necessity for steam power which was not originally contemplated, and of the increased factory expenditure necessitated by the larger acreage, a debit balance of R13,519'16 remained at the close of the year 1891. A further expenditure on factory and machinery has also to be faced during 1892. Realising that to charge all this capital expenditure against present revenues was to postpone unduly the payment of dividends to the shareholders, the Directors called an extraordinary general meeting on December 29th to submit a proposal for raising the necessary extra capital (R30,000) by the issue of 7 per cent preference shares of R100 each. The proposal was carried unanimously and its confirmation will be asked for at a special meeting immediately following the annual general meeting on February 23rd next.

The Managing Director's estimate for 1892 shows an expenditure of R46,616'80, estimated crop 180,000 lb. At a price of 40 cents, a little over R25,000 profit will be realised. This should allow for a dividend of ten per cent after paying interest on the preference shares. Should it be possible to do so, the Directors will recommend the payment of an ad-interim dividend during the year.

The slow rate at which the construction of the Railway Extension to Ambalanga has been proceeded with has caused general dissatisfaction.

Messrs. T. W. Hall and H. Van Ouylenburg retire from the Directorate by rotation and offer themselves for re-election.

COFFEE ADULTERATION: A CRUEL FRAUD UPON THE POOR.

TO THE EDITOR OF THE ROSSENDALE DIVISION GAZETTE.
Sir,—I have read with equal pleasure Sir Thomas Brooks' address to his constituents in the valley and his speech at Rawtonstall last evening, when as the Unionist candidate, he opened their re-election campaign in a very decided manner. Coming to the subjects mentioned in his address, he referred, I was glad to see, in the first place, to "temperance." In the coming general election hundreds of speeches will be delivered to the electors of the United Kingdom on the same subject by scores of candidates for their suffrages, and rightly so too, for it is distinctly a very pressing question, much more so than that of Home Rule for Ireland, and one that will not brook of any

further delay. This is now admitted by the leaders of both parties.

I now come to the subject matter of this letter, and in order to do so as briefly as possible, will feel obliged by your giving publicity to the following extracts from letters which have lately reached me, viz:—

From the Secretary of the London Chamber of Commerce.

"I am fairly conversant with the question of coffee mixtures. Messrs. —, one of the largest distributing firms in the heart of London, and who confess to the introduction of 75 and 85 per cent. of chicory in their tins without the slightest intimation to consumers as to the extent of the adulteration, have, for years, declined to sell coffee mixtures at all, and have only given way lately owing to the pressure—if not the necessity—of supplying the demand for them, as the trade generally continues to sell them in tins as mixtures only. As regards the purity question you are right in assuming that this Chamber was interested in the matter, and some years ago, when Mr. Gladstone's Bill, to which you refer was passed, we did all we could in Parliament to get the exact proportions of the different ingredients indicated on the labels.—The president of the Chamber, at that time, Mr. Mingiac, M.P., brought in an amendment to this effect, but the Grocery interest which preferred that no indication should be given was too strong for us and we had to accept the compromise contained in the Act as it now stands. I will, however, consult the commercial legislative committee of the chamber with the view of considering whether sufficient time has elapsed to move for an amendment of the old Act."

From Alfred W. Stokes, F. C. S., F. I. C., Public Analyst for Paddington and other London Parishes.—December 23rd, 1891.

"I entirely agree with you as to the idiocy of the present exemption (practically) of coffee (?) from the Adulteration Act. I have tried to bring public opinion to bear on the matter, but it is only from outside pressure that we can hope to have the law altered.—Again, under date 5th January, 1892, Dr. Stokes wrote to me as follows:—"I could not send you the particular report referred to by the *Standard*,—vide the leading article on coffee adulteration in that paper under date 12th November, 1891, because I had not one left. I sent you, however, another that covered the same ground. In my opinion there are a great number of people who have never had the chance of tasting pure coffee, so universal is the adulteration. I am very very pleased to see the vigorous way you are trying to rouse the public conscience in the matter.

Would that I could rouse the conscience of Mr. W. E. Gladstone, for he it was who under pressure of the Grocers' vote, not only gave them licenses to sell intoxicating liquor, but at the same time under the Coffee Adulteration Act, 38 and 39 Vict., c. 63, permitted free license to Grocers to adulterate coffee to any extent, even to 99 per cent of chicory if the presence of one per cent of coffee could be proved, provided the vile compound was labelled simply "coffee mixture" and "sold as a mixture of coffee and chicory" on alternate sides of the tins or packets. Moreover even although "Coffee" should be asked for, and a tin of this vile mixture be proffered the public analyst is under this truly vicious law, unable to exact any penalty whatever, the magistrates ruling that the words printed on the tins were under the Act, a "sufficient defence." Vide *Standard*, November 12th, 1891. I cannot better describe this truly shocking state of things than by quoting some of Mr. W. E. Gladstone's own words in his last speech in London before departing for Biarritz:—

"I indicate it with feelings of pain, of recoil, almost of horror—no word short of horrible is fit to describe it. We have to blush for such a state of things. We must let every man know what is and what is not an offence by clear enumeration. I look forward to the issue with cheerful faith when the population may sit down under the shadow of beneficent legislation, and with confidence to the Legislature to live and die in contentment and in peace."

These bo grand words, my Rossendale friends, which, when you weigh them up and analyse them thoroughly you will find they much resemble a "coffee" (?) mixture containing 85 per cent of chicory. Valn is the snare set in the sight of any bird. Do what I will, I cannot rouse up Sir Wilfred Lawson on this chicory question—nor do I find any response from the leaders of any of the great temperance leaguers—either church or secular. Peradventure they are all asleep and must be awakened. The press too, seems almost culpably indifferent to the question. Is it because the grocery interest is so very strong in this country that editors are afraid of meddling with it? Out and out cases of poisoning, &c., &c., or of some dreadful scandal have a free run of the press but a case such as I have produced surely merits equal publicity. Certainly everyone is entitled to know to what extent they are being robbed, and if the sale of "coffee mixtures" should, under a new Act of Parliament, still be legalized, they should bear in unmistakable type and figures a true "Enumeration" as to their contents. Chambers's Encyclopædia has the following on "chicory."—"It has a long carrot like root of a dirty or brownish yellow colour—it grows in waysides, borders of fields, &c.—it contains a good deal of sugar, but otherwise does not serve to supply the animal economy with any useful ingredients. It gives off a dark brown colour to water, when an infusion made, and hence its main use in coffee."—"Oak-bark tan, logwood and mahogany dust, and even the livers of horses and bullocks, are said to be employed in its adulteration." What "adulterated chicory" may cost per pound I know not, but the finest "Bruges" chicory is worth, wholesale, in London, about 38s per cwt., or about 3½d per pound.

Need I say more? I have already tro-passed somewhat severely upon your space, but the subject is surely deserving of it. Lancashire people are known to be the hardest working people in the whole world, but if they are to give up taking unadulterated beer, for heaven's sake let their "non-intoxicating beverages" be equally pure and above all suspicion. Tea is now credited with being positively pure, but what says the editor of the *Produce Markets' Review*, on December 19th, 1891, under heading "Tea."—"It would be better if many of these very objectionable parcels were stopped by the Customs from being offered for home consumption." Here is work to "nudo" for the Gladstonians, and "work to do" for Sir Wilfred Lawson and all
TRISTOTALERS.

5th January, 1891.

P.S.—The Secretary of the London Chamber of Commerce, in his letter quoted above, refers to their acceptance of a "compromise"—whatever could be the "original" bill have been like? if I remember correctly, Mr. Gladstone promised a "fair field" to both coffee and tea—under pressure. Parliamentary history records how, oratically speaking, he, at the last moment almost, threw the bill to the wolves! Last year, the Emperor of Germany kicked out of his empire every bogus coffee bean making machine and every bogus coffee bean.

PLANTING IN JAVA.

Mr. G. P. Hill writes from Ayer Dingin, Karé-saan, Java, 21st Jan.—

Here we have just (Oct. 1891) polished off a 6,000 odd piculs (clean) crop and looking forward to 5,000 piculs this season. Size of estate 300 hours say 800 acres about. Last dry season lasted six months which seems to suit the coffee trees. At any rate at this elevation 1,000 to 3,000 ft.

Coffee is here grown under shade. The dadap is preferred but for some years past we have had our trees killed by some unknown disease. The only other kinds of shade trees used in Java are the *Albizia moluccana* or Sengon (*Albizia stipitata*) rather much liked the A. M. especially on account of its being very brittle, (and some other sins). We are trying *Ficus glomerata* and *Grevillea robusta*

both strongly recommended by Mr. J. P. Hunt in a letter to the *T. A.* in Nov. 1889.

After considerable time and some correspondence the seeds were got from Colombo. The silk cark (G. R.) is quite unknown this end of the island, and the knowing ones object to the *Ficus glomerata* because it belongs to a bad tribe, they say, the *Ficus* family being surface feeders, viz., throwing up numerous rootlets along the surface of the soil, eating up all moisture and "humus." However, the *F. glomerata* is also a stranger here.

Most of your space in the *Tropical Agriculturist* i (very naturally) taken up with tea. I think, however coffee should not be forgotten, and if you could put me in the way of learning more about the *Ficus glomerata* and other kinds of shade trees, I should be much obliged.

[*Ficus glomerata* is a favourite shade tree for coffee in India, and of *Grevillea robusta* they say in some parts of Southern India that this beautiful and valuable tree is actually a remedy for leaf disease. The masses of leaves deposited must have a fertilizing effect.—ED. T. A.]

INDIAN TEA DISTRICTS ASSOCIATION AND TEA FREIGHTS.

A meeting, which was largely attended, of the Association was held on Tuesday to consider the question of ocean freights. The Chairman (Mr. R. B. Major) detailed the negotiations that had taken place between the sub-committee and the representatives in London of the steamer companies that run on the Brahmaputra stating that the latter had assented in great measure to the proposals of the sub-committee in relation to a further agreement for a period of five years, and had accepted some of the modifications with the committee considered fair in the schedule of rates. The committee had heard, however, with some surprise that the steamer companies, ignoring the negotiations with the sub-committee, had been offering to the members of the Association individually a form of agreement in which nearly all matters were decided in their own interest, asking them to bid themselves to the companies for a period of seven years (or nearly a lifetime). He was glad to find that this step had not met with much success, and he hoped that members would refrain from accepting any form of agreement other than that approved by the committee. He thought that the committee had just grounds of complaint against the steamer companies for lack of straightforwardness in the matter. Resolutions pledging the meeting to uphold the action of the sub-committee were unanimously passed.—*H. and C. Mail*, Jan. 22.

PLANTING IN MALAY STATES.

Mr. Watson at Bentong has planted about twenty acres of land with Liberian coffee, and the experiment would appear to give the greatest promise. With this exception, however, very little, or nothing has been effected by European planters with a view to testing the resources of the country for agricultural enterprise. Little doubt can exist, however as to the fertility of the soil, and from the few facts in our possession there would seem to be every reason to believe that planting might be successfully carried on in the State, if labour could be obtained in sufficient quantities at reasonable rates of wage. The Pahang Exploration and Development Company has erected saw mills, and has done substantial work at Kuala Lumpur. The company has not, however, been altogether successful in its arrangements with native wood cutters, and frequent misunderstandings as to prices, measurements, &c., have caused the Malays to lose confidence and to be reluctant to work for the company. This difficulty will no doubt be eventually overcome, and as the property

is undoubtedly a fine one—the enterprise should end by proving successful.—*Acting British Resident at Pahang, March 31st 1891.*

If the Malay Peninsula is ever to be a great coffee-growing and exporting country, the importation of labourers under contract from India is a necessity, and if a great forward movement in agriculture could be reckoned on, the Government should do what is possible to facilitate and cheapen immigration. But at present the number of planters and of estates is very small and as long as a few hundred men are all that they can absorb, the question is not an urgent one. It is easy to allege that capitalists are deterred from embarking in agriculture because of the difficulty in obtaining and keeping a labour force, but general statements of this sort must not be accepted. If planters in sufficient numbers were to start operations in Selangor, the labour question would soon simplify itself. To make elaborate preparations to provide labour for agricultural purposes when the employer is as yet an absent quantity is somewhat premature. In the meantime, the alleged scarcity of labour will continue to furnish to land speculators an excuse for not opening tracts of forest land obtained on easy terms from Government ostensibly for agricultural purposes.—*British Resident at Selangor, March 31, 1891.*

NOTES ON PRODUCE AND FINANCE.

THE TEA TRADE OF CHINA.—Col. Howard Vincent writes in reference to his remarks, which we quoted last week, some of which have been challenged, about the decay of the China tea trade:—"I am not surprised that some of the statements of fact in my recent articles have been challenged, as they are contrary to beliefs sedulously fostered at home. It is not necessary for me, I hope, to say that they were not expressed on the authority of my brief sojourn in China, but entirely from official data, supported by the personal views of the experienced residents to whose acquaintance I was admitted and tempered by a not unnoted observation. The expression 'the tea industry in China is threatened with extinction' to which 'A Tea Broker' takes exception, was borrowed from the report of a very old-established firm. It applies, of course, particularly to the tea trade with England. Your correspondent, moreover, himself endorses it in the sentence 'I am of opinion that the present China tea gardens are exhausted. To remedy this state of affairs the efforts of the Inspector-General of Maritime Customs must be supported by the united strength of all persons interested. They are not at present, I am informed on good authority, even associated together.'

TEA FREIGHTS.—This question was discussed at a recent meeting of the Indian Tea Districts' Association; and it is evident, from the remarks of the chairman, Mr. Magor, that the steamer companies have made an effort to get at the planter individually, rather than tackle him in conclave, as they should have done. If the planter be wise, he will decline to discuss the matter in his individual capacity, but will refer all negotiations to those who represent the general body of planters. That union is strength is an old maxim; but it is as true today as it has ever been.

CEYLON TEA.—Referring to last week's sales of Ceylon tea, the *Produce Markets' Review* says:—"One of the largest sales of Ceylon teas on record has been held this week, but prices have, notwithstanding, been wonderfully well-maintained. In the case of fine parcels both of Pekoes and broken teas, competition has been particularly keen, and higher prices have in many cases been paid; for medium grades also the position has been favourable for sellers" but common sorts show a distinct decline, and these are now at low rates they were during November. The quality of

the teas now coming forward is still considerably below what it should be, and it seems highly probable from present indications that the old excellent standards of quality of two years ago will scarcely be again equalled without the liberal use of artificial manures. This subject will have to be duly considered by planters if Ceylon teas are to maintain their present position as the favourite teas of the British public. There has been no diminution in the supply of Indian teas (says the *Produce Markets' Review*), the quantity brought forward at public sale having even exceeded that of last week. Monday's auction was the largest on record, consisting of nearly 26,000 packages; but, notwithstanding the large total, the supplies meet with general support, while teas with point and quality in many cases showed an advance. As might be expected, however, some irregularity was noticeable, and lower prices had to be accepted for the common and inferior sorts. With smaller supplies coming forward a firmer market may be expected, and, as the trade have evidently been waiting the result of the late heavy sales the demand for home consumption will no doubt increase, more particularly as prices are now at a comparatively safe level.

LAST WEEK'S TEA SALES.—Says the *Grocer*:—"Boating the record" is an expression frequently used in describing the increasing extent of the supplies of Indian tea by auction, but it has never been more applicable than in the present week, during which about 49,100 packages have been submitted for public sale, involving an amount of time, labour, and fatigue in tasting and valuing the teas and pricing the catalogues such as the dealers would not relish very often, and which culminated on Thursday in a feeling of exhaustion, not unmixt with a sense of relief that the severe and continuous strain was over for another week. Competition was liveliest on Monday's sales, when the assortment was largest, and strong-flavouring kinds of favourite growths were taken at firm to rather high prices; but teas thin and poor in cup were, as a rule, avoided by the trade, and were disposable only on easier terms, which became still more so towards the end of the final series yesterday, and though the bulk of the supplies in auction has found buyers, the tone of the market at the finish was uncommonly tame, as if the wholesale men had overbought themselves and needed breathing time to work off their surplus stocks. About the largest sales yet held of Ceylon tea have taken place this week, amounting to nearly 26,000 packages. The number of samples to be examined was great, and small breaks formed a good proportion of the general total. The efforts made to curtail the trouble involved in the latter remains of little avail. Tuesday's auctions occupied the greater part of six hours. Prices, especially for common, are mostly lower. The biddings lacked a continuance of spirit, and the market closes with a flat tone. The pressure of Indian, along with the haste to sell, has quite altered the aspect of the market during the past week, and some low rates have to be recorded, the presence of low teas also helping the depression. The week's imports have comprised:—The Glenshiel, 7,100 lb.; Orion, 166,300 lb.; Orient, 397,900 lb.; Dunera, 215,500 lb.; total, 786,800 lb.—*H. and C. Mail, Jan. 22nd.*

THE AUSTRALIAN IRRIGATION COLONIES OF MESSRS. CHAFFEY BROS., LTD.

In the fifth annual report of the Victorian Minister of Water Supply, which was lately presented to both Houses of the Parliament of that colony, we find it stated that the progress of these settlements is giving striking proof that the arid waste lands of Australia can be tilled and brought to sustain those who settle on them, thereby affording what is so much needed in these days of over-stocked labour markets and congested centres of populations—greater scope and more opportunity for working capacity. It is, by its example and teaching, assisting to develop a comparatively new but most important industry, by which the resources of the colony will be greatly increased, and it demonstrating to the farmers and fruit-growers of

the country what irrigation properly employed can accomplish, and how best to make use of it. The progress that has been achieved is, without doubt, largely due to the liberal manner in which the Messrs. Chaffey have interpreted their obligations. According to the agreement with the Victorian Government, under which the Messrs. Chaffey entered upon the occupation of the present area, they were bound to expend on the land the sum of 35,000*l* during the first five years. There has actually been expended up to the 30th June 1891, 275,000*l*, though the colony was not four years old until October, 1891. In addition to that it is estimated that the settlers themselves have spent, in improving their land, 100,000*l*. The population has increased to about 3,000 and continues to increase. Fully 6,500 acres are already cultivated, about 6,000 acres being devoted to vines or fruit trees, the remainder being under feeding stuffs such as sorghum and lucerne or cereals.

The foundation stone of the projected Agricultural College in the colonies was laid by His Excellency the Governor in April, 1890, on a prominent site in the principal thoroughfare—Deakin Avenue. Its erection is being pushed on, the contract for one wing having been let at 5,000*l*. The importance of this institution—fully endowed as it is, one-fifteenth of the entire value of the land having been set aside for that purpose—not only to Mildura, but to Victoria cannot be over-estimated.

There are now constructed 125 miles of main channel and 200 miles of subsidiary channels; 50 miles of various channels are surveyed, and, as the surveying parties are pushing beyond the 25,000 acre limit, are being daily extended. The engineering works and the foundry have been greatly enlarged, and afford occupation for a large staff in these works and the other work of the settlement. The company's pay-sheet shows a disbursement of 7000*l*. per month. Every possible fruit has been found to flourish amazingly, with the exception of apples, but Mildura oranges will yet become a feature. The early and large returns which have been obtained are due not alone to the quality of the soil or the character of the atmosphere and climate, though these aid, but also to the methods of irrigation and cultivation practised and advocated by the Messrs. Chaffey through their staff of experts.

Mildura is a veritable *urbis in rure*. On the one hand, its salubrious climate—its proportionate desirability is the smallest in the world—picturesque situation on the banks of a noble river, its surroundings of fresh green orchards and rolling meadows, give it all the attraction of a pleasant country village. On the other hand, the nature of the society, the close manner in which the land is settled (rendering possibilities of social intercourse as easy as in town), the institutes, libraries, museums, and the various societies—horticultural, settler, etc.; and clubs—tennis, football, rowing, dramatic, debating, pedestrians—add to it the convenience and social characteristics of city life, and make up a most desirable and attractive condition of life.

From recent reports in the leading Australian papers we learn that, at the half-yearly meeting held in Melbourne of the shareholders in Chaffey Bros., Ltd., Mr. Levison, M.L.A., Chairman of the directors, presiding, the statement of accounts showed that the profits for the half-year, together with the balance brought forward, amounted to 39,153*l* 1*s* 9*d*. The chairman, in moving the adoption of the financial statement, said that the directors had pleasure in being able again to furnish a most encouraging record of the progress of both their colonies. The area of land sold had been greater than in any previous like period, and the population had been considerably added to by an exceptionally good class of settlers. The fame of their young but great colonies was attracting much attention in the United Kingdom as an eligible field for capital and enterprise, and a goodly number of settlers and investors were arriving from abroad. The trade and commerce of both colonies were assuming large proportions, and two additional steamers had been put on the river from Swan Hill and Mergau. Buildings both for

residential and business purposes were being largely multiplied, and the substantial character of the new structures afforded perhaps the strongest evidence of the confidence felt in the future development of the resources of the settlements. Efforts were being made to push on the surveys as rapidly as possible. Additional town sites were being surveyed to meet the requirements of new settlers, and two or three villages or minor townships were being surveyed meet suitable localities. Leviathan pumping plant at Psyche Bend, one of the most powerful in the world, was being erected, and would soon be completed and at work. Main channels had been extended some twelve miles, and the subsidiary channels about forty miles; the channeling now completed commanded some 30,000 acres. The several industries established by the company were in a satisfactory condition, and the making of the water pipes from paper, an industry quite new to the colonies, had been started and was in active work. The employment of open flumes was giving place to the more economic method of distributing water by this new process. The steam brick works were being rearranged, and the manufacture of porous fire-bricks or terracotta lumber, the local demand for which was considerable, had been added. The plantations appeared healthy and free from blight and insect pest, and the public health was excellent. Altogether the condition and development of the colonies left nothing to be desired. His excellency lauded the shareholders upon the excellent balance-sheet and the result of the Company's business for the past half-year. The subscribed capital had been increased by 42,780*l*., brought about by the sale of 4278 shares at par, upon which the sum of 7250*l*. had been paid. The net profits for the half year amounted to 23,032*l* 3*s*. 9*d*., or equivalent to 12 per cent. upon the paid up capital which now stood at 455,662*l* 1*9s*. 3*d*.. The directors proposed to place the sum of 25,000*l*. to the reserve fund, increasing it to 115,000*l*. This quantity of land sold during the half-year was 2759 acres at Mildura, and 445 acres at Renmark.—*British Trade Journal*.

NEW OPENINGS IN NEW GUINEA.

AN INTERVIEW WITH SIR WILLIAM MACGREGOR,

K. C. M. G.

One of the ablest and most energetic men in the service of the British Empire at this moment is undoubtedly Sir William Macgregor, the Administrator of British New Guinea. His official title of Administrator gives, however, very little idea of his multifarious activities. During the past four years he has explored and mapped the greater part of the territory, reconciled savage tribes, enriched the scientific world by his observations, and laid the foundation of a good Government in that vast island in the Southern Seas. He is also an intrepid mountaineer, and in 1889, with less than six followers, he reached the summit of the Stanley Mountain, the highest point attained being 13,121 feet. A previous expedition, led by Mr. Guthbertson, and assisted by 200 natives, only reached 8,000 feet. Sir William Macgregor has recently boon on a visit to Queensland, and our Brisbane correspondent sends us the following account of an interview on behalf of the *Pull Mall Gazette* :—

SIR WILLIAM "AT HOME."

Imagine a big man, over 6 feet high, with a sweet brown face, a low, gentle voice, with a Scotch accent; a man of great attainments, who speaks fluently three or four European languages, and about twenty Papuan dialects. "I have been with him," said the Hon. Hatton Richards, his late private secretary, to me the other day at the Queensland Club, "when our lives were in imminent danger: nothing saved us but the noble self-possession and supreme courage of Sir William." The seat of the Government and Government House

are in Port Moresby, but Sir William lives in the open air, or sleeps in a boat or under a "fly" tent in the islands of New Guinea. He is a man of great physical endurance; he resists all the fogs and fevers of that uncivilized land, and is daunted by no danger or difficulty.

The little steam launch "Merric England," which was such a terror to the savages on the banks of the Fly River during the memorable expedition in 1890, arrived the other day in the Brisbane River, bringing Sir William and Lady Macgregor (who had gone to Cooktown to meet her husband and), the Hon. M. H. Moreton (his Excellency's private secretary), and the Hon. F. E. Lawes, Secretary for Native Affairs in New Guinea.

"Is Sir William at home?" I inquired of a bright Australian girl who answered my ring at St. Helen's, the residence of Lady Macgregor, which stands on the bank of the Bris River. "Yes, sir," and, having delivered my card, she led me into a room the appearance of which makes me feel as if I had been suddenly translated into one of the Government offices in New Guinea. Sir William sits at a table in the centre, stooping over a map of the Kiriwina group; the floor is littered with papers, and the walls are hung with maps with unpronounceable names. Lady Macgregor and her little daughter are watching Sir William making corrections in his map of those comparatively unknown islands.

NEW GUINEA AND THE NEWSPAPERS.

Sir William spoke of England's ignorance of New Guinea. "Nothing but lies! Nothing but lies! Here is a paper with a leading article on 'the terrible atrocities perpetrated by Government officials in Papua.'" And he handed me a journal which undertakes to enlighten the English people on India and colonial affairs. It had dropped across an item in the "funny column" of one of the Australian papers, and, taking the statement as gospel truth, it had written a leading article on the subject which was to the effect that Sir William and his party were shooting Black fellows in lieu of partridges in New Guinea!

A PLANTER'S PARADISE.

"But you want to know something for the *Pall Mall* about the actual state of New Guinea?"—"Exactly. Do you consider that it will ever be a good field for immigration?" "For the small planter who really means work I know of no better opening anywhere. In the Mekeo country near the middle of the coast of New Guinea, where the tribes have been living on such terms of hostility that if any one crossed from his own country into that of a neighbouring tribe he would lose his life, the only land that is available is the neutral zone between the different tribes. The small settler who is willing to go there with the intention of planting tobacco or coconuts or coffee or any other tropical product will find abundance of land in the neutral zone. Between the two tribes he will have the native labour at his hand. The native population are extremely large, and, what is more, they are born agriculturists. We wish to get the settlers there, too, to give employment to the natives, to teach them what can be done by systematic cultivation, and to introduce among them new products. But we hope the natives will be large producers in the course of time and thus create an export trade from the colony."

CHEAP LAND AND CHEAP LABOUR.

"What is the price of labour?"—"We can supply the cheapest labour in the world. Settlers in the country can obtain labour from one end to the other of New Guinea. But no natives can be taken outside the territory of the possession; so that the whole of the labour force will be

retained for the exclusive use of the settlers. The people, I think, will be good workmen, and our experience is that they abide well and honestly by their contracts. At present they obtain their living by agriculture, and many of the coast tribes are making splendid boatmen and seamen. What the planter wants is cheap land and cheap labour. These he can have in New Guinea, a country which has this grand advantage—it is never visited by hurricanes."

NO ROOM FOR THE SPECULATOR.

"And at what price would you be willing to dispose of the land?"

"The purchasing price we put on land is merely nominal, when it has attached to it conditions as to improvement. Settlers can obtain the land at 2s 6d an acre, on agreeing to carry out certain specified improvements within a reasonable time."

"Are fresh-water springs as rare there as in Australia, Sir William?"

"No, the country is well watered. In regard to rainfall, there is a great variation in different districts, so that the land would be found to be suitable for all the different kinds of cultivation. But we do not want the speculator," he added quickly; "we can alienate no large districts, because the country is well peopled by the Papuans. Hence we do not tempt the big speculator to come to New Guinea. We do not intend to unsettle the Papuan in order to settle the Europeans."

"But the country is very large."—"Yes; I should think it is—larger than England and Scotland—and the population is not less than 450,000."

FEVERS AND FLESH-POTS.

"What about the New Guinea diseases?" I said. "A young German who was running for his life from the country told me there were enough diseases in the Kaiser's territory to eat up all Germany."—"There are no diseases in the country worth speaking of, except fever. I speak only of British New Guinea. Since I went to the possession in 1888 only two deaths have occurred in the Government service—one a weakly boy, and the other a Polynesian. There have, of course, been many cases of fever."

"But there is another matter, Sir William, which perhaps more directly concerns the European. Is there not a possibility of the settler waking up one fine morning to find himself laid out as a dainty dish for his dusky neighbours?"

"Cannibalism, which was once the terrors of the trader and the adventurer in the islands," he said, "has been almost stamped out by the missionary and the Government in the country where we are offering to the European. In this backwood land (pointing to a large blank upon the map), to which we have not as yet penetrated, there may be, and there are, no doubt, man-eaters. The settler, however, need have no fear of the flesh pots of New Guinea; he is almost as safe there as in Australia."

THE FIRST MARKET.

"Where do you expect to find a market for your products?"—"In Australia, we are going to try to establish a subsidized line to connect us with Cooktown and to visit all the northern ports and the southern coast of New Guinea. The Government is itself cultivating a great many coconuts, and we have planted about 16,000 trees; we are trying to get the natives to plant largely also, so that we hope in a few years to be able to export by direct shipment to Europe such things as coconuts, coconut oil, tobacco, tea and coffee, and other tropical products; but our first market will be in Australia, until we have sufficient to justify a ship to Europe."

THE SOIL.

"What is the nature of the soil?"—"Of all possible kinds. We have alluvial soil, coral soil, volcanic soil, and soil formed by the decomposition of vegetable matter; sandy soil, surface soil, in fact, any sort of soil desired. We have granite islands and volcanic islands, areas covered with dense forests and large patches covered with long grass or weeds. The eucalyptus flourishes in portions of New Guinea, and hardwood can be found in any quantity from the Dutch boundary to the Louisiade group."

A PORTRAIT OF THE PAPUAN.

How few in Great Britain have any conception of what travelling is in a country which has never been touched by the foot of a white man! Since the island first "rose from the dark swelling flood," Nature has had mostly her own way in New Guinea. The dusky inhabitants have lived in a primitive state, tilled their gardens, drunk the milk of the coconut, caught fish in the streams, and with the spear and bow and arrow hunted for men and beasts over the wild woods and rugged mountains of Papua. They have learned to carve and to dance and to build castles in the air—supported by trees—and, standing in their frail canoes, to row with amazing agility. They have no knowledge of the art of writing, and their only attempt at drawing, so far as has been discovered, is a representation of a human figure, done in colours—red clay and charcoal—which Sir William found on a palm leaf while exploring the Fly River. Their languages, or dialects, are closely related, so it is clear that they have sprung from the same stock; they love—platonically, paternally, and fraternally—as no other people love; they believe in some districts that when the soul leaves the body it sinks "into the utter void of nothingness," in other places that it takes refuge on a remote island; and a large section holds that the spirit takes up its habitation on the tops of mountains. They believe that all spirits are bad, but they worship no gods, fear no devils, and acknowledge no Creator. They have no vehicles, consequently they have made no roads; and in trying to pierce this strange, untracked, and picturesque land the experiences of Sir William Macgregor, its pioneer and apostle, are almost as adventurous as those of John Hanning Speke in his efforts to discover the source of the Nile.

TRAVELLING IN DARK NEW GUINEA.

The preparations made for travelling are simple enough. "We prepare some tea and sugar, rice, and tinned meat, arms and ammunition, a fly and mosquito net," said Sir William. "Then we have carriers and men to cut the roads. We walk all day; horses cannot travel, and camels would be useless to us, the country is so rocky and precipitous. At night time I and my attendant lie in our little tent, and the natives sleep under the trees. We start again early in the morning. In this way we travel from day to day. When one of the party gets footsore he is left behind. A stock of medicine is always carried, with tonics for the fever-stricken. [Sir William is an M.D.] Travelling is very slow. I have travelled as little as a quarter of a mile in one day, being very hard at work to that. One of the hardest days I have ever had was in doing 1,700 ft. The scrub is sometimes excessively dense, and it is often difficult to find a passage over the rocks and precipices. We have to get our baggage across rivers. Only one bridge, I think, has been found in New Guinea." At present the natives do not give explorers much trouble, but they put signals on the trees as a warning to strangers not to approach their villages. Great difficulty is often experienced on new rapid rivers.—*Pall Mall Gazette.*

The *British North Borneo Herald* in reviewing the past year holds that the tobacco industry there has fully asserted the fact that the country can grow a quality of tobacco equal to, and even superior to that of Sumatra, and dwells upon the alleged fact that Borneo has beaten Sumatra by at least 30 per cent in prices; and that in addition Borneo tobacco is now being anxiously enquired for.—*Straits Times.*

"ALL ABOUT COFFEE" in the *Queenslander* has the following in regard to it:—

That the coffee plant has found a congenial home in Queensland has been amply demonstrated in almost all the Northern coast districts, and recently in the Buderin Mountain district, where the crops promise to be phenomenal. In the North the driest season seemed to affect the plant but little, judging by the luxuriance of its dark green foliage when that of most other plants was yellow, and by the unusually heavy crops of cherries produced. On which we have only to repeat the remark we have so frequently made: coffee will grow well in Queensland, but without cheap labour it will not pay.

MILK OF ELEPHANTS.—The following is extracted from the *Calcutta Gazette* of Thursday, 21st Nov. 1816:—

"The following advertisement appeared in a late English paper. The scheme of converting milk into pills, is not the least curious part of the nostrum. The astonishing effect of the *Milk of Elephants* has seriously attracted the attention of the medical world; by which mercury, that deleterious poison, which has swept millions of unhappy wretches to their graves, is totally superseded and abolished for ever. Mr Campbell, of the Royal College of Surgeons, No. 29, Marlborough-street, London, is appointed to conduct this medicine. The poor are cured of the most dangerous diseases for 5 shillings. The medicine is sold at 11 shilling the bottle, or in pills at 2s 9d, with directions, whereby any person may cure himself most effectually, in cases of debility, &c., &c.—To be had, if ordered from all medicine sellers throughout the Kingdom."

PADI CULTIVATION IN THE MALAY NATIVE STATES.

—The Governor of the Straits Settlements has directed a letter to the Residents of the Native States on the subject of the rice-supply of this Colony, which is published in the *Perak Government Gazette* for the information of Members of the Council of States, District Magistrates and others. It says:—

While aware that the Residents of the Native States have not by any means overlooked the importance of promoting the cultivation of padi, His Excellency is of opinion that the time has come for renewed and perhaps more sustained efforts in the same direction: and he will be glad, therefore, if the subject should engage the earnest attention of the Perak State Council.

Before, however, this is done His Excellency desires that the District Officers be called on to report as to available land and as to the steps necessary to get it opened up.

With the body of information thus obtained, taken together with the knowledge and experience of the Sultan and other Members of the State Council, His Excellency considers that it ought to be practicable to improve the existing state of affairs, and largely extend the cultivation of padi throughout the Peninsula, and I am to say that if the Government can assist in the way of getting good seed padi from places outside the Colony the necessary steps will readily be taken.

I am to add that the opportunity might be taken of considering the question of introducing the cultivation of some of those grains, such as dholl and ragi, which are in general use among the Indian population.—*Singapore Free Press.*

Correspondence.

To the Editor.

"SUBLIME TOBACCO" "QUID RIDES?"

Jan. 24th.

SIR,—No one will regret more than Ramasamy the collapse of tobacco cultivation in Ceylon, for to him the *pogonelli totum* was a veritable paradise. There he could enjoy his *otium cum dignitate* undisturbed by all influences of an intrusive and discomfoting character. His affection for the "Smokeleaf" estate was unbounded, for besides enjoying the blessings of an easy life, he was about the only party who made anything out of the concern. How very prominently Matale has lately been figuring as a burial place for many British sovereigns. First we have the Government dropping, year after year, a goodly number of rupees (equivalent to many sovereigns) on a badly fed railway. Then we have the lately revealed fiasco in connection with the Ceylon Tobacco Company. And, last of all, we have been told that the Ceylon Land and Produce Company have found it absolutely necessary to write no less than £8,038-10-8 off the value of their Matale properties! There surely must be something wrong in this, and, perhaps, Mr. Fairweather's remarks at the late meeting of the Ceylon Tobacco Company may admit of a wider application than he meant them to do. Anyhow, economy seems to be a more necessary precursor to success in Matale than in any other district in the island. Let superintendents be bound down to produce their crops at the minimum cost, and Matale may yet prove to be a safe district in which to invest the money of a sometimes over-confiding public. But, before deciding, let investors take a hesitating mental glance backward, into those abysses of financial death which have engulfed many of us, and which may be open and engulf many more. They should never fail to be guided by a wise foresight in making all preliminary arrangements, or to take soundings of the most minute and careful kind.

Tobacco growing is never likely to be repeated in Ceylon on a large scale. Anyone venturing to do so is not likely ever to be in a position to invest in the purchase of a carriage, or to print on its panels the punning motto recommended by Theodore Hook to a successful tobaccoist, viz.

QUID RIDES.

LORANTHUS AND HEMILEIA.

SIR,—In an editorial note on a letter in your issue of the 29th instant, you say that the Loranthus "spreads over the stems and branches of trees, and from the bark cells sucks out the life blood, as the mycelium of *Hemileia vastatrix* does in the case of coffee leaves." Loranthus and *Hemileia* may be both classed as parasites inasmuch as they both subsist upon a host, but there is this distinction between them, viz., Loranthus sends its roots into the wood tissue of the host and absorbs the crude sap consisting of water with substances in solution that have been taken up from the soil, not yet manufactured into organic material, the manufacturing being done by Loranthus itself as is evidenced by the fact of the latter containing chlorophyll or green colouring matter. *Hemileia*, on the other hand, absorbs the elaborated sap from the bark (or more correctly the bast) tissue: that is to say, it does no manufacturing itself at all, but robs its host of the manufactured or prepared food—and hence it needs

no green colouring matter. To express this distinction in another way:—Loranthus does not forage for itself but robs its host of its (the host's) supply of raw materials or uncooked food. *Hemileia* on the other hand waits, as it were, till the raw material is prepared, and robs its host of the "cooked" food. Thus *Hemileia* is the greater, meaner, more cunning end, withal, more dangerous thief!

And so some botanists distinguish between these two kinds of parasites as *partial* parasites (such as Loranthus) and *true* parasites (such as *Hemileia*).—Yours, &c., T.

[We are much indebted to our accomplished correspondent for this interesting note, but we are puzzled by the representation of *Hemileia* feeding on the juices of the "bast" or "bark." If so, we have learned something utterly new to us about the leaf fungus. Our impression was that the spores never penetrated the bark of the coffee bush, but entered through the stomata of the leaves, the mycelium then breaking up the cells and feeding on the elaborated juices.—En. T. A.]

FINE vs. MEDIUM PLUCKING.

DEAR SIR,—A letter by "W. A. R.," a "well-known" planter, has appeared in the local "Times" on the above "time-worn subject," (as the editor rightly calls it): and, except for the heading, which is in bad taste (*spes mea in te*), and which is supposed to contain a joke, there is absolutely nothing new in the way of information conveyed to the reader. A few figures are given, which are utterly worthless except as a multiplication sum for boys of the first standard, as they are not founded upon fact. 600 lb. per acre cost, say, so much: profit so much: 400 lb. per acre cost, say, do do do. Therefore, much better get an average of 1s for your tea if you can: Q. E. D. The fact is that the conditions under which tea is grown in Ceylon are so varying and variable, that no general law can be laid down with regard to any of the processes of cultivation and manufacture that will be applicable to the whole country, or even to neighbouring districts. What each individual planter must strive to do is to find out his own district's peculiarities of soil, climate, &c., to a T, act accordingly, and allow no rubbish to leave his factory.—Yours KAROLY FÜRDÓ.

[Our correspondent has failed to notice the main point in the letter, viz., the wonderful assertion, contrary to the opinion of all experts, that fine plucking exhausts tea bushes less than ordinary plucking!—En. T. A.]

TEA IN PERSIA.—The British Consul at Meshed (Persia), in his report on the trade of Khorassan for 1890-91, states that the Chinese tea imported was all purchased from British traders at Bombay. There being a doubt about this last year, the value of Chinese tea was excluded from the total of British imports in last report. The value of green tea imported during the year 1890-91 fell by £7,933, being only £117,781, as against £125,714 in 1889-90. But the value of black tea imported amounted, on the other hand, to £28,269, or £11,126 more than in 1889-90, when the total was £17,143. It may be noted here that all tea imported from Bombay by the Persian merchants of Yazd goes direct to Russian territory, via Sabzawár. Of the green tea about £111,016 worth was Chinese tea purchased in Bombay, against £118,571 last year. The value of Indian green tea was £6,765 worth, against £7,143 worth last year. Of black tea £23,269 worth was imported, of which £19,706 worth was Indian against £12,000 last year. Of the green tea about £98,365 worth passed on to Russian territory.—L. and C. Express, Jan. 22nd.

GARDENING BEET.

This useful salad plant luxuriates in just such a soil and situation as suits the carrot, viz., a deep and warm light sandy loam, rich and sweet, and in an open and sunny spot. The roots abstract a good deal of potash, soda, carbonic acid, and chloride of sodium (common salt) from the soil, which should therefore be rich in these principles. Hence salt, kainit (which supplies potash), nitrate of soda, and soot or any kind of charred or burnt material, are the best manures for this crop, and may be freely applied either to the soil before sowing, or after the plants are up, in the shape of a top dressing. For all ordinary purposes the first week in May is quite soon enough to sow beet; if done much before this the roots are apt to become too large and coarse. For small gardens, Dell's Crimson and Nutting's Dwarf Red are perhaps the best kinds to grow, and a new variety known as the Cheltenham Black or Green-top has lately been attracting much attention. In lifting beet take particular care to avoid breaking the roots; if any of even the smaller fibres are injured the roots bleed, and both the colour and quality suffer. The best way is to dig a deep trench, and take the roots one by one out of the flatside or wall of it.—*S. I. Observer.*

TEA.

Continuing his remarks, already quoted in the *Liverpool Mercury*, R. M. writes:—
In the strange Republic of Chili, with its Indians and Europeans, its narrow seaboard and wild plateaus, the Natives drink mate. Sitting in their windowless houses on a bleak night, with all airholes stopped up, they sing strange songs to the sound of the guitar, and the dark-eyed girls dance, castanets in hand, while the old, blue-eyed women sit and suck mate. They do not drink it as we drink tea, but they suck it through a tube like a pipe stem. A black, fire-smoked jar stands on the earthen brazier all the time, and in the intervals of the song and dance the jar is passed from hand to hand, each one using the tube in turn. The taste of the liquor is disagreeable at first, but it soon grows pleasant, for it contains the essential of tea, and all the poor people use it. The methods of imbibing mate are repulsive to us, but when we live in Rome it is best to do as the Romans do, and so we soon acquire the Chilenian habit, and take our tea under new conditions. It is this widespread yearning after tea which made the over-green plant take such a deep hold on humanity. Dharma carried the seeds of the plant to China long ago, and the Chinese cultivated it in every spare place. They did not give it the best ground; that was reserved for rice and vegetables. They planted the seeds of the over-green on hillsides, on embankments, and in places where little else would grow. The plant was hardy, and survived all its ill-treatment. It lived through hoeing and pruning and insect plagues, and became a strong defiant plant. It will grow to be a tree 30 feet in height, and a foot in diameter, if left alone. The leaves of the Chinese tea plant will expand to four inches in length, and some of the Indian tea plants grow to nine inches, but they are not allowed to develop into trees. They are set out in rows in a garden, and suffered to grow to three, four, or even five feet in height, but that is all. The flower of the tree is whitish, or aromatic, and pretty; the leaves resemble the willow, but closer is the relationship it bears to the camellia; and more of that anon. They have about 1,500 tea plants to the acre, and this produces in a year say 300 pounds of tea, though it is almost needless to add that tea gardening varies with districts, countries, and climates. The plants are dug up every twelve years, and a new seedling is planted, which is ready for picking in about four years or less, according to the conditions. The Chinese had a monopoly of tea for centuries, though our first shipments came from Java, and it was well on in the 10th century before we

ever heard of it. It will be an interesting story to tell how tea was first introduced to England, and we will come to that later.

The Indian people seemed to have forgotten all about tea, and nobody dreamed that India was the real home of the plant. It was in the year 1820 that Mr. David Scott sent some leaves from a northern province of India to the Government at Calcutta. These leaves were said to belong to the wild tea plant, and Mr. Scott wanted the Government Botanist to examine them. Now, Botanists are very clever people as a rule, but it is perfectly astonishing to find how little discernment many of them possess. Botany seems to reduce a man's mind to the smallest possible technical limits, and the few great-souled botanists only go to prove the rule. This botanist at Calcutta said the leaves were those of the camellia, the familiar ornamental flowering plant which grows so heartily in our hot houses in England today. Such faith did Mr. Scott and his allies have in the botanist, that the master was dropped out of sight. The gold mine of the tea trade was coolly passed over and forgotten, and the leaves from Kuch Behar and Rangpur were no more remembered by the wise men of Calcutta. It was in the year 1834 that another man, more determined than Mr. Scott, said that "Camellia or not, these are tea leaves," and then began a new era. The leaves of the tree were indeed those of the over-green, which had filled China with the wealth of Europe. It was discovered that in the deep, pathless, tiger-hunted, fever-cursed jungles of Assam, the tea tree grew wild. We never saw wheat grow wild, the Chinese never saw tea grow wild; but here, in the poisonous jungle, the tea plant was growing wild. It was a startling discovery, for Nature seldom makes a mistake. If the tree had been an alien it would not have flourished so through long centuries, unknown and uncared for in this Burmese jungle. Men were sent to China to seek out the implements and the gardeners for the cultivation of this indigenous tea plant, and the work was begun in England's mighty colony. The tea fever seized the people just as the gold fever has taken hold of other races, and everybody who could raise money or interest went into the trade. In 1835 a pound of tea was sent to England from the indigenous leaves of the Assam tea plant. In 1840 the great Assam Tea Company was formed, and the trade has gone on ever since with strange fluctuations. Indian tea was better than Chinese tea, but English palates had grown accustomed to the flavour of the Celestials' plant, and a new taste had to be acquired. We reject tea which is much superior to what we have been in the habit of drinking, simply because it is strange to our taste. Then, too, the tea planters, in their haste to grow rich, forgot the old laws of Leviticus, which are founded in adamant. The "shalt not" of the law-giver was rooted deep in Nature's heart. The growers went into the moist depths of the hitherto untrodden jungle, and brought forth the seeds of the tea plant, and set them in well-prepared gardens. But the new conditions were not favourable to the moisture-loving plants of the jungle, and the evergreen became delicate and difficult to rear. Fortunes were lost in the undertakings of foolish people who dreamt not of the undying nature of law. Fire burns, water drowns; and no policemen are ever required to see that they obey the law. "Thou shalt not," if based on truth, is eternal. The Indian tea was a failure until the wise men saw what was needed. The Indian plant could not succeed on the broad garden lands of Assam, because the jungle had been swept away. The Chinese plant had contrived, through long centuries, to live under hard conditions, and now it was brought back to its ancestral home. To live under the new conditions, would soon have told injuriously on the hardy Chinese tree, for it was not used to be coddled and cared for in an equable climate; but it learned how to share its rugged hardness with its Indian kinsmen, and the result was wonderful. The Assam tree, the indigenous plant, was hard to rear; but it was strangely good. The Chinese relation was strong and wiry and easy to rear, and the hybrid product of the two made

a healthy and tasteful plant. The deep valley of Assam, where a mighty river flooded through trackless jungles, became a smiling garden, where hundreds of Europeans and thousands of Nativos lived and worked constantly through the years, and the tea plant blossomed abundantly. Year by year the cultivation spread, until it reached even to Ceylon. The Coffee planters in that beautiful island looked on in amazement, and saw the tea trade coming from China to India. Then, in 1876, there came a failure of the coffee crop, and Ceylon figured in the market with its tea.

Now come two or three hard facts. In the midst of the struggles of the Indian plant to get a hold in our market, the Chinese methods of adulteration reached a maximum. Some of the methods adopted were simply poisonous, and others were startling from their very audacity. One sample analysed in London gave the results of 40 per cent. of iron filings and 19 per cent. of silica. The adulterations were truly shocking and the Customs authorities found power to examine all imports and to control such things within what might be called reasonable limits. Then the planters of India went to work on a scientific basis, and raised good tea, sending the unadulterated leaves to our market. But Englishmen are slow to change. Habits once acquired grow to the tenacity of religious beliefs, and the adulterated China products held their own in our market for many a day. Then came the wise men who saw what was required.

It is amusing to note the manner in which Indian tea has stolen in on us, in spite of ourselves. Take Liverpool as an example. A shrewd man saw that the Chinese tea could be "blended" with Indian tea, to make a pleasant beverage. He taught the grocers how to do it, and a revolution was effected—or is being effected—on purely evolutionary methods. The public liked the new blend well, for the Indian teas are strong, and the Chinese teas are weak, and an ounce of Indian tea will make almost as much good liquor as two ounces of Chinese tea, and so the grocers found it to their advantage to use the new imports. Slowly we change; slowly the planters change; slowly the trade changes. But all is changing. The Indian tea gardeners are using hybrid plants, crosses, between Indian and Chinese. English people are drinking hybrid teas, and we are all slowly learning to appreciate the good qualities of the wonderful liquor which the old woman so mysteriously sold in the Chinese market place so long ago. It would not be surprising to find a school opened soon, to teach the girls of the artisan class how to make tea. It would be worth doing, for the liquor of the evergreen tree is marvellous in its quality, and the smell of the "tea-cans" of working men makes one shudder. We import good tea, but only the few know how to brew it. Good China tea comes to us, but only the rich use it. Indian tea is coming to us in ever increasing volume.

To look over the returns of the tea traders today gives one a start of surprise. Statistics are not as a rule good reading, but the meaning of the statistics of the tea men lies so close to the surface, that they are interesting to all. The figures here quoted are not for the entire year, only for the months between January 1 and September 30; but they show two things, first the enormous importation of tea; second, the direction of the trade.

CHINESE IMPORTATION, IN POUNDS.			
1888.	1889.	1890.	
148,426,476	.. 133,843,124	... 139,887,122	
INDIAN IMPORTATION, IN POUNDS.			
1888.	1889.	1890.	
66,955,507	.. 75,369,066	.. 89,133,628	

The steady increase in the latter figures is suggestive. One more statement, and I must close for today. The amount of tea imported into Liverpool in one year is about three million pounds, and careful men have calculated that this means an average consumption of 80 ounces per head, per annum. It will be found on examination, that most people consume a deal more than that; but the estimate certainly errs on the side of moderation, and may,

therefore, be accepted by all parties. The more tea people drink, the less intoxicants they will require; and the sooner we have classes to teach how to use tea to the best advantage, the better it will be for us all.—*Madras Times.*

DONATIONS TO THE PHARMACEUTICAL SOCIETY'S MUSEUM.

BY E. M. HOLMES, F.L.S., CURATOR.

JAVA.

Some months since, at the time that Professor Dunstan was investigating some of the wood believed to be the product of *Celtis reticulosa*, a specimen of which had been handed to him from the Hanbury collection, I wrote to the Director of the Java Botanic Garden to inquire, 1st, if several other trees which were known to the Malays by the same or a similar name had the same peculiar focal odour or were likely to contain the same principle, skatole; 2nd, if it would be possible to send for the Society's Herbarium specimens in fruit of the plants yielding the various false cubebæ that have entered into commerce; 3rd, if anything was known of the trees producing the Penang and Palembang benzoin of commerce, which differ in physical characters and odour, and are probably obtained from different species of *Styrax*; 4th, if the method of preparing the beautiful bright red dragon's blood in sticks from Pontianak was known. Some of the last named product was exhibited at the Paris Exhibition in 1878, and was considered by an artist to whom I showed it to be of sufficient value as a colour for inquiry to be made, if it could be regularly obtained in commerce. In reply to those inquiries I received, a few weeks ago, the following specimens and the accompanying letter from Dr. M. Treub, the Director of the Government Botanic Gardens in Java.

"Dear Sir,—I have the pleasure to inform you the despatch of a wooden case containing the following objects for your Museum:—

"1. Several pounds of ki-tai or kayoe tai from Java. [Prenger Regencies.] (A beautiful drawing of the *Celtis reticulosa* accompanied this specimen.)

"2. Dried herbarium specimens of *Cubeba mollissima*, *C. canina* and *C. officinalis*, with dried fruits and fruits from the latter in spirit.

"3. Benzoin (Palembang) as sold at Java.

"4. A piece of the wood of *Styrax Benzoin*, with the benzoin on the surface of the bark and a dried specimen of the plant.

"5. Dragon's blood from Borneo.

"(a) Djernang-koekoe, 3 pipes of dragon's blood with a fruit.

"(b) Djernang-mandai, 8 fruits in a little box.

"(c) Djernang berawang, 3 fruits.

"(d) Three cakes of dragon's blood wrapped in leaves.

"(e) Two flat cakes of the same not wrapped in leaves.

"(f) A small piece of dragon's blood said to be quite pure. [in a box].

"(g) Dragon's blood from Sumatra.

"The ki-tai or kayoe tai had been found to be the wood of *Celtis reticulosa*.

"Dr. Gustroff, who made a study on the subject, informs me that all the other plants said to yield skatole [*Premna corymbosa*, *Premna foetida*, *Saprasma arboreum*] do not contain it. They are only called ki-tai [stinkwood] by the Javanese because they all smell very bad.

"As to the origin of the false cubebæ sent to me, I am sorry to say that they are not known to me except the 'keboe-cubebæ,' which seems to be the fruit of *Cubeba mollissima*, Miq. [Miquel's commentatio de vero pipero cubeba, Leiden, 1838—1839]. I believe the others are not from here.

"From the benzoin enclosed in the case together with the dried specimen of the plant yielding it, you will see that there is no difference as to the botanical origin between the Palembang and Penang varieties. The en-

closed benzoin is sold at Java and is the true Palembang. Perhaps the Palembang benzoin in our Museum is old. If fresh it has the same colour as the Penang, and not that translucent appearance of the specimens you send me. It has quite the same colour and pale spots as your Penang. The piece of wood comes from Palembang.

"About the dragon's blood from Borneo I got the following information from the Resident of Pontianak.

"1. The cakes about three inches wide, a quarter of an inch thick and three inches long are not known at Pontianak. The Resident believes it is made at Singapore, and that from dragon's blood coming from Pontianak.

"2. The dragon's blood is brought in commerce in three forms:—

"(a) in flat cakes from very different dimensions.

"(b) in small cakes from about three or seven inches long and one inch wide.

"(c) in long pipes.

"The Resident had the kindness to send me the fruits of the trees from which it is obtained, and these being of different size, it is evident that there are at least three species of calamus which can be said to be the mother-plants of the dragon's blood.

"The smallest fruits give the most dragon's blood. This is said to be beautiful red of colour, but the tree is rare and the blood high in price.

"It only comes in very small quantities in commerce under the name of Djernang Mundai. The pipes inclosed in the case are from the fruits of greatest size. This is called Djernang Koekoe.

"The third variety in flat cakes from three by one inches is the Djernang Berowang.

"The fruits are of moderate size. For obtaining the powder the ripe fruits are shaken in a basket (as enclosed in the case). Mixed with water the powder is pressed in moulds and then melted.

"To give it more weight it is nearly always mixed with the milky juice of *Garcinia parvifolia*, Miq.

"The Resident believes that all the cakes and pipes are so prepared except the specimen *c*, which is said to be quite pure. I am indebted to Dr. W. Burck, Assistant-director and keeper of the Buitenzorg Herbarium and Museum, for the information contained in this letter.

"I remain, dear Sir, yours faithfully, TREUB.

"Director of the Government Botanic Gardens."

CURERS.

The specimens and information sent by Dr. Treub indicate that the keboek cubebs presented to the Museum some months ago is the fruit of the *Polygonum [cubeba] molleissima*, but that the large blackish cubebs with long stalks and the false cubebs generally referred to *Piper crassipes* are probably not exported from Java but from elsewhere.

BENZOIN.

The specimen of Palembang benzoin sent by Dr. Treub is scarcely a typical sample of the product as met with under that name in the London market. It has lost the opalescent translucency on the outer surface, but has the same lustrous fracture as Palembang benzoin, although darker in colour, as if it had been kept and exposed to the light for some time. It contains two or three white angular tears like those of Siamese benzoin, but the latter do not show any evidence of exposure to light.

The interesting point about Palembang benzoin is that whilst it has the same odour as ordinary "Sumatran" benzoin, it is more translucent and appears to contain a considerable amount of moisture, freshly broken specimens readily becoming mouldy when placed in a closed glass vessel. So far as I have been able to learn only one species of benzoin tree is commonly known at Palembang, and that, judging from specimens presented to the Society's Herbarium by Mr. R. Jamie in 1888 is undoubtedly *Styrax Benzoin*, Dry., as well as from the specimens from Java sent by Dr. Treub, since they have the globular fruits characteristic of that species. If the Palembang and Sumatran benzoin of commerce are derived from the same tree there is probably some difference in the mode of preparation; the Palembang variety may perhaps be

melted into blocks in hot water, and the Sumatra by artificial heat, and this might account for the moisture present in the former and the larger percentage of benzoic acid that it generally affords, but I have not been able to learn any facts tending to confirm this suggestion. The specimen of benzoin sent by Dr. Treub has the same odour as the Palembang and the ordinary Sumatran benzoin.

The odour of the Penang benzoin is so characteristic and so strongly resembles storax, that I cannot doubt it is produced by a different species. It is pointed out in the 'Pharmacographia' that *Styrax subdenticulatum*, Miq., occurs in W. Sumatra, and therefore in the province in which Penang is situated, and that this tree bears the same native name, "kajoe kemangan," as *S. Benzoin*, as if it yielded a benzoin. There is also a fragmentary specimen of another species from Penang in the Society's Herbarium, viz., *S. Portoricensis*, but I have no evidence to offer that either of them yield Penang benzoin. The subject needs further investigation, and I hope that Mr. H. M. Kidley of the Singapore Botanic Gardens, with whom I have also been in correspondence on the subject, may be able ultimately to clear up the matter.

Attached to the Java specimen are, some very curious galls of a cornucopia shape, developed at the expense of the flowers. These galls are produced in Java in such numbers that the production of fruit is much lessened thereby and consequently the spreading of the tree is considerably diminished. The insect producing the galls has been quite recently described as a new species of aphid by Dr. A. Tschirch (*Ber. der deutsch. Bot. Ges.*, 1890, p. 48), under the name of *Astegopteryx styracopila*, Tschirch. The interesting account he gives of these galls is accompanied by illustrations, both of the insect and of the structure of the galls (taf. iv.).

The specimen of the stem in section showing the gum resin oozing, does not bear evidence of the application of heat, although it has been stated that it is formed, under the stimulant action of applied heat, benzoic acid not existing naturally in the bark. Neither in this specimen nor in that of the Siam benzoin tree, presented by Mr. Jamie seven years ago, is there any evidence of treatment beyond the application of an axe or adze to gash the bark.

I may here take the opportunity of pointing out that the Siam benzoin, which has a distinct vanilla odour, is also the product of a different species of *styrax*. The leaves, examined in section by Mr. Shenstone, of Colchester, some years ago, showed sufficient difference from those of *S. Benzoin* to indicate that they probably belong to a different species whilst the drawing by Dr. Pierro in the Herbarium of this Society of the ovary of a species of *Styrax* from Luang Prabang in the Laos States, where the Siam benzoin is produced, shows an oval or elliptical outline, that of *S. Benzoin* being spherical.

DRAGON'S BLOOD.

Respecting the dragon's blood the information sent by Dr. Treub is both new and interesting. The dragon's blood of the best kind is evidently the produce of a species of calamus, different from that affording the inferior qualities. It may be hoped that the information thus obtained may lead to the cultivation of this rare species, and the production on a larger scale of so beautiful a product in a perfectly pure state. The species of calamus yielding the resin appear to be imperfectly known. The colour of the specimens in flat cakes, three inches long, one inch wide, and about a quarter of an inch thick, is brighter than in any of the other commercial forms of the article.—*Pharmaceutical Journal*.

POTASH FERTILIZERS.

The potash salts, which are used for agricultural purposes, are either directly or indirectly the products of the mines around Strassfurt, Germany. These salts are imported now in considerable quantities (last year's importation alone reaching an aggregate of 150,000 tons, an amount that will b

entirely inadequate when the true value of potash fertilization becomes better understood by the agricultural community). The potash salts, with the exception of kainit and sylvinit which are crude mining products, are concentrated articles.

The following presents a list of the various potash salts and their average composition:

Potash salts containing Chlorine.	Pure Pot-ash (K ₂ O)	Magne-sia (MgO)	Chlorine (Cl)
1. Kainit.....	12.8	13.1	31.1
2. Sylvinit.....	16 to 19	9.0	31.4
3. Muriate of Potash	53 to 58	0.3	46.0

Potash Salts free from Chlorine.

1. Sulphate of Potash	50 to 53	1.1	
2. Double Manure salt	27.2	15.8	

Whenever a soil is deficient in potash, it is necessary to resort to artificial fertilization to supply this deficiency. Sand and peat soils are always wanting in potash, while heavy clay soils, as a rule, are less deficient therein. And yet, by continuous exhaustive cropping, even these soils deteriorate and artificial application of potash becomes necessary, as the following table illustrates, which represents the amount of potash annually removed by a crop of various plants:

	Pounds of Potash.
Corn	113
Wheat	39
Barley	43
Rye	50
Oats	68
Peas	50
Clover	154
Potatoes	137
Tobacco	103
Grapes	88

These figures show to what extent even a rich soil gradually becomes deficient in this particular element, and how necessary it is to replace it, considering at the same time the requirements of the plant to be fed. Some plants with a strong appetite for potash have also the faculty of supplying their requirements in this direction from the soil, while others of a more dainty turn demand that their food be provided for them in an easily soluble form. To this latter class belong the cereals (wheat, rye, etc.) and also many fruit bearing plants, such as the vine, orange, peach, etc. Special attention should be given to the fact that, no matter how abundant the insoluble potash may be in the soil, soluble potash must be supplied in order to have the crop benefited by it. Consideration should likewise be given to the magnesia contained in some of the potash salts. Magnesia is a necessary element of plant food, and many soils are insufficiently supplied with it, as Professor Grandean has recently shown.

The Magnesia salts are also the active agents of potash fertilizers when used as manure preservers.

The success of potash fertilization depends, of course, largely upon the proper application of the various potash salts and the following principles should be kept in mind:

1. Phosphoric acid, nitrogen and lime, are, as well as potash, essential to plant growth.

A one-sided fertilization does not pay, except in very rare instances, and it is absolutely necessary to supply all these elements essential to plant life.

2. Leguminous plants do not require nitrogenous fertilizers.

Beans, peas, clover, vetches, and other plants belonging to the class of leguminosæ, possess the property of absorbing large quantities of nitrogen from the air, and therefore do not require nitrogenous manures.

3. Green manuring saves Nitrogen and brings profit.

The use of fertilizers frequently proves unprofitable through the great expense incurred in buying costly nitrogenous manures. This expense may be entirely avoided, if green manuring with leguminous plants is practiced. When peas, clover, etc., are liberally fertilized with potash and phosphoric acid, they grow luxuriantly, and when plowed under, the large amount

of nitrogen absorbed by them from the air suffices to insure a large succeeding crop. The abundance of organic matter, produced by green manuring, moreover adds humus to the soil and improves its chemical condition. Green manuring is consequently the best and cheapest method of restoring fertility to worn-out soils, and of making sandy soils productive. Green manuring by the use of leguminous plants (especially cow pea, vetch and crimson clover), in conjunction with potash-phosphate fertilization is sure to prove profitable and hence is of great value to the Eastern and Southern farmers in particular.

4. The use of lime should not be forgotten.

Soils, especially sandy soils, which are deficient in lime, even when overlaying a calcareous soil, require that it be supplied to them, if one wishes to obtain the benefit of other fertilizers.

5. Apply potash early and never use it as a top-dressing.

The potash salts are easily absorbed and held by the soil. If applied as top-dressing, they do not mingle with the soil, but remain near the surface beyond the reach of the roots. They should therefore be plowed under to the depth, to which the plant-root will reach, and this should be done a considerable time prior to the planting of the crop.

6. Thorough cultivation is essential to success with fertilizers.

A plant can only do its best, when the elements upon which it feeds, are presented to it under most favourable conditions. If by neglect of proper cultivation, a soil becomes hard, it offers resistance to the growth of the roots, and can neither absorb nor retain the moisture necessary to plant growth; under such conditions artificial fertilizers will prove of little benefit. To the objection, sometimes made, that artificial fertilizers stimulate the growth of weeds, it is only necessary to remark that the weed, as a robber, revels in a certain soil, and that what promotes the growth of the weed, renders the rightful owner of the soil also strong, and more profitable to the planter.

7. Potash salts must be applied intelligently.

An excess of chlorine in the soil injures the quality of certain crops, such as potatoes, tobacco, sugar-beets and oranges. Kainit, sylvinit, and muriate of potash, which are rich in chlorine, should therefore be avoided for such crops, and where a direct application is necessary, sulphate of potash and double manure salt should be used in preference. All objectionable effects, however, can be avoided, and all benefits retained, by applying potash fertilizers containing chlorine, a considerable time before the crops are planted, or better still, to the preceding crop. Either of these methods would prevent the injurious effect sometimes noted where the seed in planting comes in direct contact with crude fertilizers.

Observations especially important in the use of potash salts:

CEREALS.—Potash-phosphate fertilization for cereals is particularly remunerative when practiced in combination with green manuring through nitrogen-gathering leguminous plants. The nitrogen obtained by plowing under a heavy crop of cow peas, lupines or clover, suffices to produce a full crop of cereals if properly supplied with potash and phosphoric acid. An average quantity per acre is 200 to 450 pounds of kainit (or 50 to 125 pounds muriate of potash, and 400 to 600 pounds of 12 per cent acid phosphate). A larger amount of potash, is better for barley. If nitrogen is not supplied by manuring, a nitrogenous fertilizer must be used; 100 pounds of nitrate of soda per acre (or 2000 pounds cotton seed meal) is an average quantity.

MEADOWS.—The effect of potash on meadows is very marked, increasing not only the quantity of grass, but replacing the mosses and valueless herbs by nutritious grasses, (such as timothy, Italian rye grass) and other very desirable leguminous plants. The latter class of plants, to which various clovers and vetches belong, produces a very nutritious hay, and by their decaying roots, which contain a good deal of nitrogen, they furnish this valuable substance to the nitrogen consuming grasses. It is to be observed that the best results can be ob-

tained only when potash is used in conjunction with phosphoric acid; sour meadows likewise need a supply of lime. A normal amount of fertilizer per acre is 400 to 600 pounds of kainit (this salt is preferable for meadows) and 250 to 350 pounds of 12 per cent. acid phosphate. This application should be repeated every year, while the amount of phosphate given per acre may last for two years. The best time of applying is the fall. The best effect of fertilizers upon meadows rarely appears the first season, but one should not become discouraged for the benefit is a lasting, which will show more in the second than in the first season.

CLOVER, PEAS, LUPINES, AND OTHER LEGUMES.—Potash-phosphate fertilization will suffice to supply the needs of these plants which directly acquire their nitrogen from the air. They should receive 400 to 500 pounds of kainit per acre (or 100 to 130 of muriate) and 300 to 400 pounds of 12 per cent. acid phosphate. The lupine needs no phosphoric acid for fertilization; the power of the roots of this plant to assimilate phosphoric acid from the soil is so great, that a phosphate fertilization is apparently without effect, and potash alone will produce large crops.

POTATOES.—Care should be exercised in applying potash salts to the potato crop, otherwise damage will ensue by the chlorine, lessening the amount of starch contained in the mature tuber. This injury can be avoided either by using the more expensive sulphate of potash, or by applying the potash fertilizer to the preceding crop, or it can be lessened by spreading broadcast the previous autumn, by which the chlorine has time to wash into the subsoil during the winter. An average potato fertilizer is the following; 140 pounds of sulphate of potash (27 per cent. potash), 300 pounds acid phosphate (12 per cent.), 125 to 250 pounds nitrate of soda, or 250 to 500 pounds of cotton-seed meal.

TOBACCO.—What has been said about the potato applies equally to the tobacco, *i. e.*, that chlorine works injury to the quality in respect to combustibility and flavor. The difficulty is to be avoided in the same manner as in that of the potato, while no really good tobacco can be grown without the use of potash. The quantity per acre is 275 pounds sulphate of potash (low grade), 250 pounds acid phosphate (12 per cent.), 100 pounds sulphate of ammonia.

GARDEN CROPS AND VEGETABLES.—Potash is important in gardening, especially upon sandy soil. The requirements of different crops and soil are so varying that no universal formula can be given. For asparagus it is well to note that a heavy application of kainit (1,000 pounds per acre) together with a large amount of nitrate of soda has yielded large profits of a large and excellent crop.

FRUIT TREES.—Potash fertilization pays well in fruit culture as is well understood by every intelligent producer, and upon sandy soil a marketable article is impossible without it. The quantity may be varied as conditions vary; on an average 500 to 1,000 pounds of kainit (or 130 to 250 pounds of muriate of potash, or 240 to 470 pounds of low grade sulphate.) The quantity of acid phosphate (12 per cent.) may be varied from 300 to 600 pounds per acre. Nitrogen is chiefly supplied to orchards by manuring with leguminous plants (cow peas, vetch, crimson clover) combined with an occasional liming. Nitrogen fertilizers must be used where green manuring cannot be practiced—in strawberry culture, for example.

POTASH SALTS AS MANURE PRESERVES.

All kinds of animal manure when exposed to the elements lose a considerable part of their organic matter and nitrogen by decomposition. This loss, which usually amounts to about 25 per cent. of the nitrogen, can be entirely prevented by the use of kainit, which has the property of absorbing and retaining nitrogen and preventing a harmful fermentation, which likewise causes a loss of organic matter. In the use of kainit for this purpose, it is to be sprinkled daily in the stable, $\frac{1}{2}$ to 2 pounds for every full-grown animal being a fair average. By this proceeding not only a large amount of organic matter and valuable nitrogen is retained, but the manure produced is also enriched by potash.

POTASH SALTS AS INSECTICIDES AND FUNGICIDES.

The Experiment Stations of Texas, Louisiana and North Carolina and many observant farmers have directed attention to the use of kainit upon cotton fields, and its effect in materially checking the much dreaded disease of cotton blight. Some fruit growers think that the use of potash salts prevents rot and certain fungus diseases of the peach and orange. An interesting bulletin of the New Jersey Experiment Station (Bulletin No. 75) lately issued, gives the results of experiments, indicating that potash salts, and kainit in particular, destroys scales upon pear trees, grubs and cutworms in corn, plant lice, wire worms in potatoes, and cabbage mag-gots, and that no injury follows their judicious use.

WOOD ASHES, COTTON SEED HULL ASHES AND TOBACCO STEMS AS POTASH FERTILIZERS.

These materials are valuable for their contents of potash, and may be used as sources of this plant food in place of Strassfurt Salts. An objection to their use consists in the inequality of the composition, especially that of wood ashes. Their contents in potash varies from 3 to 8 per cent., while there is no difference in appearance to indicate the difference in quality. The contents of potash in cotton seed hull ashes range from 17 to 42 per cent., that of tobacco stems from 4 to 9 per cent. The great variability in composition of these fertilizers should therefore caution the farmer to buy only from the basis of a chemical analysis.

B. VON HESFF.

Washington, D. C.

—Florida Agriculturist.

Mr. D. Hooper, the Government Quinologist, has drawn attention to a report sent to the Board of Revenue on the *Vinca pusilla*. This plant is allied to the British Periwinkle and is called in Tamil *Mulakapoondoo*. It is said to be an excellent remedy for lumbago and is used largely on the western coast as an external remedy for such. The ryots of the South Arcot District say that if cattle graze upon it they become giddy and die. The sample forwarded by the Board for analysis to Mr. Hooper proved that the poisonous property of the herb was an alkaloid. *Vicine* is proposed by Mr. Hooper as the name of this new alkaloid.—*Madras Times*, Feb. 16th.

CHEWING TEA IN UPPER SIAM.—In the paper read by Mr. Ernest Satow, C.M.G., before the Society of Arts on 12th Jan., on "The Laos States of Upper Siam," the following occurs:—

Just at the bottom of the hill we passed a plantation of *mieng*, or Lao tea. The natives call these plantations *pa-mieng*, or tea-forest, if *pa* be rendered literally, this term causing it to be generally supposed that the *mieng* grows wild. Laos tell you that it is found growing in commixture with other trees, which are cut down, leaving the tea-tree to benefit by the additional air and sun. But this account seems doubtful. It is possible that the Laos of Chiengmai, when the country was resettled, found old tea-trees growing in this way, and cleared them from the jungle which enveloped them, but the arrangement of the trees is too regular to allow of our supposing that they were planted by the mere hand of nature. Many were twelve to fifteen feet high, with stems two-and-a-half to three inches in diameter, and they were evidently not pruned. Some were in bud or flower, and others bore the half-ripe berry. The leaf is longer and more pointed than that of the Japanese tea-plant, and the foliage is less dense. But of its being a species of tea there can be no doubt whatever. The Laos do not drink the infusion, but prepare the leaf for chewing by burying it in pits, and it is one of their indispensable luxuries. You see a man put a lump of the fermented leaves in one cheek, which he leaves there while he proceeds to chew betel or smoke a cigarette, looking for all the world as if his face were distorted by the mumps.

COFFEE IN BURMA.—At the annual meeting of the Agri-Horticultural Society on Saturday, writes the *Rangoon Times* of the 1st inst., Dr. Stephens compared a sample of coffee from Mr. Petley's estate in the Karren Hills with some coffee grown in the Society's gardens. The latter was so small that Dr. Stephens considered it was not advisable to propagate it, but advised the society to purchase Arabian coffee seed from Mr. Watson of Tavoy and to distribute plants at cost price and to encourage coffee growing as much as possible. Dr. Stephens considered that some of the Liborian coffee trees in the Society's garden which are 25 feet high should be sawn down, and a sucker allowed to grow up to 5 feet and then topped, as they will then give more crop, and it will be easy to gather. Ceylon was made by its planters, and the Straits Government is encouraging the planting enterprise as much as possible, but nothing is being done by our local Government to attract planters, or to induce the natives to cultivate coffee, &c.—*Pinang Gazette*, Feb. 10th.

THE TRAVANCORE GOVERNMENT AND JAFFNA TOBACCO.—We have in previous issues referred to the action of the Travancore Government in reducing the duty on Coimbatore tobacco, while maintaining the duty on Jaffna tobacco, the consequences of which has been the entire demoralization of the Jaffna tobacco trade, and the threatened ruin of thousands of cultivators. The Travancore Government, it seems, acted in anything but a straightforward manner, denying again and again that they had any intention of reducing the duty on Coimbatore tobacco, and then suddenly doing so. The influential memorial of 17th Dec. last from the leading residents in Jaffna to the Maharaja has brought no reply; and the memorialists therefore now intend addressing H. E. the Governor on the subject. It is almost a matter of life and death for Jaffna, Travancore being practically the only market outside of Ceylon for Jaffna tobacco; and we have no doubt that Sir Arthur Havelock will do all that he can to get justice done to the tobacco cultivators and traders of the north.

CINNAMON FOR INFLUENZA?—*The Produce Markets' Review* of Jan. 16th has the following:—

Cinnamon has long been known as a delicate spice of which the exquisite flavour and stimulating properties are insufficiently appreciated here, though they are far more valued on the continent. It has now, however, a fresh claim on the public attention, for M. Chambelland, of M. Pasteur's laboratory for the study of germs, has discovered that essence of cinnamon is the most powerful germicide as yet known, being even stronger for this purpose than corrosive sublimate. The following from the Paris correspondent of *The Daily News* gives the particulars as yet published:—"There would pretty certainly be a cinnamon boom if the experiment made with that spice by Mr. Chambelland in M. Pasteur's laboratory were generally known. Our ancestors, it appears, hit upon the best preservative from the infectious microbe when they used to drink mulled wines and other beverages in which strong doses of cinnamon were infused. Mr. Chambelland now says that no living disease-form can resist for more than a few hours the antiseptic power of essence of cinnamon. He looks upon it as not less effective in destroying microbes than corrosive sublimate. Even its scent kills them, and it does no harm to human beings. A decoction of cinnamon is often good to drink in localities where typhoid fever or cholera is rife." To combat the approach of influenza by adding ground cinnamon to puddings and tarts would certainly be a pleasant way of taking antiseptic precautions against the prevalent epidemic. Stick cinnamon burnt in the sick-room has long been known as an agreeable deodorant, but in the light of the above it may very probably be that it was originally its real antiseptic use

which suggested the idea. Essence of cinnamon in various forms is, of course, familiar to us all, when added to conceal the taste of physic; but the essence itself, as a medicinal germicide, would be an agreeable cure. On the continent, cinnamon is much more used in cookery than with us, and it is also supplied ready-mixed with sugar for sprinkling over cooked fruits pastry, &c.

BRITISH VEGETABLES.—Most of our vegetables are of foreign parentage. Many, like the sprout, onion, and bean, still bear the name of the places from which they were imported. Few can put it to their credit that they were born Englishmen and none can trace their descent through an unbroken line of British sap to the Norman conquest. Vegetables ranked much higher with the Greeks and Romans. Sparta's standing dish was the black broth, a vegetable soup, and a parsley crown was the prize of the winners in the Isthmian games. Many great Roman families took their names from the commonest vegetables; the Fabii from a bean, the Lentuli from a lentil, Scipio from an onion, and Cicero from a pea. Some people fancy that the Roman Church christened Lent from the lentil. The Egyptians made a god of the onion, and the comic Romans of the period sneered at the race which grew their divinities in their back gardens.—*Inverness Courier*.

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE,

COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for March:—

RICE.

he growth and preparation of rice for the market is dealt with in a bulletin issued by the Brisbane Department of Agriculture.

With regard to its value as a food, it is stated that the nutritious value of rice has hitherto been considerably underrated, that one pound of rice cooked for the table gave up 88 per cent of it back as nutriment, whereas the same quantity of beef only gave 25 per cent, and further that boiled rice was digestible in an hour, while roast beef (costing three times its price) took 3 hours. The following is the general composition of rice: water 13.7, flesh-forming substances 6.5, non-nitrogenous substances 79.4, ash .4 per cent.; while analysis shows rice to contain of starch 86.9, gluten 7.5, fatty matter .7, sugar and gum .5, epidrims 3.5, ash .9 per cent. The following comparison between rice and potatoes is interesting, as showing the former to contain three times as much nutriment:—

Rice.	Potatoes.
Water.....13.0	75.0
Flesh-formers....6.5	1.4
Starch, &c.....80.0	22.6
Total Food.....86.5	24.0

Thus 1 lb. of rice is equivalent to 4 lbs. of potatoes. Rice contains 70 per cent of starch. The great and rapid digestibility of starch, and the large percentage of carbo-hydrates or heat-producing substances it contains no doubt accounts for the fact of the coolies of our planting districts being able to perform so much work while subsisting on an almost pure rice diet.

To prove the prolific nature of rice, the result of an American experiment (which those who cannot conceive how paddy could give a

return of 500 fold, would do well to note) is given. A single grain is said to have produced more than ninety for the first crop, and over 110 for the second. After removing the imperfect grains, the whole number of grains from the one original grain was found to be 25,706!

Thrashing, to separate the grain from the straw and stalks; hulling, removing the outer skin or husk; separating, removing the trash and any unhulled grains; and finally, polishing, to complete the process of rice-cleaning for the market by removing the inner cuticle, may all be done by machinery, which can be purchased in sets or separately for either hand, animal or steam power. A complete set of hand-power rice-cleaning machinery, with a capacity of from 300 lbs. to 500 lbs. per day, will cost £53 2s. 6d. in New York; a set for animal power of the same capacity, £87 1s. The best known manufacturers of rice-cleaning machinery are George L. Squier Manufacturing Company of Buffalo, New York.

Such machinery is a great improvement on the primitive methods adopted for cleaning rice in Eastern countries. The mode of thrashing paddy by trampling with bullocks, and winnowing the grain by dropping it from a height in a light breeze are too well known to need description. The hulling or husking of paddy is, however, done in more than one way:—1. The implement most commonly used by the natives of India consists of a heavy beam of timber about 8 feet long, into one end of which a short shaft shod with iron is fitted at right angles to the log. The centre of the beam rests on a cross bar, to which it is fixed, resting upon two uprights sunk into the ground. The iron-shod shaft rests in a wooden cup sunk below the level of the ground. The implement is worked by one or more persons pressing the free end of the log down with one foot, and letting go, when the shod ends drops into the cup holding the paddy. 2. A second im

plement is in reality a pestle and mortar made of wood. This is commonly used by the natives, and a modification of the first-mentioned implement as well as the second are used also for smashing rice and for pounding it into flour. 3. Another system of husking is to pass the paddy through a small pair of millstones or cylinders of the same shape, made of hard wood, set on end and grooved on the working surface. The distance between is regulated, so as to remove the husk by friction without breaking the grain, the grain and the chaff being afterwards winnowed. After husking in this manner the inner skin covering the grain has to be removed by pounding in a mortar. This implement is a modification of the stone mills used for grinding paddy and gram for feeding horses. The greater portion of the paddy prepared for the market in India is said to pass through a steaming and soaking process before being husked, to facilitate the removal of the husk and minimise breakage. The paddy is steeped in water for 48 hours, and is then put into another vessel with a small quantity of water and placed over the fire; just sufficient water is used to merely steam the contents. After this it is dried thoroughly in the sun for two or more days and then pounded in the mortar before mentioned. It will thus be seen that all these processes are slow and tedious; but with the use of a modern hulling machine, the thrashed paddy has only to be put into the machine, and it is delivered clean rice. Our poor paddy cultivators cannot of course be expected to purchase patent machines, but their wealthier brethren might well import a few and set them up in central places, so that the goiyas round about may benefit by them. A huller alone can be procured from America for £16 13s. 6d.

OCCASIONAL NOTES.

On another page will be found the beginning of a list of names of the varieties of paddy grown by the natives of Ceylon. Some of these are no doubt different names for the same variety, as has been found to be the case with the large number of specimens of paddy stored at the School of Agriculture. Of these a collection of 240 distinct varieties have been made up for the Imperial Institute. The list which is being given in this Magazine furnishes the largest number of names we have been able to collect; and for that reason it will be of some interest.

A parcel of seed has reached us from Brisbane, having been sent for experimental cultivation. The seeds which are those of a salt-bush (most likely *Artiplex Spongiosum*) are as small as mustard-seed, but flattish, and are contained in a spongy covering. The salt-bushes are used as fodder, and are specially suited to dry saline soils—the only specimen indigenous to Ceylon being *A. repens* mentioned by Thwaites as occurring in the north of the island. *A. spongiosum* is described as being particularly good for sheep pasture. *A. Nannularium* is one of the tallest, most fattening and wholesome of the salt bushes for sheep and cattle. Sheep feeding on it are said never to be affected by

liver fluke, and to get cured if suffering from the distoma worm and other allied parasites. *A. Halimoides*, a common dwarf shrub in Australian deserts, is also a good forage plant, while *A. Vesicarium* is described as the most fattening and most relished of all these salt bushes, holding out in the utmost extremes of drought. The seeds which have reached us from Brisbane have been sown and have germinated well, but the seedlings look very weakly, it may be owing to the excess of moisture they have been supplied with since they have been put into the ground.

A very "catchy" advertisement has been appearing in the *Ceylon Times*, referring to *Lathyrus Sylvestris*, which is being grown experimentally in the School of Agriculture grounds. Since our note about this fodder plant in our last issue, our hope in the success of *L. Sylvestris* has not increased. The plants that have come up in good soil are looking by no means flourishing, and do not seem as though they were going to survive the two years after which they would be fit for cropping. Only two plants, specially cared for in a flower pot, with the object of securing a blossom, can be described as vigorous growths. Those planted in a sandy soil have all died out. Considering that the extravagant theory of Mr. Reeves, as to plants deriving all the elements of their food (both combustible and incombustible) from the atmosphere, was founded on the fact that *Lathyrus Sylvestris* flourished apparently independently of what the soil contained in the way of plant food, it seems strange, to say the least of it, that this "air plant" should need so many luxuries in Ceylon.

The *Kew Bulletin* for October and November last contains a paper on Chinese fibres. *Abutilon Avicenne*, an annual, belonging to the order Malvaceae, produces a fibre which is sometimes found to be as much as 15 feet in length. In Ceylon we have six species of *Abutilon*, viz., *A. Polyanthum*, *A. Asiaticum*, *A. Indicum*, *A. Graveolens*, *A. Crispum*, and *A. Muticum* (*A. Tomentosum*). These are all spoken of generally by the Sinhalese as *Anoda*, a name which, however, properly belongs to *A. Asiaticum*. *A. Leschenaultianum* also occurs as a weed, but is it doubtful whether it is indigenous to the island. *A. Indicum* which yields a strong fibre that can be worked into ropes, is known as the country mallow, and is used medicinally in the same way as the English mallow. *A. Polyanthum* also yields a long silky fibre resembling hemp. The product of *A. Avicenne* is known as Chinese uto.

Corchorus capsularis is another fibre-producing plant of China, belonging to the order Tiliaceae. It is found in Ceylon together with *C. Olorinus*, *C. Urticifolius*, *C. Fascicularis*, *C. Tridens*, and *C. Acutangulus*. *C. Capsularis* is the plant which produces Indian jute. Besides the gunny bags made from the bark, the stems of the plants themselves are used for charcoal for gunpowder, fences, basket-work, and fuel. Drury mentions that the fragments of the stem which are cut off nearest the root are shipped to America from Calcutta for paper-making, preparing bags and such like purposes, and even for making whisky.

C. Oltorius called Jews' mallow (owing to the Jews, like the Indians, eating the tender leaves and stem as a vegetable) also yields a fibre used for making sack cloth, cordage and even paper. The fibre is said to be long and fine, and such as might well be substituted for flax.

Pandanus Odoratissimus produces a fibre of poor quality, which is used in Fiji for making mats. This plant occurs in Ceylon, and is very abundant near the sea. It is known among the Sinhalese as Madu-keyiya, and commonly spoken of as the screw-pine. There are three indigenous varieties of *Pandanus* in Ceylon—*P. Odoratissimus* (*P. Fascicularis*) already mentioned, *P. Humilis* (*P. Foetidus*) the Sinhalese Dunn-keyiya, and *P. Furcatus*, the Sinhalese Okeyiya, all of which are more or less used for mat-making by the natives. The two latter are common hedge plants for paddy-fields in the warmer parts of the Island.

Boehmeria Nivea is the rhea fibre or China grass out of which most of the so-called grass cloth is made. In Ceylon we have *B. Malabarica* (Sin. Mahadiya dool) which is very common throughout the island. The bark of this plant is used by the Sinhalese for fishing lines. *B. Platyphylla*, with its varieties *Macrostachya*, *Zeylanica*, and *Rugosissima* are common in the Central Province up to an elevation of 6,000 ft. *Sterculia platanifolia* produces a fibre from the bark of young trees which is used for making cordage. In Ceylon we have *S. Balanphas* common in the hotter parts of the island producing the Nava hemp, *S. Fetida*, the Sinhalese Telamboo also very common in the warmer parts of the island, *S. Urens*, the Tamil Kavali, *S. Guttata* found in the Ambagamuwa district, *S. Coloraba*, and *S. Thwaitessi*. *S. Acuminata* affords the Kola of the Africans.

TWO CEYLON GRASSES.

Cynodon Dactylon, a common grass in Ceylon, especially in the warmer parts of the Island, is known among the Tamils as Arugampilla, in Southern India as Huryalee, and in North India as Doob. It is considered to be a splendid fodder, and is generally sought for by sellers of natural grasses. Isa Tveed, the author of a work on Dairying lately published in Calcutta, says it is by far the best grass for cattle in India. *C. Dactylon* is also found in England and other parts of Europe, as well as in China, Thibet, Australia, South and Central America, and Cape Colony. Sir William Jones mentions that it is said to be the *Agrostis* of the Greeks, and that its usefulness, (being the sweetest and most nutritious pasture for cattle) added to its beauty when in flower, induced the Hindoos to look upon it as a sacred plant. In the New South Wales *Agricultural Gazette* for May last, it is figured and described as Couch grass or Bermuda grass. It is there mentioned as a most valuable pasture grass which stock of all kind eat greedily and fatten on. Its underground stems are said to possess some of the medicinal properties of Sarsaparilla, the juice being also used as an astringent and diuretic. The

following is the chemical analysis of the young grass: Albumen 1.60, Gluten 6.45, Starch 4.00, Gum 3.10, Sugar 3.60 per cent.

Some months ago we applied to the Government Agent of the Northern Province for some seed of what is known as Delft grass, that is the grass common to the Island of Delft, and which we have heard spoken of as an excellent fodder. In answer to our request we received a few plants of the grass, with the promise that we shall have the seed when it was available. The plants sent us as Delft grass have come up well and are now in flower, and Dr. Trimen, to whom we referred specimens for identification, thinks the grass is *Andropogon Versicolor* (a variety of *A. Schoenanthus*), a kind of small mana grass, with a peculiar scent in the leaves. Thwaites mentions that the grass is found in the more elevated parts of the Central Province, that the inflorescence when crushed has a rather aromatic odour, and that the essential oil appears to be situated principally at the base of the spikelets. Mr. William Ferguson mentions the grass as one very common at Wilson's Bungalow, and says that specimens grown in Colombo had a light green colour, and when bruised in a fresh state had a strong smell of anise. These qualities are just what characterize our own specimens at the School of Agriculture. The grass, says Ferguson, may be called the Anise-scented grass. It is curious that none of the authorities quoted above make mention of Delft in connection with *Andropogon Versicolor*. The grass seems rather coarse, and altogether strikes one as not being a grass that cattle would care to eat much of. In order to make sure that *Andropogon Versicolor* is the true Delft grass, specimens of those growing at the School of Agriculture are being sent to Jaffna for comparison with the grass as found growing in the Island of Delft.

INDIGENOUS FOOD PRODUCTS: CULTIVATED AND WILD.

By W. A. DE SILVA.

Labiatae.

64. *Leucas Zeylanica*, Br. Sin. Getatumba, is a low shrubby plant growing in uncultivated places and waste lands. The leaves are small, lanceolate, and of a bright green colour with a hairy surface. Small flowers, with a cup-shaped calyx, and a white corolla, are borne in a raceme with compressed peduncles. The leaves when bruised have a peculiar smell. These leaves are often eaten along with rice, either boiled or made into curries. They possess rather a bitter taste which some however like. The plant is much valued as a medicinal one, for the boiled leaves are an excellent remedy in bowel disorders. It is also used in mild fever caused by indigestion, and to relieve pain due to intestinal worms. Externally the bruised leaves are applied in dog bite.

Nyctagineae.

65. *Boerhaavia Diffusa*, L. Sin. Pitasudupala. This is a herb growing in waste lands, and especially in fertile spots, such as the sides of

drains or on rubbish heaps. The plant is much branched and the stems and branches are of a succulent nature. The plant is covered with succulent ovate leaves, and the under surface of the leaves is of a whitish colour, whilst the upper is green. Owing to this peculiarity, the Sinhalese call it Pitasudu, or white-back. The plant bears small flowers with pinkish corollas. The leaves and the tender stalks are used as a food made into curries. This plant is much relished by cattle, and might with advantage be cultivated as a fodder. Native medical practitioners ascribe to this plant the property of helping digestion.

Amarantaceae.

66. *Amaranthus Speciosus*. L. Katutampala.

This is a plant found growing as a weed in cultivated places, especially in vegetable gardens. It is also frequently met with in waste lands on fertile soils. It is a green, succulent herb, generally much branched, and growing to about two feet in height. The leaves are small and are of a green colour, and the stem, at the nodes, contains small prickles, which are very abundant in the tender parts. On account of these prickles, the plant is often known as the Prickly *Amaranthus*. The leaves and the tender stalks are used as a vegetable for curries. This plant has attracted some attention in India and elsewhere as a probable source of good fodder. Mr. J. Howard De Rinzy, in his evidence before the Vegetable Products Commission of Victoria says, that the Prickly *Amaranthus* grows freely in cultivated land, on waste or stony patches; that it is highly lactiferous, and is given to milch cows largely, mostly boiled with pulses; and that the tender tops are said to be a good vegetable. He has recommended the plant as suitable for cultivation for small farmers, especially as a fodder crop for milch cows.

THE CULTIVATION OF THE COCONUT PALM.

It is of course perfectly clear that *ceteris paribus*, the richer the land the finer the trees and the more generous their yield. In the Eastern Province, and especially in the Batticaloa district, the most successful estates are those which were established on wild-mango forest land with a rich compost of decayed leaves and twigs some feet deep. The wild mango is a tree with a soft bark which is annually renewed, the old bark dropping down to the ground and generally supporting a growth of vari-coloured saprophytic fungi. Nearly every estate has its bad patches of land, where the water lies stagnant, or the soil is sour, with useless and objectionable grasses and other weeds which are troublesome to get rid of. The marshy parts of an estate must of course be drained by means of channels cut to carry the water into a tank or pond in the lowest ground, or if practicable, into a river or stream. Marshy plots will at first show slow growth, but in after years when the palms are well established they seem to flourish amidst their humid surroundings and bear profusely. On Chandivelly, Curativo, and Linsagoor estates in Batticaloa and in many other places I have noticed this, and the same results are

seen in the case of the palms which grow on the seashore. I am inclined to think that salt in moderation acts beneficially on the coconut tree, and large trees watered with salt-water showed apparently good results. Aerially estate, in Jaffna, once the property of the late Mr. Price, was liberally and solely manured with seaweed, and bore crops that delighted the proprietor's heart.

It is unwise to clear a young estate of grass or weeds and shrubs in the hot season. Such growths afford shade, moisture and perhaps nutriment to the young plants, but in the rainy season weeding may be done with impunity. The natives follow this plan, which they have found by experience a good one. On newly-opened properties, they even go the length of cleaning the ground along the rows of plants, encouraging the growth of shrubs along the middle line.

It may be taken as an agricultural axiom that one small shower of rain does more good than one month's tedious watering, but when the plant or tree is in need of water, it should never be allowed to go without it at any cost. It is most necessary to fence new plantations till the trees are above the reach of depredators. This can be done with the forest timber, but it is advisable to put in at the same time seeds or slips which will grow into live fences which give little trouble except that of binding the trees horizontally. There are many trees suitable to form live fences, but in the Eastern Province aloes and fence-crotons are put down. Here as well as in Jaffna, palmyra seeds in two or three rows are put down at the same time as the coconuts, and will in time grow into a magnificent and impenetrable fence, as the spines on the leaf stalks are sufficient to keep away intruders as effectually as patent barbed wire fencing. Another advantage which however is very slow in reaching the proprietor is that the palmyra will yield a magnificent supply of timber for buildings or selling. The fruits (which cattle are very fond of) and other products of the palmyra, moreover, are not to be looked down on; not the least valuable of these being the jaggery or coarse sugar prepared from the toddy.

R. ATHERTON.

VARIETIES OF PADDY.

The number of varieties of the paddy plant (*Oryza Sativa*) is so great in that it has baffled the most careful student to make anything like a correct list of them. Besides these, numerous varieties are known in different countries, and even in different districts of the same country, by widely different names; hence it is almost impossible to make anything like a complete list without at first procuring samples from all rice-growing countries. The largest number of varieties of paddy brought together at the Colombo Agri-Horticultural Exhibition was two hundred, for which a Gold Medal was awarded to the exhibitor, and the collection made in Ceylon for the Imperial Institute numbers about 240.

A prize was offered in the December number of the Sinhalese Agricultural Information Leaflet for the best list of paddies grown in Ceylon with the approximate periods of growth. In response to this more than thirty lists have been received, the best of which gives about 460 varieties. There are no doubt many repetitions in this list, but it is still valuable as a collection of the largest number of names of the varieties of Ceylon paddy—

The list is as follows:—

	Months.		Mot hs.
1	Pihatuwi	5-6	3-3½

FRAGRANT PLANTS.

Many plants belonging to the order *Labiata* are characterised by a pungency and odour (not always pleasant) about their leaves. Among fragrant or aromatic English plants of this order may be mentioned Lavender, Mint, Peppermint, Pennyroyal, Basil, Thyme, Marjoram, Savory, Sage, Palm, Rosemary, Wild Thyme and Sage. Of the family *Ocinum* (belonging to this order) we have in Ceylon, *O. Canum* (Heen-talla) and *O. Basilicum* (Sweet-Basil) are common about native gardens, *O. Gratiissima* (common in the warmer parts of the island); *O. Suave* (not common), and *O. Sanctum* (Holy Basil), known as Madooorootalla among the Sinhalese, who use it much as a medicine and for keeping away insects (madooroo). And these are more or less fragrant and aromatic, and some (as the first two mentioned) are used for seasoning dishes. The family *Plecthranthus* includes *P. tuberosus* (innala) the tuberous roots of which form a delicious aromatic vegetable.

Coleus aromaticus is the Sinhalese kappawalliya. Roxburgh says that every part of the plant is delightfully fragrant, and that the leaves are frequently eaten with bread and butter. *C. Barbatius* also possesses a strong but not disagreeable smell; its roots are pickled and eaten by the natives of Bombay.

Patchouli (*Pogostemon Patchouli*), of which Drury says:—"The odour is most powerful, more so perhaps than that derived from any other plant," is not infrequently met with in Ceylon, though not indigenous to the island, but *P. Heyneanus*, which is indigenous and common enough, is probably merely a variety of *P. Patchouli*, and is known among the Sinhalese as gang-kolung-kola. Other varieties of *Pogostemon* found in Ceylon are *P. rupestris* and *P. reflexus*. The leaves of Patchouli, powdered and put into bags, are said to prevent clothes from being attacked by moths; by the Arabs the leaves are used for stuffing mattresses and pillows, as it is thought to be efficacious in preventing contagion and prolonging life; it is also used in India for mixing with tobacco. The essential oil

was at one time very valuable, but the scent seems to have gone out of fashion somewhat. A small quantity of leaf is even now exported from Ceylon.

GENERAL ITEMS.

Mr. P. B. Kehelpannala writes:—The Eramadu or Erabado, also known as the Indian Coral tree (*Erythina Indica*) is useful in many ways to the natives of Ceylon. In the north of the island the leaves are used as food for cattle, but in the Sinhalese provinces they are only given to calves and rabbits. The leaves are also pounded with coconut, turmeric, &c., and the juice expressed from the mixture is used medicinally to prevent parasitic attack, and for this purpose is applied to the naval of newborn calves. The leaves are even eaten by the poorer classes, in the form of a dry curry. Stumps of the tree are used for live fences, while the wood of the trunk, though by no means durable, is used in constructing dwellings. The tree is grown as shade for cocoa, and as betel and peppervine supports. The tree begins to blossom about the time of the New Year, and this fact is referred to in Sinhalese poetry, for instance: *Auruddut Kittai, Eramadu mal-ut Kuppei*." The year is close at hand, the flowers of the Eramadu are budding. By subjecting the seeds to pressure an extract is got which is used as an ointment that is applied to sprains, and is also recommended in cases of wasp-bite. It is said that the wasp when he drinks the sweet nectar of the bright and attractive scarlet flowers, gradually loses its vital powers and ultimately dies.

In *Nature* for November 5th, 1891, Mr. W. B. Hemsley, reviewing two German works on coast vegetation, says, on the authority of Mr. C. B. Clarke, that in such localities the "milk" (coconut water?) of the coconut is so salt as to be undrinkable.

Australasia imports annually nearly 20,000 tons of rice, worth £250,000.

Professor Wallace, in his address on Egyptian Agriculture, states that the chief crops are cotton ("by far the best paying crop"), maize, birsem (*Trifolium Alexandrinum*), a kind of large-growthed clover with a white flower, beans, wheat, and barley; Sesame (sesamum or gingelly?), sorghum vulgare (Tann. cholom), sugar-cane, and rice are also grown; and potatoes have been lately introduced and found to be a great success.

Cattle are very fond of the tender parts of the dball plant (*Cajanus Indicus*) both in a green and dry state. The dry stems are said to be excellent fuel and well-adapted for producing fire by friction. The leaves rubbed with pepper cleanse the gums and are also given in toothache. A drink is also made from them and administered to small-pox patients.

The stud bull at the School has had a bad time of it with an attack of foot-and-mouth disease, but with care the valuable animal has recovered, and the disease was kept away from Mr. Jayawardene's milking stock.

The Agricultural Improvement Society met on the 1st Friday of February, when Mr. Attepattu read an instructive paper on coconut cultivation.

A Training School and Practising School (for training Government School Teachers) have been established at the School of Agriculture. Mr. C. Silva, Muhandiram, late headmaster of the Bentota Training School, has been appointed headmaster of the latter, and Mr. D. A. Silva has taken up duties as headmaster of the Practising School, with Mr. Gabriel as his assistant.

Mr. W. A. De Silva, 2nd assistant teacher at the School of Agriculture, leaves for Bombay in May next, to go through a thorough course of Veterinary training at the Veterinary College there. Mr. De Silva will hold a Government Scholarship while prosecuting his studies in India.

Mr. Seneviratne, a passed student of the School,

has been appointed Science teacher at the Buddhist College just started in Galle.

A fairly large piece of the new land granted to the School has been put under dhall. It would be an excellent thing if the poorer section of natives in Ceylon took to the cultivation of dhall in their little patches of land. Our agricultural instructors have been instrumental in introducing the plant as a valuable food product to the people of many districts. On the poor soil about the School we are growing it, (1) because it grows well even in a poor soil, (2) because it will improve the soil—as we have known it to have done before—being a leguminous plant, (3) because it forms a palatable and nutritious article of diet, and (4) because we shall be able to supply our agricultural instructors with fresh seed.

Ground nut, areca-nut, Singapore pepper and cocoa have also been put down in the School grounds. The first-mentioned, which it is intended to grow more of, is now in fruit.

THE TROPICAL AGRICULTURIST

MONTHLY.

Vol. XI.

COLOMBO, APRIL 1ST, 1892.

[No. 10.]

TEAK.

PAPER has recently been read by Mr. Ernest Satow C. M. G., before the Society of Arte, which affords to us much interesting information with respect to the prospects of the teak exports from

the forests of the Malayan peninsula. We here in Ceylon make but little use of this timber, save perhaps in our railway department, but solely because its price is almost prohibitory. Were it not for this latter fact, the almost unapproachable qualities of Moulmein teak must have ensured for it a very much larger use than it now has in this island. Our supply of this timber is, we believe, largely made up of drifted logs which come ashore on our eastern coasts that are claimed and disposed of by our Colonial Forest Department? It is, we think, the case that the demand for teak timber for the construction of our railway carriages is one of considerable amount, and doubtless the Railway Department will be concerned to hear that Mr. Satow has declared, as the result of his visits to the forests of Burma and Siam, that unless some change can be made in the system of working, or some very material increase of price can be obtained, in about ten years' time it will no longer pay to cut teak in the forests of those countries. We had no idea, until we had read what Mr. Satow has said on the subject, that the preparation of teak for export was such a long and expensive matter. In the first place, he has told us that operations commence by cutting a ring in the bark of the tree about four feet above the level of the ground. This kills the tree, and it is left standing *in situ* for three years, so that the wood may become thoroughly dry before felling. At the end of that term financial difficulties begin to operate. The forests are leased from the chiefs, mainly by British Indian subjects, who let their concessions out under numerous sub-leases. Of these sub-lessees the foresters purchase the right to fell, paying, we are somewhat surprised to find, as high a royalty as three to four rupees for the right to fell each tree. These third parties to the transaction, who are the practical

men, are rarely possessed of capital, and they have to borrow from money-lenders at a high rate of interest. And, as it appears, is a frequent requirement of these practical men, because it is so largely dependent upon the rainfall as to whether the rivers possess a sufficient flow at the proper season to float the logs down to the sea coast. If this be deficient, the foresters may have to wait a whole year, or even more, before they can obtain any return upon their outlay. Then there is often a deficiency of the elephant labour required to drag the heavy logs from the forests to the river bank, and when obtained the delicacy of these huge animals is so great that after working for three days only they have to be rested for five days. But these are by no means the only elements of uncertainty and expense attendant on the trade. The Siamese Government extorts a duty of four rupees per log, and many of these logs are lost by being carried out to sea during froshets, a considerable proportion of them finding, as we have said, their ultimate destination on the eastern shores of this island. When, in conjunction with all these hindrances to profit, Mr. Satow tells us that it sometimes takes three years from the date of felling before any return can be obtained, we can feel little surprise at the price here being so nearly prohibitory as we have mentioned it to be. At Moulmein there is a large demand for the outside slabs for cutting into shingles, while at Bangkok no such demand exists. As the result, logs which sell for from 80 to 100 rupees at the first mentioned place fetch only about 35 rupees at the second. It will be seen how many elements combine to make the profits of the teak cutter both uncertain and fluctuating; and these elements, if they cannot be overcome in some way or other, threaten ere long to cut off the supply of this valued timber, one which it would be very difficult to find a substitute for.

GRAPHITE.

The following article from the *American Engineering and Mining Journal*, by Prof. J. F. Kemp, School of Mines, Columbia College, New York, is interesting as showing that graphite mining from rock containing only 10 per cent of the ore is carried on in the United States merely as a check on the price of the Ceylon article, of which nearly 256,000 cwt. valued at \$594,746 were imported into the States in 1890, by far the highest figures on record. The value of all the plumbago produced in the United States is only about \$35,000, and Canada shows only \$3,000

dollars. So that the fine ore from Ceylon has the markets of Britain and America practically to itself.

Graphite is a mineral of metallic luster, its color ranging from iron-black to dark steel-gray. Its hardness is 1-2 and its specific gravity from 2.25 to 2.27. It soils paper and has a greasy feel by which it is easily recognized, being distinguished from molybdenite by the streak, that of molybdenite having a slightly greenish cast. Molybdenite also affords a test for sulphur before the blowpipe.

OCCURRENCE.—Graphite is a very common and abundant mineral in many regions of metamorphic rocks, and has attracted attention in various parts of the country. The only locality which has proved as yet an important producer, however, is Ticonderoga, N. Y., and its neighborhood. The old mines by which the place is best known are on a series of elliptical oblongs in gneiss which are filled with calcite and graphite. They were long since exhausted. The present source is a graphitic quartzite or schist in the town of Ilagoo, N. Y., some five miles west of Lake George. There are crystalline limestones along Lake Champlain which also contain graphite, and might furnish the mineral. Any rock employed for this purpose must be free from mica, for it is impossible to separate two so closely minerals in the dressing.

A crude graphite, adapted for the manufacture of crucibles, stove blacking, etc., is found in conjunction with anthracite coal in Rhode Island. Graphite is also mined in Pennsylvania, Michigan, and Wyoming. Other deposits are known in this country, but none of them are worked. Most of the graphite used comes from Ceylon.

PREPARATION.—The rock consisting of about 10 per cent graphite and the remainder quartz, which is worked at Lake George, is crushed in a battery of California stamps and then washed with buddles and settlers, the percentage of graphite being thus raised to 40 or 50 per cent. This product is further treated at Ticonderoga by a secret washing process, whereby the grade is raised to 99 per cent.

PRODUCTION.—The quantity of graphites produced at Ticonderoga is not large, and could doubtless be considerably increased. The mines are owned by the Joseph Dixon Crucible Company and serve as a check on the price of Ceylon graphite which is principally used by that company. The production of graphite in the United States, together with the imports into the country, is shown in the following table:—

Year.	Production.		Imports (d).		Total Value.
	Amount lb.	Value.	Unmanufactured.	Manufactured.	
1880.....	(a)	\$300,963
1881.....	(a)	413,640
1882.....	(a)	31,974
1883.....	(a)	381,968
1884.....	(a)	363,835
1885.....	(a)	359,371
1886.....	(a)	28,536
1887.....	(a)	34,000
1888.....	(a)	154,552
1889.....	(a)	31,549
1890.....	(a)	383,670
1891.....	(b)	288,256
1892.....	(b)	1,863
1893.....	(b)	207,228
1894.....	(b)	184,111
1895.....	(b)	331,621
1896.....	(b)	353,990
1897.....	(b)	378,057
1898.....	(b)	594,746
1899.....	(b)	594,746
1900.....	(b)	594,746

(a) In 1880 the production of crude graphite amounted to 940 short tons, valued at \$40,800; in 1889, 7,003 tons, valued at \$72,662. (b) The production in 1884 was practically nothing. (c) From 1880 to 1888 the imports are for fiscal years ending June 30; subsequently, calendar years.

A considerable amount of graphite is used in its crude state for foundry facings, etc. Thus it will be observed from the preceding table that the production of refined graphite in 1889 was but 400,000 lb. valued at \$33,000, while the output of crude graphite was 7,003 tons, valued at \$72,662.

Uses.—Graphite is largely used for pencils, and as a lubricant, for both of which purposes it must be soft and of high grade. Lower grades are used for crucibles, stove blacking, foundry facings, and as a substitute for red lead in pipe fitting. It is also being extensively employed as a paint for covering smoke stacks, boilers, tin roofs, etc., having been proved to be very durable. Recent experiments have shown that a graphitic lining for Bessemer couverters is especially adapted to withstand the outgassing action of acid slag, and a large demand for graphite has come from steel works in consequence, especially in Germany where this material has been adopted by the Krupp works. Thus, the imports of graphite into Germany, from Ceylon, are said to have increased from about 3,100 cwt. in the year ending June 1st, 1889, to 14,215 cwt. in 1890, and 11,000 cwt. in 1891. The decrease in the last year was occasioned by the falling off of the output of Ceylon, from which island 148,000 cwt. of graphite were exported during the year ending June 1st, 1891, against 162,000 cwt. in the twelve months preceding.

Price.—The price of graphite or plumbago, as it is commonly called, varies according to its quality. It is divided into four grades, viz.: Large lump, ordinary lumps, chip, and dust. Large and ordinary lump are now worth from \$4.00 to \$5.00 per cwt.; chip, from \$3.50 to \$4.00 and dust from \$2.75 to \$3.50. The quality of plumbago depends as much upon its physical structure as upon its chemical composition.

To the above we add the following:—

FORMATION OF GRAPHITE.—In a paper on the formation of graphite by contact metamorphism, by R Beck and W. Lnzi—*Journal of the Chemical Society*—the authors claim to have discovered some beautifully crystallized graphite in rocks which have been metamorphosed by contact with ancient volcanic rocks, the graphite crystals are easily discernible from the amorphous carbonaceous substances of the original clay slates and siliceous slates. The authors have proved that graphite has been formed from carbonaceous substances by contact metamorphism in the case of certain rocks in Saxony. In Pirna and Kreischa, upper Silurian clay slates and siliceous slates occur, which are very rich in carbonaceous substances, and lie partially within the region of contact of the granite and hornblende granite; those within this region of contact have become converted into graphitic rocks. A chiasolite slate and a graphitic quartzite were examined. The graphite had a greasy feeling, and produced a metallic streak; it had also a metallic luster. Analysis showed that the graphite from the chiasolite slates had the composition C=93.84 per cent, H=0.21 per cent; while that from the graphitic quartzite had the composition C=99.94 per cent, H=0.05 per cent. The graphitic quartzite itself contained over 2 per cent of graphite, and its specific gravity was 2.62—2.637. Proof is therefore afforded by this discovery that graphite is formed in nature from amorphous carbon in much the same manner as it is produced artificially.—*Engineering and Mining Journal.*

TEA AS A BEVERAGE.

Tea, as a beverage, is being "boomed" at home just now in an extraordinary way. Doctors lecture about it, preachers preach on it, daily papers devote their leading columns to the phases of the market, and wherever you turn, tea, in some form or another, catches the eye. The *British Medical Journal* devotes space to discuss the death of a boy, aged seven years, from a shock produced by drinking hot tea without milk. Our medical contemporary writes thus:—"This incident forcibly and sadly emphasizes the particular vice of the ordinary English method of drinking tea. The tea had been left

for some time 'in the oven to warm,' that is to say, it was a strong decoction of tea leaves to which time had been given to extract all the tannin, and which had then been re-warmed. It was then drunk without milk, that is to say, the tannin was not converted into a relative harmless albuminous tannate by the addition of milk. It is precisely because our English method of 'making tea' from such infusion of tannin as well as of theaïne that tea is so injurious to the digestion, and as in this case, when taken in unusual strength into an empty stomach, and without milk, become an irritant poison. No people who know how to make tea use milk with it—neither the Chinese nor the Japanese; but then the hot water (not boiling!) is poured on to and off the leaves at table, and as soon as the liquor becomes of a pale straw colour. The pot is always a small China one, and the hot water kettle is brought alongside it on to table. Half a minute suffices for the first infusion. It is a very grateful and refreshing beverage this 'honourable tea' which one sips at frequent intervals in the Far East; but of course it would be, and is, insipid and not worth drinking if its flavour be drowned by sugar and milk. No people in the world drink so much tea or so often as the Japanese, and Europeans in Japan easily fall into the same habit. No doubt is ever heard of it being injurious or a source of indigestion, that is because they take care not to extract the tannin from the tea leaves, and we take great care to do so. That is why we say persons who live on tea and bread-and-butter have weak digestions, and why this poor boy was poisoned."

A society writer in a weekly paper jerks off those sentences aent this question. "Am not a judge of tea, and as every one was drinking it and discussing it withal, just as if it were some delicate brand of tobacco or famous vintage of champagne, sat quiet and learned a bit as to the respective merits of Indian and China teas. The argument waxed hot, but as a careful listener, am bound to say that after all was said and done, it seemed to me very much as if all the boasted flavour and strength of the rival plants, very much depended on the way it was made. One authority laid down the law that on no account was China tea, which he proclaimed the best, to be allowed to 'draw,' and that a 'cozy' on the tea-pot turned it into a strong poison. This would be flat heresy to my housekeeper, who rather fancies herself as a tea maker, her idea is to pour in the boiling water, pop on the cozy and let the concoction stand. I have not tasted her brew often, but it certainly struck me as strong. I suppose the most harmless way of making tea is that practised by the Russians who give you a pale, straw-coloured beverage in tiny cups. My only use for tea is in the summer, when, if it is iced with a lump of sugar and a large slice of lemon, it is delicious after tennis, a ride or a row." There is no doubt that tea is *par excellence* the *fin de siècle* beverage. High and low, rich and poor, all who aspire to be respectable, turn to the tea-pot for such consolation as liquor can afford, and the consumption increases, and prices keep at a fair level in spite of increased production.—*Madras Times*, Feb. 4th.

TWO NEW YANKEE INVENTIONS.

RAMIE AND LACTITIS.

In the scientific chronicle of the *American Quarterly Catholic Review* is an account of two remarkable inventions, of which we shall hear something more in this country before long. One is the use of ramie fibre as a material for the manufacture of steam pipes. The pipe is made out of ramie fibre, and then subjected to tremendous hydraulic pressure. Under this operation it becomes two and a half times as strong as steel, while remaining comparatively light. It will not absorb moisture, and consequently will not leak. It will neither swell nor shrink, nor rot, nor rust; and for work buried under ground this is another most valuable property sadly lacking in iron and steel. Ramie is a non-conductor of heat. More-

over, ramie, in this hardened condition, is sufficiently incombustible to make it safe for use in steam pipes. Still more remarkable is the other discovery which is announced in the same chronicle, which is to the effect that artificial ivory is to be made, in the future, out of milk:—

The milk is first coagulated as in the process of making cheese. This is then strained and the whey rejected. Ten pounds of the curd is taken and mixed with a solution of three pounds of borax in three quarts of water. This mixture is now placed in a suitable vessel over a slow fire, and left there till it separates into two parts, the one as thin as water, the other rather thicker, somewhat resembling melted gelatine. The watery part is next drawn off and to the residue is added a solution of one pound of a mineral salt in three points of water. Almost any mineral salt will answer; for example, sugar of lead, copperas, blue or white vitriol. This brings about another separation of the mass into a liquid and a unshy solid. The liquid is again got rid of by straining, or better, by filtering. At this point, if desired, colouring matter may be added; if not, the final product will be white. The solid is now subjected to heavy pressure in moulds of any desired shape, and afterwards dried under very great heat. The resulting product, which has been named "lactitis," is very hard and strong. It may be used in the manufacture of a great variety of articles, such as combs, billiard balls, knife handles, penholders—in fine, for almost anything for which bone, ivory, ebonite, or colluloid have heretofore been employed.—*Review of Reviews*.

INTERESTING NOTES FROM THE BAHAMAS.

We extract the following from the proceedings of the Massachusetts Horticultural Society:

On landing at Nassau one was beset by heggars, who, however, form but a small proportion of the whole population. The native negroes are not lazy, if proper incentive is given for exertion. A contractor for canning fruit said that if they understand their tasks they do them as well as anybody; but they have to pare one hundred pineapples to earn three cents, and one thousand is a day's work.

Colonel Wilson was especially interested in the vegetation and horticultural products. The principal growth is acacias, of which there are a great variety. The Royal palm forms a most stately tree. The Banyan grows in perfection in the east part of the group. The Coconut palm thrives as well as in any part of the world and this is the only district near to the United States where it certainly will. They will bear in four years from planting the seed and then fruit perennially, a frond expanding every month, with a cluster of flowers at the base which produces from forty to sixty nuts. They keep growing the whole year and show at all times the whole gamut from flower to ripe fruit; every day the owner can pick fruit, which sell there for three cents apiece. One of the most remarkable trees is the *Bombax Ceiba* or Silk Cotton tree, which braces itself in the rocky soil by enormous buttresses thrown out from the stem.

To understand the agriculture of the islands one must know the conditions of the soil. The people have no idea of anything but limestone, and there is not a plow and hardly a spade in the islands; the implements used in gardening are a crowbar, a sledge hammer and a pickaxe. In a disused quarry the refuse forms, after the pulverizing process has gone on for a long time, and the resulting soil has been mixed with vegetable mould, a good soil for bananas, pineapples, etc. The only exports are sponges, pineapples and Sisal hemp, the latter produced from a species of agave. Formerly oranges were exported, but this has ceased and wonderfully fine ones were bought for fifty cents per hundred. The pineapples are grown mostly on the Island of Eleuthera. The pineapple industry is very interesting. Only the red soil will produce a profitable crop of this fruit, though they can be grown in the

gray soil. The red soil is formed by the decay of red kelp and the gray soil from gray kelp. The industry is necessarily limited in extent on account of the limited area of pineapple lands. This is worth from \$80 to \$100 per acre. In Governor's Harbor, Eleuthera, \$100,000 was distributed among 1,200 people; 300,000 dozen were exported in that collection district, which went mostly to Baltimore and New York. The Red or Cuban variety is preferred for quality and size. They are planted in August and sometimes bear the next year, but sometimes not until eighteen months after planting. The season begins in May, and the product is from 800 to 1,500 dozen per acre. Formerly it was the practice after cropping the land for three or four years to let it come up to bushes or scrub, but now, by the aid of fertilizers, continuous crops are produced. In one district one thousand barrels of fertilizer costing \$7.50 per barrel were used. The plants form thickets with serrated leaves, through which it was impossible for the speaker to go without injury either to person or clothing, but the barefooted negroes passed through them easily and without harm. The fields lie wherever the land is propitious, and the workers go to them in catboats, of which Colonel Wilson had seen thirty-five lying in Governor's Harbor.

The authorities of the island have sought some new industry which should afford employment to laborers where the pineapple cannot be grown. This has been found in the production of Sisal hemp, so called from the *Agave Mexicana*, which grows there as a noxious and persistent weed. It has pale green smooth edged leaves, pointed at the extremity. The leaves are cut off and passed through a machine which crushes them and scrapes off the pulp. There is another species with serrated-edged leaves, which affords a smaller quantity of finer fibre. They must be weeded the first year, after which they will take care of themselves. They are very tenacious of life; one grew after being kept in a tight box for eighteen months. They must not be allowed to "pole"—that is to send up a flower stem. From 400 to 500 plants can be set on an acre, and they will grow higher than a tall man can reach. One man can take care of ten acres. The produce is 800 to 1000 pounds of hemp per acre, being about four per cent of the weight of leaves. Large companies have been formed to pursue this culture, some having acquired 20,000 acres and expended \$80,000 already in improvements, but the government will sell no more land in large tracts, but ten-acre lots can be bought by individuals for \$10 to be paid from the first crop, and it is hoped that the people will become self sustaining. It was pitiful to see women coming with a load of truck on their heads into market, where they pay six pence per day for the privilege of selling their wares; which each spreads on a board or barrel before her, gathered into little groups of the value of a ha'penny or a penny as the case may be, perhaps a single tomato with half an onion, and other things in like proportion. A marketman's sales would not perhaps amount to more than a shilling or two per day. There are few horses in the islands, donkeys being used instead, and their fodder is brought into market in bundles and exposed in the street for sale and firewood the same. The people are obliged and willing to do tedious labor for small returns. They realize that the prosperity of the blockade-running days was a delirium. The price of casual labor is fifty cents per day. Sponge collectors cannot average \$75 per year. The sponges are not agreeable to cure, for the animal matter has to be decomposed. The sponge traffic amounts to \$300,000.—*Florida Dispatch and Fruit-Grower.*

MEAT FOR FOWLS.

It is necessary that fowls in close confinement should have a variety of food, and, as far as possible, a substitute for what they would get if they were at liberty. Grass can be substituted by finely cut hay, sealed clover is best instead of insects; desiccated fish is the next best. Whole grain of different varieties takes the place of wood and grass seed, and for exercise, which is one of the essentials, see that the grain is well

mixed with leaves and trash, so that the fowls will earn by hard work every grain they eat.

Meat food in some form is necessary, and now, that grain is high, I am using less of it and more animal matter. Desiccated fish (the Star brand), bran, clover hay, cut fine, with a little ground grain, is my main dependence.

Our merchant had a supply of seed cow-peas left after the season for planting was over, and I bought them for my fowls. At first they did not take to them kindly, but soon learned to like them and will pick them up first if other grain is thrown to them at the same time. I have never raised cowpeas to gather and shell for feed, but if the yield is anything what it seems to be, I think they would be a profitable crop to raise for poultry. I hope some one will tell us the average yield and the cost of gathering and shelling. We will give the comparative value of peas as food:

Indian corn contains of flesh-forming food 11 per cent.; of mineral substances (bone making food), 1 per cent. Oats, flesh-forming food, 15 per cent., bone-making, 2 per cent. Peas, flesh-forming food, 25 per cent.; bone making, 2 per cent. While oats has 6 per cent. of warmth giving food (oil or fat) corn has 8 per cent., and peas 2 per cent.

The above table shows us peas are more valuable as a food than either corn or oats, and more suited to our warm climate than either oats, wheat or corn.—*Florida Dispatch.*

THE FLORA OF CEYLON.—Many of our readers will share the pleasure with which we learn that the first part of this work, to which Dr. Trimen has devoted so much time, observation and research, is so well advanced that it is likely to be published and be in Ceylon by the commencement of 1893.

THE FOREST DEPARTMENT IN INDIA is happily in the position of returning a large revenue to the State, and by the close of the century it is expected that it will yield a profit of at least a crore of rupees annually. In reviewing the budget estimates of the department for 1891-92 the Government of India note, that the surplus in 1889-90 was nearly 73 lakhs as compared with less than 58 lakhs in the previous year and the average of 40 lakhs in the three years 1886-88. The net revenue which is expected to be realised in the financial year now drawing to a close, is a little under 63 lakhs. This shows a falling-off, but it is only a temporary check, and the decrease is entirely due to one cause—the stagnation in the teak timber trade of Lower Burma, consequent on the fall in prices which occurred four years ago and still influences the market. Moreover the increase in expenditure on account of the re-organisation of the Forest Service amounts to over two lakhs of rupees. In 1889-90 the net profits in Lower Burma were 18 lakhs, and in the Upper Provinces between 15 and 16 lakhs. There can be little doubt that in years to come the figures will be still larger. The reserve from the Madras and Bombay forests shows a steady growth. In the former Presidency it has risen to 41 lakhs as compared with an average of about 27 lakhs for the five years ending with 1889; while in Bombay the increase over the same period is three lakhs. The Andamans are also making good progress. Three years ago the forests in those islands were only profitable to the extent of some sixteen thousand rupees. Now they contribute one and a quarter lakhs to the revenue. The department is essentially one in which the expenditure should be generous, and with the handsome surplus which it yields annually, the Government can afford to carry out the projects suggested last year by the Inspector-General. The chief of these is the improvement of communications, and it would be well if special grants were sanctioned for the next few years in making roads to forests which are more or less landlocked.—*Pioneer.*

FIVE YEARS' TEA YIELD ON A MATALE ESTATE.

STATEMENT of made Tea secured, yield in lb. for year ending 31st December 1891, on ----- Estate, Matale, with comparative yield per acre for years 1887, 1888, 1889 and 1890.

THE YATIYANTOTA TEA COMPANY, LIMITED.

The following is the Report of the directors presented at the annual ordinary general meeting of the shareholders held at noon today:—

The Directors have pleasure in submitting to the Shareholders the Accounts of the Company for 1891.

The weather during the past year was unusually favourable for the growth of Tea in all stages and the yield has largely exceeded the estimated quantity, the total crop being 252,874 lb of made Tea, or an average of 625 lb per acre. The clearing of 30 acres referred to in the last Report proceeds well and the clearing of 54 acres planted in 1890 has been successfully supplied. The latter will, from the beginning of this year, be treated as part of the Estate in being, although very little leaf can be expected from it in the current season.

The whole crop has been sold locally at an average net price of 43 cent per lb, which the Directors consider satisfactory in view of the low range of tea prices which obtained during the greater part of last year. Allowing for the expense of manufacturing 22,070 lb. Tea for a neighbouring estate, the cost of laying down the tea in Colombo was 20 cents per lb. After making the usual provision for depreciation of buildings and machinery, the net balance of profit for the year available for dividend is Rs1,446 96 equal to 57 per cent of the paid up capital of the Company. Of this sum Rs18,000 has been absorbed in paying an interim dividend of 20 per cent and the Directors propose that a further dividend of 20 per cent be declared and made payable on the 15th February, and that the sum of Rs13,500 (15 per cent) be added to the Extension Fund. A balance of Rs1,946 96 will then remain to be carried forward to next year's account.

In proposing to reserve so large a proportion of the profits, the Directors have in view the cost of additional withering accommodation and machinery, necessary for the increasing requirements of the Estate, and of the Company's share of contribution towards the construction of a grant-in-aid road to the Estate. This contribution viz: Rs5,534 85, has been paid to Government since the end of last year and it is hoped that no delay will take place in the construction of the road, the early completion of which will be of immense benefit to the Estate. The Directors have also decided upon opening this year and planting with Tea further 33 acres of Poltagama and 48 acres of the Abamalla block, for which purpose first-class seed has already been provided. These additions will bring up the cultivated acreage of the properties to 569 acres.

In view of the past season having been so favourable for the yield of tea, the directors can hardly

expect an increased quantity in the current year and prefer basing their calculation at the same rate per acre. The estimate is therefore put down as 250,000 lbs. tea, against an estimated expenditure on the estate of R50,000.

In terms of the Articles of Association, Mr. W. D. Gibbon retires by rotation from the office of Director but, being eligible, offers himself for re-election.

The appointment of an Auditor for the current year will rest with the meeting.

By order of the Directors,
G. W. CARLYON,
Secretary.

Colombo, 26th Jan. 1892.

THE WE-OYA TEA COMPANY, LIMITED.

The following is the report of the Directors presented at the Annual Ordinary General Meeting of the Shareholders held at 3 p.m. today:—

The Directors have pleasure in submitting to the Shareholders the Accounts of the Company for the past year.

The total Tea crop was 50,175 lb being 10 175 lb. in excess of the estimate, and realized R21,197-89 or an average net price of 42½ cents per lb. against an expenditure of R15 520-91, equal to 31 cents per lb.

The profit on the year's working is equal to about 6½ per cent on the Capital of the Company and after writing off the old balance at debit of Profit and Loss, a credit balance is shown of R1,712-73 which the Directors propose to carry forward.

The Factory was completed in August and 28,105 lb. of tea were manufactured in it during the last five months of the year.

Since the issue of the Company's last report it was found advisable to increase the size of the Factory and to add to the Machinery; the expenditure under these heads is therefore larger than was anticipated but it is expected that all necessary manufacturing arrangements for some years have now been met.

The estimated expenditure for the present year is 19,550 on 85,000 lb. of Tea and R3,550 to plant further 29 acres with Tea and to build more lines. With the new clearing referred to, the cultivated acreage of the Estate will be 248 acres. The 219 acres planted in 1888-1890, which will all be in bearing this year, now show a very fine cover of Tea.

The Directors regret that in the clearing of 1890 owing to a false boundary, a mistake was made whereby 15 acres belonging to Ederapolla Estate were filled and planted in Tea by the Company. The mistake was discovered in February 1891 and the land was restored to Ederapolla, from the proprietors of which the Company hope to be recouped their expenditure. A small payment in part compensation has been made and legal steps have been taken to recover the balance claimed, viz. R1,150.

In terms of the Articles of the Association, Mr. W. J. Smith now retires from the office of Director but, being eligible, offers himself for re-election. The election of a fourth Director and of an Auditor for the current year will rest with the Meeting.

By order of the Directors,
G. W. CARLYON, Secy.

Colombo, 26th Jan. 1892.

CINCHONA FROM RÉUNION.—Although it has long been known that some of the planters in the Island of Réunion, near Mauritius, were experimenting in cinchona cultivation, no bark from that part of the world has as yet appeared upon the market. It now transpires, however, that samples of Réunion cinchona have lately been analysed by M. Houdas, of the Paris School of Pharmacy, and found to contain 1.70 per cent. of quinine (=229 per cent of sulphate of quinine), in a total of 4.32 per cent. of alkaloids. M. Houdas advises the planters not to pursue the cultivation at present.—*Chemist and Druggist*, Jan. 23rd.

AMSTERDAM BARK-HOLDERS WANT TO SELL.—In connection with the large quantity of cinchona which will be offered for sale in Amsterdam on February 25th, our correspondent there points out that of the 4,780 packages in the catalogue no less than 1,158 are of old import and belong to owners who want to seize the opportunity to profit, if they can, by the improved tendency of the market. The fact also deserves attention that at the forthcoming auctions 327 packages (equivalent to 28,000 oz. quinine sulphate) of bark from the Dsjagiri and Soekawana plantations will be offered. This is the first time for several years that this bark, which used to be consigned direct to the Brunswick factory, appears in the open market.—*Chemist and Druggist*.

THE FINAL DRYING OF TEA FOR PACKING is thus discussed by the London correspondent of the *Indian Planters' Gazette*:—

There are some here, now strongly preaching the doctrine that the reason why teas do not keep as of old, lies in the method of rapid firing for "pucca batio" which the introduction of Dryers has brought about. They point out that when tea was "final fired" by remaining all night upon warm *chulahs* or *dhools*, one never, or very seldom, heard complaints of teas not keeping. Whilst they acknowledge the immense amount of room etc., that would be required to final fire so slowly now, with the immense output of today on some estates they maintain that the quality would, by the improvement effected, repay the extra hoose-room and labour; and that the expense of these items should not stand in the way of pence per lb. put on the value of the produce. I only call preliminary attention to this doctrine now, just to record its birth; but it will not be the last word heard about it. Reasons are given, of course, to justify it. Some may feel tempted to put the question to the test this next season, that they may be the first to benefit by it, should it prove to be well-founded. One "break" might show as some index as to effect on quality, though it would not, unless held for months, show the precise effect upon the keeping quality. Of course, this trial "break" to be of any value as a test, would require a sister break final fired on modern principles, out of the same bulk of tea. If anyone is tempted to make the trial, I will, if requested, take samples of the two breaks to a dozen firms of brokers and publish the reports here, *pro bono publico*.

THE KINDS OF CACAO.—We give prominence to the following remarks on this question by Dr. Trimen:—

Mr Hart of Trinidad in a paper on the nomenclature of cacao (as reprinted in *Tropical Agriculturist* for Jan. 1892 from the "Agricultural Record") take me to task for translating (in my report for 1890) "C. lillo," by "wild." He does not however show me to be wrong in so doing, but merely suggests as a fitter rendering the word "native." This is perhaps a better equivalent, but I wish to point out that it is precisely what I intended to convey by the word "wild," and that I have made no error in this matter. I am disappointed to find that Mr. Hart supplies no data towards determining the interesting question as to which of the two cultivated strains is the nearer in the original uncultivated *T. cacao*. It should surely be possible to settle this in the West; here of course we are helpless in the matter. Mr Hart seems to have been much impressed by the record in my report of the opinion of a large Ceylon grower of forests of cacao that it is here gradually acquiring the characters of the old Ceylon sort; and he appears to jump to the conclusion that *erillo* must therefore be the "original type," to which a reversion is taking place. But in my report I took care to point out, and I now do so again, that many more years' experience, and many more accurate observations will be required to establish as an actual fact, the suggestive observation referred to, and it is, in my opinion, premature to base any argument upon it at present.—HENRY TRIMEN, *Peradeniya*, Feb. 8th.

COFFEE AND TEA IN THE UNITED STATES.

Were we writing about Britain we should have to reverse the order of the two great beverages of the breakfast table. But coffee is by far the greater favourite in the United States, and its consumption has progressed enormously, while that of tea has scarcely shown any increase for years back. And the teas which are consumed owe their origin to China and Japan, mainly to the latter country. Of so little account as yet are the teas of India and Ceylon held, or such is the prejudice of leaders against them, that in a "Review of Prices for 1891" in the *American Grocer* neither receives mention. In the case of coffee low prices had led to greatly increased consumption, the value of the imports for the year ending June 1891 being \$96,123,000 against an average of \$62,504,000 for the previous five years, and actual figures for 1886 of only \$42,672,000. Prime Rio was in that year down to 10-76 cents, while the year after the price went up to 18 cents of a dollar, of course. The imports, less exports in the year ended June 1891, reached the enormous figure of 511,041,000 lb.

When we came to tea we get very different figures, figures which have varied but little for a dozen years. The imports in 1891 were only 83,453,000 lb. valued at \$13,839,000, against 83,886,000 valued at \$12,317,000 the previous year. So that over half a million pounds of coffee to eighty-three millions of pounds of tea are consumed in the United States. The population is about 65 millions, so that tea in comparison with coffee in America holds a position not very much more favourable than that of coffee in comparison with tea in Great Britain. In the ten months subsequent to June 1891 the imports of tea had actually shown a decrease of more than five millions of pounds when compared with the corresponding period of 1890. The average prices of tea are not very much higher than those of coffee. On each recurring occasion of our noticing the figures for the consumption of coffee and tea in the United States, the more formidable do the difficulties appear of those who are trying to introduce Ceylon tea to the American markets. They have not only to displace the inferior teas which are now favourites, but to contend with a taste which is every year more pronounced in favour of coffee. We hope much, however, from the judicious representation of our product to be made at the Chicago Exhibition, in the absolute necessity of which we still believe, because we believe in crops which present outlets cannot by any means fully absorb.—The following are the remarks in the *American Grocer* :—

COFFEE.

For the first time since 1888 the consumption rises beyond the figures for that year. Coffee has declined during the year, and now rules on Brazil sorts 2½ at 4 cents below the prices of one year ago. Through out the year spot stocks have been light. Coffee, when judged by the value of the imports, constitutes 11.33 per cent of the total imports of foreign merchandise. The value of the imports for the fiscal year ending June 30, 1891, was \$96,123,777, against a yearly average for the preceding five years of \$62,504,096, an increase of \$33,619,681. In 1886 the imports were valued at less than one-half the value in 1891, being \$42,672,937. That was a year of low prices, the average cost of fair to prime Rio being 10.76 cents. The next year marked the beginning of an era of high cost, the average rising to 18.11 cents for the same grade. This year marks another change toward a basis of lower figures and undoubtedly a steady increase in consumption.

The imports into the United States for the year ending June 30, 1891, less exports, compare with the preceding year as follows:

	1891.	1890.
	Pounds.	Pounds.
Imports less exports ..	511,041,459	490,161,900

The consumption for the year ending Dec. 31, 1891, at six ports was 233,058 tons, against 209,45, tons in 1890, a gain of 23,601 tons, or 11.2 per cent, which, under normal conditions, is above the average annual increase in consumption.

The average monthly cost of leading varieties of coffee, and the average for the year, are shown in the following table:

	Rio, No. 7.	Rio, No. 3	Marscaibo.	Padang, mats.
Jan. ...	17-43	19-23	19-05 at 22-90	33-10 at 24-40

Average,				
1891..	16-45	18-15	18-05 at 20-91	24-51 at 25-64

During several months of the past year there has been a great scarcity of desirable grades of Rio coffee so that Fair or No. 3, and at times grades below No. 7 and above No. 3 have commanded a premium varying from ¼ to 3 cents per pound above the basis of Exchange quotations and the established difference between grades.

While the above table shows a decline of 4 cents in Brazil coffee, the average annual cost is only 1½ cents per pound less than in 1890, when it was 19.64 cents for Fair (No. 3) Rio; in 1889, 18.55 cents; in 1888, 15.35 cents; in 1887, 17.80 cents; in 1886, 10.32 cents; in 1885, 9.01 cents.

The sales on the Coffee Exchange during 1891 were 7,738,000 bags, against 9,733,000 bags in 1890.

TEA.

The imports of tea for the year ending June 30th 1891 were 83,453,339 pounds, valued at \$13,828,993, against 83,886,829 pounds, valued at \$12,317,493 for the preceding year.

For the ten months of the calendar year ending Oct. 31st, 1891, the imports were 65,235,080 pounds, valued at \$10,447,252, against 70,916,020 pounds, valued at \$10,761,723 for the corresponding period in 1890.

It will be noted that while the average declared value of tea imported during the fiscal year ending June 30th, 1891, was 17 cents at port of shipment, being 2 cents per pound higher than in 1890, the average cost of medium Japan in the New York market was 1½ cents per pound lower in 1891 than in 1890, while superior Formosa varied only one-third of a cent per pound from the average of the previous year.

The following table exhibits the average import price at the point of exportation as compared with preceding years:

Years—	Cents
1891 ...	17.
1890 ...	15.
1889 ...	15-9
1888 ...	15.8
1887 ...	18.7
1886 ...	19.6

The following table shows the average monthly

At the close of 1890 the tea market was unsettled and weak, attributed to auction-room sales, cheap silver and dear money. In January Formosa Oolongs improved in price—fully 3 at 4 cents higher for invoices; Amoy 2 cents for fair to good; Foochows, 2 at 3 cents. In February and March a weak tone prevailed. Pingsay improved in April, while weakness characterized the trade in Oolongs. In June new crop Japans arrived via Pacific coast. Extra fine teas by first steamer sold at 34 at 42 cents for choice to extra choicest. In July Japans were weak and declining; greens steady; Formosa pressed for sale. New crop arrived and was sold at an average of nearly 27 cents for good to superior, being 20 per cent above cost of old crop of like grade. Toward the close of August old crop Formosa was reduced to a small supply. In September free receipts of new crop Formosa sold on a basis of 24 at 25 cents for superior. New crop country greens sold at 19½ cents for fine Foochow; fine to finest Moyunc, 23½ at 28 cents. In October there was a decline in Formosa, due to free offerings. During November and December there was a steady market.

DUNKELD ESTATE COMPANY, LIMITED.

The first annual ordinary general meeting of the Shareholders, of this company was held in Colombo at 2 p.m. yesterday, when the following report by the Directors was submitted and adopted:—

The Directors have pleasure in submitting to the Shareholders the accounts of the Company for the eight months ending 31st December, 1891.

The total Tea crop was 89,435 lb., which realised R11,560.84 (against an estimated yield of 80,000 lb. to realize R10,000.) equal to an average net price of 46½ cents per lb.; whilst the expenditure on the Estate, including transport to Colombo, was 27½ cents per lb.

After transferring R1,466.56 to a special fund to provide for depreciation of buildings and machinery and writing off the preliminary expenses incidental to the formation of the Company, the net profit available for dividend is R11,950.24, equal to 12½ per cent. per annum on the paid up capital of the Company. The Directors propose that a dividend for the eight months of 8 per cent., absorbing R11,200, be declared and made payable on the 15th February, and that the balance of R750.24 be carried forward, which they trust will meet the approval of Shareholders. Since the purchase of the Estate considerable additions to the buildings and machinery have been made, and steps are being taken to improve and extend the withering accommodation. When these arrangements have been completed it is expected that the Factory will be fully capable of meeting the requirements of the estate for some years to come. About 40 acres of reserve land have been successfully planted in tea during the eight months, and about 8 acres more will be planted this year, when the total cultivated acreage will be 382 acres.

The Tea crop in 1892 is estimated at 150,000 lb., to cost, laid down in Colombo, R38,625, equal to 25½ cents per lb. The expenditure on capital account to

complete the Factory and for new clearings is estimated at R8,000, but of this R2,000 may not be required until 1893.

In terms of the Articles of Association all the Directors now retire, but, being eligible, offer themselves for re-election.

The appointment of an Auditor for the current year will rest with the meeting.

By order of the Directors,
G. W. CARLYON,
Secretary.

Colombo, 29th January, 1892.

THE GLASGOW ESTATE CO., LIMITED.

The following is the report of the Directors presented at the first annual ordinary general meeting of the shareholders, held at 4 p.m. yesterday:—

The Directors having decided to make the financial year of the Company run from 1st January to 31st December, accounts have been made up for the two months ending 31st December last, and are now presented to the shareholders.

The produce obtained in this period has realized good prices, the average for 13,436 lb. Tea being over 61 cents per lb., and for 418½ bushels coffee over R14.50 per bushel. The result of the two months' working is a net profit of R6,217.83, after placing R316.66 to a fund to provide for depreciation of buildings and machinery and writing off the expenses of forming the Company.

This profit would admit of a dividend at the rate of 8 per cent. per annum; but as the profits from Coffee were obtained to a great extent from expenditure incurred before the Company took over the estate, the Directors propose that a dividend of 1½ per cent. only be declared (being at the rate of 9 per cent. per annum,) and that R1,800 be placed to the credit of an extension fund, leaving R4,417.83 to be carried forward to the next account.

To meet the increasing requirements of the estate extensions to the Factory and additions to machinery and to line accommodation are necessary. The sum of R6,108 has been estimated for under these heads in the present year.

Arrangements have been made to plant this year with 40 acres of land now under coffee, the cost of which is estimated at R1,885.

The estimate of expenditure on working account in 1892 is R32,780.30 against 82,000 lb. Tea, 1,300 bushels Coffee, and 12,000 lb. Cinchona Bark. It will be understood that no reliable estimate of the Coffee Crop can be made so early in the year, and that the realization of the estimate depends greatly on weather and other circumstances; whilst in harvesting Cinchona Bark the Directors will be guided by the state of a market.

In terms of the Articles of Association the present Directors now retire from office, but, being eligible, offer themselves for re-election.

The appointment of an Auditor for the current year will rest with the meeting.

By order of the Directors,
G. W. CARLYON,
Secretary.

Colombo, 29th Jan. 1892.

The richness in the resinous active principle of the jalap tubers cultivated on the Dodabotta plantations compared with those obtained from Mexico is said to be superior, and it is surprising although the Nilgiris are eminently adapted for the cultivation of jalap that no private plantors have taken up the propagation of a drug which would lead to a profitable industry. The Ipeacuhana root too is growing well in the Wynaad. Mr. Hooper some time ago analysed a sample from a plant only two years old and found it to contain as much emetine as if found in the commercial drug.—S. of I. Observer, Jan. 16th.

NOTES FROM THE ADMINISTRATION
REPORT OF THE MADRAS PRESI-
DENCY FOR 1891-92.

GOVERNMENT HORTICULTURE.—The season was favourable for the year growth of plants. The rainfall for the year at the Government Gardens, Ootacamund, was 48.61 inches and the condition of the Gardens continued to improve both as regards neatness and the development of plants and shrubs, though the number of new plants introduced during the year was comparatively small. Stonehouse park and Church Hill park were carefully conserved, and the Crewe Hall and Ottley Hall estates were leased for the cultivation of potatoes. Sim's Park at Coonoor, was kept in excellent order and several improvements made to it. The trees in the shola grew rapidly but the severe frost in the winter seriously affected the terminal shoots and destroyed most of them. The success of the Burliyar Experimental Gardens was very noticeable and several new specimens were added. The Durian continued its rapid growth reaching a height of 42 feet. The Liberian coffee yielded a fair crop and was proof to the navages of leaf disease, but the Mangostine crop was not a good one. Several new specimens were planted in the Gudalur experimental Gardens, but the want of rain and the depredations of wild animals were serious obstacles to the success of these gardens. Considerable additions were made to the Herbarium and some Botanical works of value were added to Library. The receipts for the year amounted to Rs.4,296 and the expenditure to Rs.22,531. Seeds and plants to the value of Rs.585 were distributed gratis or in exchange for gifts made to the gardens. The Government Quinologist made several analyses of the tobacco leaves grown from the seeds sown last year, the result proving that the tobacco was of good composition.

GOVERNMENT CINCHONA.—The climatic conditions of the season on the Nilgiris were not altogether unfavorable to the growth of Cinchona, the South-west monsoon was unusually dry especially on the western side of the plateau and the fall of frost was comparatively mild, but the very old and very young trees did not thrive. The rainfall on the "Dodabetta" Estate was 48.13 inches, on the "Naduvatom" Estate 69.58 inches, on the "Hooker" Estate 60.79 inches and on the "Wood" Estate 46.92 inches, in every case below the average of previous years. About 100 acres were newly trenched and manured and a considerable amount of replanting done on the "Dodabetta" and "Naduvatom" Estates, and on the "Hooker" and "Wood" Estates in Pykara, a number of trees were coppiced owing to their showing signs of decay, the Succirabras on the "Wood" Estate having undergone this process a second time. The nurseries had a plentiful stock of seedlings and balled plants, but there was considerable mortality among the latter due to various causes which should have been avoided. The out-turn of bark harvested during the year was 133,351 lb., and of quinine manufactured at the factory 2,928 lb, besides 1,050 lb. of febrifuge. The actual receipts for the year amounted to Rs.28,876 and the expenditure to Rs.74,914. This does not include the value of quinine supplied to Collectors of districts and bark to Messrs. Kemp and Co., nor that of quinine and febrifuge in stock. These are estimated at Rs.11,679. The results of the analytical work done by the Government Quinologist are satisfactory and go to prove that the sulphate of quinine produced is of standard quality and the febrifuge of uniform composition.

EXOTICS.—The cultivation of mahogany was

carried on in the Nilgiris; the trees were attacked by borers in some parts of this district as well as in Malabar. There was a decrease in the number of trees, chiefly eucalyptus and acacia felled during the year and there was an applicable fall in the revenue under the head of Forest produce. Charcoal burning was carried on with the aid of some newly imported Morean's Kilns.—*South of India Observer.*

FROM THE METROPOLIS.

TEA-DRYING AND GENERAL PREPARATION
IN INDIA:

NO TRUTH IN THE STORY THAT DAVIDSON'S "SIROCCOS"
HAD BEEN LAID ON ONE SIDE BY A "PRINCELY"
CALCUTTA TEA FIRM;
QUITE THE REVERSE: MORE BEING ORDERED.

LONDON, Jan. 29th.

My brief "City" letter to you published in *Observer* of the 4th inst., in referring to improved tea machinery, gave currency to a story about an alleged failure of Mr. Davidson's well-known "Siroccos" to give satisfaction in a very large North Indian tea factory. I told "the tale as 't was told to me," but with qualifications and with the expression of a certainty that there must be another side to the story which you would quickly hear from Mr. Davidson or his representatives. I was under the impression, when I wrote, that Mr. Davidson would be probably back in Ceylon from Calcutta, about the time my letter reached you. But instead I find that after the completion of his visit and work in the Indian tea districts and a visit to Ceylon, he returned home in October last.

I have had today, for the first time, the pleasure of meeting Mr. Davidson, and have received information which shows me that there is a most decidedly negative other side to the "City" story about the "Siroccos," inasmuch as—to put the matter at once in its briefest and most telling form—not a single Sirocco has failed to give satisfaction to, or has been discarded by, the "princely" tea firm in Calcutta referred to. It is most extraordinary how from an extremely slender basis of fact, which has been made clear to me (and which has nothing to do with the "Siroccos"), so distorted and unreliable a statement got put forward at this end. I had no sooner learned the exact state of the case from Mr. Davidson and realized his very natural annoyance than I decided, in case his agent had not made a local correction, to send you the "special telegram" which you will this day receive. Both the telegram and letter with the notice attracted to the subject will do good in controverting mistaken views which might otherwise, if the story had not been noticed at all, become generally talked of and accepted. I feel, more especially after the courteous way in which Mr. Davidson personally gave the Ceylon press and planters the benefit of his experience during his recent visit to the island, and the ready way in which he answered all my questions and gave information which he might well have refused, that a very full correction of the letter of January 4th and the *amende honorable* are due to the enterprising Belfast Tea Machinist and inventor, who has done so much to lay the planters of India and Ceylon under obligation to him—not only for his machinery, and primarily the "Siroccos," but also for his really extensive work in making Indian teas known to, and appreciated by, the British public at a time when the struggle against China teas was a very uphill one. I may mention, indeed, that he also was one of the first to make a big

attempt in America and on the Continent of Europe to promote the use of Indian teas. Mr. Davidson, as you know, paid a visit of several months' duration last year to the Indian tea districts. This was mainly in connection with the interests of a tea company commanding an annual output of probably about ten million lb of tea. He had to deal not with one central factory, but with several factories in advising and directing the re-arrangement and simplification of the working and machinery, so that now the chief factories referred to are among the most admirable and complete in this tea-growing world. It is true that some time ago the company decided on amplifying their drying power by a large addition of the well-known "Down-Draft Siroccos;" but it is not true that any of these "Siroccos" have since been discarded and replaced by other Driers. What happened was this:—Mr. Davidson went out with full power to place the factories in a state of proper equipment and working, and in doing so had to arrange for new steam engines, shafting, &c., including an additional supply of Jackson's "Rollers." He found, moreover, that notwithstanding all the "Siroccos" at work there was a deficiency in drying capacity, and he himself arranged for a majority of the other "Driers" being again utilized, in new and more convenient positions, by no means as substitutes, but as additions to the "Siroccos." It is obvious that the story of the large expenditure incurred would have a very different appearance if it were known that new steam engines, shafting, rollers, Blackman fans, as well as other machinery and a large amount of new work and re-arrangement were included.

But there is more to explain and correct: the statement of an average falling-off of 4d in the value of the tea turned out by the "Siroccos" is entirely a mistake. In the first place, the "Siroccos" had nothing to do with a novel experiment made by the company at the instance of Mr. Davidson, in preparing the teas referred to, and the result was not a falling-off on the usual average in London. This experiment was based on a new machine entirely distinct from the "Siroccos" and in fact operating more in connection with the "rolling" and "fermenting" departments of preparation. The object indeed is to check "fermentation." Well, a considerable number of these new machines had been put in use, and the result was most satisfactory according to the judgment of Calcutta tea experts inasmuch as they valued the teas so turned out for their improved flavour, at 2d to 4d per lb. above the teas prepared in the old fashion; but when these teas prepared of a new fashion and with a rather novel preparation got to London, the experts and trade here were not prepared to substantiate the Calcutta valuation,—that in fact they only realized much the same average as the ordinary teas, and that it was at once recognised, a new article, as this preparation amounted to, must only be introduced gradually to the trade and not all at once in large quantities. It is clear, however, that there has been no falling-off of 4d on the ordinary averages, but only as compared with the enhanced Calcutta valuation—a very different thing. However, the company decided not to go on with the new preparation for about two-thirds of their tea; but in respect of the rest it is still being tried and the machines are at work. By degrees, therefore, the new system will have a fair trial and the teas so prepared can be more thoroughly tested, according to the varying taste of the trade and consumers.

So much for the true account of Mr. Davidson's mission and its results so far, to the factories of one of the largest tea companies in India,

A NEW TEA MACHINERY DEPÔT IN COLOMBO.

But you and the tea planters of Ceylon will be further glad to learn that Mr. Davidson, having decided during his visit to the island to open a Machinery Depôt and show-room on an adequate scale in Colombo, has purchased for this purpose the Suduwella Mills from Messrs. Mackwood & Co. These planters and merchants will soon be able to see for themselves the various machines with which Mr. Davidson's name is identified, in every size and variety and in working order. These, I understand, will include a very admirable and economical sorting machine. Repairs will also be promptly attended to at the same depôt—I was going to add "renewals" as well, but have been reminded that the word would be out of the place, after the exhibition of the "stove" of the Elbedde Down-Draft machine—the first ever erected in Colombo after three years' service, without the least of wear and tear visible, beyond the soot.

NEW "PRICE LIST."

Finally Mr. Davidson has placed at our service copies of his latest circular-catalogue (one of which I send you) very nicely got up with illustrations of the various forms of "Sirocco" manufactured by him in his Belfast Engineering Establishment. Prices and testimonials and descriptive details are given, as also, in a supplement, a series of latest improvements easily applicable to machines already in use, such as "Damper Valve in Fan Exhaust," "Baffle Plate in Air Duct," and "Wire Web Screen." One of the most interesting engravings in the catalogue is from a sketch by Mr. Davidson himself and exhibits the "Old (Chinese) methods of drying tea over charcoal fires," the coolies and chulas being conspicuous. A spray of the tea bush, leaves, flush and flower form a border. It speaks volumes for the esteem in which "Siroccos" are held that this list is able to report over 2,500 now in use.

It is evident from all here recorded that if there be enterprise evident in other directions among tea machinists—as I mentioned in my letter of the 4th—there is not the least abatement, but rather an advance on the part of the gentleman of "Sirocco" and Belfast fame; and it is very satisfactory to find the growing importance of the Ceylon tea industry so fully recognized.

PERU AND THE "COMMISSIONERS."

IN THE WEST INDIES: JAMAICA, GRENADA AND TRINIDAD.

In my last I omitted to give you the news brought back by Messrs. Sinclair and Ross from the Far West and South. I was only able to see the letter after the previous mail had left and was sorry to find him enduring the tail-end of a cold and ague attack which developed after a very severe fashion in the West Indies. On the other hand Mr. Sinclair, whom I met the same night at King's Cross, en route from Southampton to Scotland (Mr. Ross had landed at Plymouth), looked very well and not at all the emaciated invalid I had anticipated. Indeed, the "corporation" was almost intact and the little difference I saw was all in favour of activity and vigour. It is strange that while one Commissioner should suffer on the Andes, the attack on the latter should only come on severely in passing from Jamaica or Barbadoes to Grenada and Trinidad. About the results of their mission to Peru, both Commissioners are properly reticent until their reports are formally presented at headquarters. This will probably take place early in February; but meantime enough is known to show that both gentlemen think very highly of large extents of

the country inspected, for settlement and planting purposes. The climate is splendid; the soil in many parts very good; the rainfall sufficient. The two great points are in respect of "labour supply" and "transport." For the former, the inclination is to recommend Indian coolies; but if any difficulty is made about these, there are the Chinese—many of whom work well in the country already—to fall back on, and they can be got under indentures in large numbers. Very few planting countries in the world would begin so favourably for "transport" as Peru. Apart from the many railway lines already opened, there are several important extensions now under construction—notably the line across the Andes, which will shortly be opened and will prove of immense advantage. Both gentlemen, however, I found inclined, as true patriots, that after all there was no place equal to Ceylon! I had to remark, however, that they were not so young as they were, and it was natural they should revert to the scene of the labours of their youth and manhood, as the first spot on the earth, &c.; but that they should try to think of how Peru would seem to them if they were still as fit for pioneering work and beginning a new enterprise as they were in the "fifties" and "sixties." Apart from the railways in Peru, for planters in the eastern slopes and valleys, there will be an outlet by water down tributaries to the Amazon, up which for long distances, steamers now voyage.

It was interesting to hear of the West Indian islands visited on the return voyage. Mr. Sinclair has never seen a people outwardly better off or more contented with their lot than the cultivating negroes of Jamaica with their little farms or gardons. Mr. Ross paid a visit to Mr. W. Sabonadière and had a most hearty reception. Driving 12 miles to Gordon's Town, he there found (arranged by telephone) mules ready to carry him 10 miles up into the hills by a first-class bridle road to Mr. Sabonadière's estate. He arrived at the bungalow as evening had closed in and naturally shouted "Boy!" An intelligent negress servant answered the call, wishing to know in fair English "what name to give to master?" Miss Sabonadière was away from home; but the host made the evening very pleasant for his guest and there was much talk about the dear old isle in the Eastern Seas which it is a pity Mr. Sabonadière ever left, though his coffee is doing very well on his Jamaica plantation about 2,500 ft. above sea-level, equal to 3,500 ft. in Ceylon.

Perhaps Grenada was the island which most attracted the visitors for its beauty and resources. [It is the island whose beauties Mr. D. Morris chiefly depicted in his recent lecture.] Mr. Ross had a letter of introduction to the Governor from his brother, and both visitors were very kindly received. They heard of, though they did not meet, C. H. A. Ross, formerly of Ceylon, and how he was doing well. They also travelled to Trinidad with the Hon. Mr. Alexander of Grenada, who bore so strong a resemblance to his near relative, Mr. W. H. G. Duncan of Colombo, that Mr. Ross made sure he had seen him in Ceylon, where, however, he has never been. At Trinidad, a good deal of attention was given to cacao, and one of the oldest and most important plantations—San Antonio—whose "cocoa" was held up as a model (an ideal) to Mr. Ross when he commenced work in Malacca with the new product. And before he left off (and now) Ceylon "cocoa" secures 40 to 50 per cent better prices than San Antonio. A great deal is due to the very primitive style of cultivation and preparation followed in Trinidad. Even on San Antonio, such a thing as weeding or clean cultivation

in the Ceylon sense, is unknown; while the so-called factory and preparation were of the most primitive. Covering with clay must be kept up to prevent mouldiness. "Why if a planter in Ceylon was in the habit of allowing his cocoa become mouldy, he would probably lose his place," was the natural remark. Among the few negroes crowding round the masters in the "factory" in free and easy style, was one Tamil, and no one ever was more astonished than he when he got a mouthful of his own tongue from Mr. Ross. He removed his cap and stood attention at once!—and it turned out that Mr. G. A. Dick had been his old Ceylon "Durai" and how surprised was he to learn that even in Udapussellawa—on Ragalla—coffee was just giving way to tea. Mr. Hart of the Botanic Gardens was very pleased to see the visitors and to show them his "cacao" trees, but the favourite Ceylon kind—to his astonishment—Mr. Hart learned, did not appear amongst them. The fact is that the Trinidad folk discarded the finer but more delicate Forastero kind long ago, just as the Ceylon planters of recent years have been doing. A remark made about "hybridizing," on the part of one of the visitors showed how Ceylon planters in contradistinction to most in the West, study their profession. The conclusion arrived at was that cacao in Ceylon at five years old—in consequence of the more careful cultivation—is as far advanced as at eight years in the West Indies, notwithstanding better soil.

NOTES ON PRODUCE AND FINANCE.

EVERY TEA RETAILER HIS OWN GROWER.—A correspondent of the *Grocer*, whose communication to the effect that tea-retailing and tea planting were particularly useful in combination, was referred to in our issue of the 15th, again writes to that journal on this subject. He says:—"I find that the suggestion contained in my letter that a retail tea-dealer could to his benefit place himself in direct contact with tea plantations, has been the subject of an article by the editor of the *Home and Colonial Mail*. Naturally, the gist of the article is to scout the idea, and I trust, therefore, you will give me an opportunity to inform him that my knowledge on the subject is a little more than superficial. In my letter I pointed out that the only Ceylon company of importance that had been launched paid dividends at the rate of 15 per cent, and I asked the question, why, with such brilliant results, plantations should not be owned and managed by a combination of retail traders in the form of a limited company, thus saving not only the wholesale dealer's profit, but also that of the planters? What are the requirements to compass success? A good manager of the plantations, and a good manager to supervise the distribution in London, with a board of directors. This being so, may I ask what is the difference between a good manager in Ceylon and London with well-paid individuals as directors, and a good manager in Ceylon and London with a directorate of retail traders who would give their time with very little remuneration because it is their interest to do so? My contention is that retailers with efficient managers, which they are just as able to select as any other body of men, can manage a company more economically than the ordinary director. But the article—as a terrible warning—that suggests that before embarking the grocer in such a venture I should get the opinion of the retail trader who has tried it, and ascertain whether it has paid. Inasmuch that I very much admire the practical shrewdness if the gentleman alluded to, I need not hesitate

to mention his name. In my opinion, the ordinary retail tea-dealer must, in the management of his tea trade, stand aside to Mr. Lipton, and continue to do so until he finds out the strength of his argument. The substance of what Mr. Lipton says to the public is this:—"I am the owner of certain tea estates, from which I derive my produce without the intervention of any persons—except, of course, his managers in Ceylon and London—and I therefore am in a position to supply you (the public) better than anyone else, because the traders who now supply you do not buy from a plantation, and therefore purchase from other sources in which there must be middlemen's profit." The argument is overwhelming to a public whose duties in the struggle for life will not permit them to enter into the pros and cons, and thus the day is gained. The whole question is one to be gauged by the grocer who is up to date; and he will at once see the advantage, for trading purposes, of being a part proprietor of plantations from which he can obtain, without being tied, as much or as little of his tea direct, without any intermediate expenses, show his customers views of the plantations in which he is interested, and other evidences of his strong position and the special attention he gives this particular paying article."

QUITTING A MISTAKE.—This correspondent is in error if he supposes that we have scouted the idea that no tea gardens, the property of tea retailers, can possibly pay. We only suggested, and that more by inference than direct statement, that planting tea is one thing, and selling it retail another, and that before it could be taken for granted that the two in combination offered a brilliant prospect of success, it would be useful to ask those who have tried it. In fact, we merely suggested further enquiry.

IT DOES NOT FOLLOW.—Because certain companies whose gardens are managed by experienced men on the spot pay handsome dividends, it does not follow as a matter of course that every retailer who carries on a large tea trade will do better if he grows the tea plant himself instead of buying the leaf in Mincing Lane. We did not, nor do we, now assert that any individual or company owning gardens in order to supply his or their shops direct must in all cases be in a less advantageous position, but in the absence of reliable details and figures proving the contrary, we certainly incline to the view that something of this sort is highly probable. Of course there is no more reason why a retailer of tea should not grow his own produce than that a tea planter should not sell his tea to his mother-in-law, but if in isolated cases of this kind success followed the experiments, it would hardly justify the extinction of the middle man, nor would it demonstrate that either the retailer or the planter could not have attained a greater measure of success had each stuck to his particular business.

NO REASON WHATEVER.—There is no reason why a retailer of produce should not grow that produce if he can nor do we know of any law of commerce, written or unwritten, which prevents a builder owning a timber forest, a tailor cloth mills, or a jeweller a gold mine. Possibly a shrewd man in either trades might find it useful and profitable to extend the sphere of his operations in this way. Says a clothier with a good connection and twenty shops all over the country, were he desirous to make his own cloth or even rear sheep for his wool, he could find managers who would carry out his views in Australia and in Yorkshire, and the idea might prove very remunerative; but it by no means follows as a matter of course that it would be so, or that he would make better clothes. There are

divisions and sub-divisions in trade circles, and we should deem a man prudent who waited to see the result of operations on the large scale before he essayed the venture on his own account. This is practically all we inferred, and we meant no reflection upon the correspondent or anyone else. So far from thinking the former had only superficial knowledge of the subject, we are prepared to credit him with considerably more than this, although we cannot go the length of believing with him that the working of a combination scheme for growing and selling tea, and then suppressing the grower, as such, as well as the broker and wholesale tea dealer, is the essence of wisdom. We strongly incline to the view that a clever buyer of tea in the Lane, who knows what he is about, can buy to greater advantage than he could if he invested his capital in and took the risk of tea gardens about which he knew next to nothing, although it does not follow that a clever and powerful combination of retailers might not be able to manage a tea plantation company in London with success. We notice that our correspondent is the "secretary of a tea plantation company now in course of formation," and we may trust he may test any theories he may have formed on the subject of growing tea and retailing it entirely to his own satisfaction.

CEYLON TEA AND PRODUCE COMPANIES IN ENGLAND.—Mr. Rutherford, the managing director of the Ceylon Tea Plantations Company, has compiled an interesting statement, which we publish in this week's issue, showing acreage, capital, and dividends paid for year 1890-91 of the Ceylon Tea Estate and other produce companies registered in England.

TEA FOR PERSIA.—Consul-General MacLean, of Meshed, reporting on the trade of Khorassan and Seistan for the year 1890-91 writes:—"The value of green tea imported during the year 1890-91 fell by £7,933, being only £17,781, as against £125,714 in 1889-90. But the value of black tea imported amounted, on the other hand, to £28,269, or £11,126 more than in 1889-90, when the total was £17,143. It may be noted here that all tea imported from Bombay by the Persian merchants of Yezd goes direct to Russian territory via Sabzawar. Of the green tea about £11,016 worth was Chinese tea purchased in Bombay, against £118,571 last year. The value of Indian green tea was £6,765 worth against £7,143 worth last year. Of Black tea £28,269 worth was imported, of which £19,706 worth was Indian, against £12,000 last year. Of the green tea about £98,365 worth passed on to Russian territory."

LAST WEEK'S SALES.—At public sale the supplies of Indian brought forward, says the *Produce Markets' Review*, have been smaller, and, as has been the case of late, the bulk has chiefly consisted of common qualities. Values generally show no alteration. The medium and finest kinds continue to meet with a fairly active demand, due, no doubt, to the unusually small proportion of teas giving a fine, strong infusion. As, most probably, the latter shipments will not bring a liberal supply of these grades, there is every prospect of their value advancing. The value of Ceylon teas shows little change, but there is still a tendency in the direction of higher prices for fine descriptions, and rather lower values for the common kinds. The best demand is for full flavoured brokens at from 1s per lb., but both leaf and broken teas worth about 8d upwards are in request at late rates. Below 7d however, a very low range of prices has been reached, and these grades undoubtedly show better value than has ever been previously known. It seems hardly possible that the trade can be fully alive to the excellence of the value obtainable at

from 6th to say 8th, or a much larger business than is at present passing would be inevitable. The quality of the bulk of the supplies on offer is still unsatisfactory, and no larger business can be done in medium and fine grades until there is a change for the better in this respect. The public sales comprised 15,137 packages, of which about 1,000 were withdrawn. The arrivals for the week are:—The "Breconshire," from Yokohama and Hong Kong; "Oonfaa" and "Polyphemus," from Shanghai, Foochow, Hong Kong and Colombo; "Clan Grant" and "Assaya" from Calcutta and Colombo; "City of Calcutta" from Calcutta; and the "Avoca" from Colombo.—*H. & C. Mail*, Jan. 29th.

HORREKELLY ESTATES COMPANY, LIMITED.

The annual ordinary general meeting of shareholders of the above Company was held at their registered office No. 22, Baillie Street, Fort, at about 1.30 this afternoon, there not being a sufficient number of members to form a quorum at the advertised time *v. z.*, 1 p.m. Mr. H. W. Bois (the Chairman of the Company) presided, and the others present were Messrs. C. E. H. Symons (Managing Director), E. Christian and Percy Bois (Directors), V. A. Julius, A. Schulze, W. Anderson, S. Green, and R. L. M. Brown (Secretary). Several shareholders were represented by proxies.

The notice convening the meeting was read and the minutes of the previous meeting having also been read, were confirmed.

The CHAIRMAN, in moving the adoption of the report and the accounts submitted therewith, said that, as they had been in the hands of the shareholders for some days past, they might be taken as read. He had little to add to the information contained therein, but he felt bound to state that the results for the year under review were disappointing in some measure, for, whereas the crop of nuts gathered during last year was larger than that of the previous year, the profit for the year amounted to R20,024 38 against R20,188 in 1890. The decrease in the profit notwithstanding a larger crop, was due to increased expenditure, chiefly under the item of manuring. The directors had carried out a system of manuring in the hope that corresponding benefits would accrue to the shareholders. The amount spent for manure last year was R4,547 against R2,166 in the year 1890 or an increase of R2,381. If this item were deducted from the expenditure side in the accounts, they would still fall short of their expectations. It might be perhaps suggested that, as the beneficial results will not be shown for many years, the cost should be carried to a suspense account instead of being brought in as a current expenditure; but the directors, after due consideration, had decided that each year should carry its new expenditure, as they found by experience that an opportune moment for bringing such expenditure into the accounts never arrived. There was an item of R1,000 outstanding for a period of two years, be understood, on account of the new clearing, which has now been brought to account, and at the present moment there was no item of deferred expenditure to be brought to account. It would be observed that a sum of R1958-82 had been written off for depreciation of Plant and Machinery in the accounts, which has been done in accordance with the custom of the last two years. The amount shown in the accounts as the value of property held by the Company was largely in excess of its actual value, and it was suggested that it would be a benefit to the Company if the capital were written down to the actual value of the estate. He did not wish to press the matter at the present time because he would be leaving the island shortly; but he would leave it to his successors to take the necessary steps in that direction, and he would recommend the suggestion as a course likely to tend to the benefit of shareholders. The pluckings of the nuts fell short owing

to unfavourable weather, and the crops which should have been gathered in November and December last have not yet been collected, and will accordingly come into this year's operation. He had nothing to add, and concluded by moving the adoption of the report and connected accounts.

Mr. A. SCHULZE seconded the motion, which on being put to the meeting was carried unanimously.

Rising immediately after, the CHAIRMAN called attention to the fact that, whereas in last year's account a balance of only R820-24 was brought forward from 1890, they were now carrying forward the much larger sum of R2,457-38 which, perhaps, might enable them to declare a better dividend for the current year.

Mr. W. ANDERSON proposed, and Mr. GREEN seconded, that a dividend at the rate of 5 per cent per annum payable on the 1st of April next be declared on the ordinary shares.—Carried.

The CHAIRMAN then stated that the next business was to elect two directors in the place of Messrs. H. Bois and E. Christian. It was necessary that they should be proposed by two shareholders not on the direction. As regards himself, he was about to leave the island, and it would be necessary to elect a director in his place.

Mr. V. A. JULIUS proposed and Mr. ANDERSON seconded that Mr. Christian be re-elected director.—Carried.

Proposed by Mr. PERCY BOIS and seconded by Mr. C. E. H. SYMONS that Mr. Julius be elected a director in place of Mr. Bois.

On the motion of Mr. SCHULZE, seconded by Mr. GREEN, Mr. S. T. RICHMOND was appointed auditor for 1892 on a fee of R100.

There being no other business to be transacted the meeting terminated about 2 p.m.

REPORT OF THE DIRECTORS.

1. The accounts now submitted for 1891 show that the profit on the year's working, after writing off R1,958-82 for depreciation of plant and machinery at the usual rate, amounts to R19,195 14, which, with the balance of R829-24 brought forward from 1890, makes a total of R20,024-38 available for distribution.

2. The Directors recommend that a dividend at the rate of five per cent be declared on the paid-up capital of the company, thereby absorbing R17,567—and leaving R2,457 38 as a balance to be carried forward to 1892.

3. It is satisfactory to note that the yield of copra is gradually increasing; and, as the result of observation and experience, the directors have resolved to carry out a systematic course of manuring the whole estate. The expenditure under this heading has in consequence been considerably increased, but every confidence is felt that results which should become apparent in 1893 will justify the outlay, provided the seasons are normal. The crop for 1892 promises to be a fair one, and will probably not show material difference in return from that of last year.

4. The working of the season 1889, 1890, and 1891 compared as follows (the item of interest being excluded):—

Expenditure on Estate and in Colombo			
Office ..	R33,448-77	29,492-09	33,576-28
Quantity of Coprah produced	805	941	995
Do. Coir Fibre made			
Ballots ..	43,358	21,850	41,804
Average price obtained for			
Coprah per candy	R39-36	39-94	41-08
Do. Coir Fibre, per owt.	4-54	6-16	3-65

5. Two Directors—Messrs. Henry Bois and E. Christian—retire and eligible for re-election.

6. The Shareholders have to appoint an Auditor for 1892.

By order of the Board of Directors,

R. LEWIS M. BROWN,

Colombo, 6th February, 1892.

Secretary.

MILDURA AND ITS SYSTEM OF
"INTENSIVE" IRRIGATION.

Respecting the great and promising experiments in process of trial on the banks of the River Murray, at Mildura in Victoria and Renmark in South Australia, we have deemed it our duty to supply our readers with a good deal of most interesting and suggestive information. A soil, good in its physical character and chemical constituents but in a climate where the average rainfall rarely exceeds eight inches, is first well cleared, ploughed and prepared for a foot and a half in depth, and then soaked with water raised by pumps of enormous power from lagoons in the river, such water containing in suspension doubtless much fertilizing matter. Fruit trees and vines are grown in the land thus treated*; and the grand difference between the "intensive" system of irrigation and that with which we are familiar, as applied to rice, is that at Mildura the effect of one thorough soaking of the soil lasts for many months, in some cases for the greater part of year. We have now received for publication a very graphic account by our correspondent "Aberdonensis" of a personal visit to and inspection of the Mildura settlement. Our correspondent's identity is well-known, and in this notice of the system of irrigation adopted at Mildura he specially alludes to the great but disappointing experiment made by his father, the late Mr. Robert Boyd Tytler, to irrigate coffee in Dumbara valley. We well recollect Mr. Tytler's telling us that to him and his partner the difference between a wet year and a year of drought was that of £10,000 in their receipts. As years of drought were the rule in the valley, an expenditure of £20,000, on a canal, turbines and pumping machinery which by raising the water of the Mahaweliganga to the highest point of the estates, whence it would be distributed over the coffee, so as it was hoped, securing the advantages of a wet year, seemed prudent and justifiable. But difficulties which had not been calculated on marred the success of this really grand scheme, of which, at the time, we gave a full account in the *Observer*, embodying the details in the account of the Dumbara Valley contained in the Handbook for 1859, the first of the series. Our correspondent, after seeing the Mildura system of water allowed to soak into soil loosened and comminuted to a depth of eighteen inches, recognized at once the fatal defects of the Dumbara scheme. The soil was not, and being already planted could not be, properly prepared to receive water from channels which were equally impossible from the nature of the ground. At the height to which the Mahaweliganga water was raised, the pressure was such that it burst in devastating jets from the pipes, cutting up and carrying away the soil it was intended gently and steadily to irrigate. The Dumbara experiment was therefore (alas!) as much a failure as that at Mildura is likely to be an assured success. The only doubt now felt is the same as that which besets tea growers in Ceylon, lest the success should be too great, ending in over-production. But, happily, fruit, like tea and even more than tea, is a necessary of life, an article of daily food to a large portion of mankind, while multitudes are waiting to become consumers when the pleasant and wholesome and nutritious fruits are placed within their reach. Even more in a preserved, canned and cooked state are fruits acceptable as food constituents; and the tendency of the day is

towards a diet consisting less of meat and more of fruits and vegetables, than is at present the rule, especially in countries like Australia, where beef and mutton are so plentiful and cheap. Our correspondent's visit to Mildura took place on a day exceptionally unfavorable in meteorological conditions; but while he honestly states the impressions he received under such conditions, his verdict agrees with the favourable opinions delivered by all unprejudiced visitors to the Irrigation Colonies founded in Australia by Messrs. Chaffey Brothers, with the advantage of all the experience previously obtained in connection with similar settlements conducted on similar principles in California, where "Riverside" is a monument of well-directed enterprise, science, skill and industry. The best proof our correspondent can give of the sincerity of his favourable opinion of Mildura is his earnest desire that he had the means to purchase a block and become one of the settlers. We sincerely regret that his father's son should not be in a position to gratify so modest a wish. But we trust better success may reward his real ability than was the case in Ceylon. Meantime the lively and interesting account of Mildura will interest all our readers and may be of special use to some.

THE RICE TRADE FOR 1891.

Messrs. Fraser and Co.'s annual review states:—The trade for the past twelve months does not afford very much scope for an interesting review. Indeed, for the first seven months of the year, nothing of importance arose to cloud the horizon, and there was a minimum fluctuation in prices, thereby allowing purchases and sales to proceed on the even tenor of their way without any extraneous excitement. There appeared to be the prospect of rice enough and to spare, notwithstanding that the expected surplus available for shipment of 400,000 tons from Japan turned out to be over 300,000 tons short, and the "good prospects" enabled from Saigon resulted only in 33,565 tons! A larger quantity from Burmah, however, had to be reckoned with, and an extra amount from Bengal, while even Persia sent a few thousand bags more than in the previous year to swell the list. Still the rice trade had its little flutter, as most trades have just to relieve the monotony of registering what had almost come to be considered as standard quotations. According to the published statistics from certain European ports, it was evident that consumption had wonderfully increased in several districts, and with the end of July came a breath of suspicion that this increased demand might exceed the probable supply, and before summer was over prices were 1s. per cwt. dearer! The Aogast boom was not so short-lived, as such sudden advances generally are; millers had rushed in where even speculators feared to tread, and, consequently, a level of rates above 8s. for Rangoon rice was maintained to the end of the year. Once more steamer shipments have increased in comparison with the quantity taken by sailing ships. 100,000 tons over last year is a large increase, the actual figures being 677,700 tons against 566,800 in 1890, 466,480 tons in 1889, and 378,390 tons in 1888. Frights fluctuated between 32s 6d and 40s during the year, and similar rates have been paid for the coming season. Cleaned Rice: Speaking generally, we think we may describe the trade of the past year as very satisfactory, both to millers and dealers, and it must be noticed that so far as London and Liverpool are concerned, millers are fast adopting the position of dealers, there being, in face of continued and increasing shipments from Burmah, but few opportunities left to them to mill rough rice to advantage. They therefore meet their altered circumstances by purchasing the cleaned instead of the rough article, as formerly, from Burmah in large

* With the exception of apples, which grow well in the colder parts of Australia, and especially in Tasmania.

quantities, and, so to speak, become distributors and retailers to provide the requirements of their buyers. Although the shipments to Europe and America have increased to the extent of some 50,000 tons, the shipments to the Far East, Straits, China, and Japan, have fallen off to the extent of about double this quantity, which is almost entirely due to the absence of demand from Japan, which drew so largely on Burmah in the previous year, in consequence of the partial failure of the crop in that country. The course of prices has been generally a steady rise throughout the year, embracing an advance of about 1s 3d per cwt on shipping quantities of Rangoon, while cleaned broken rice and rice meal showed at one time an improvement of 2s to 2s 3d per cwt from the lowest point. Values ranged as follows: say, fair shipping qualities of Rangoon, Bassain, and Necessie, 8s 7¹/₂d to 10s, Patna 10s to 13s 9d, Japan 12s 9d to 14s. Japan: Contrary to general expectations, shipments were on a much smaller scale than foretold in our last review. Although the crop of 1890-91 was undoubtedly very abundant, the troubles consequent on the failure of the previous crop seem to have created a feeling of anxiety throughout the country which had the effect of maintaining values at such a high level that exports were necessarily curtailed. We had the highest authority for stating in our last year's review that quantity available for export would be some 400,000 tons, but as a matter of fact, the actual shipments did not amount to more than about 25 per cent of that quantity, and were distributed as under:—Shipments to Europe, 80,000 tons; America, 14,000 tons; Australia, 4,000 tons. The quality and condition were extremely satisfactory as a whole, and the deliveries of the rough grain were without exception, quite up to the selling standards. Some of the cleaned shipments were, on the other hand, most disastrous, and in some cases as much as 3s to 3s 6d per cwt. was awarded to buyers for difference in sample. It is only fair to state, however, that these great differences were due to damage by either sea or fresh water and also to the presence of worms which infested some parcels. We attribute these troubles to the fact of the damage having taken place previous to shipment, most probably from being kept a long time in stock in Japan, and not from any fault in the actual cleaning. Prices ranged from 10s 3d to 11s 9d for rough and the cleaned, which was chiefly sold on a fine standard, at about 14s per cwt. For the coming season only about 8,000 tons have been sold at from 11s to 11s 9d delivered terms. The crop is said to be a fair average one, but the recent disastrous earthquake has so unsettled the country, that it is extremely difficult to say what may be the result. All that is known is that prices remain very high, and the speculative element is quite master of the situation. In a country where this feeling is so rife, it is quite possible the present range of values may be maintained, as last year, in spite of ample supplies, though the typhoon in the month of September is said to have reduced the available quantity of export quality very considerably; at the same time the Northern rice, which is not suitable for export, and is entirely consumed in the country, is said to be very abundant. Java: Shipments continue on a comparatively large scale, and exceeded those of the previous year by about 3,000 tons. The quality was fairly good, though some parcels shipped to London were found to be considerably under the standard of sale, being chiefly deficient in colour and containing too great a percentage of broken. As usual, the bulk of the imports were landed in Holland and prices are difficult to trace. The values of shipments to London ranged from about 11s to 14s 3d per cwt. Siam and Saigon (Oochin China); Shipments of both descriptions were less than the previous year, especially from Siam, where the crop suffered very considerably from drought, and the quantity shipped to Europe was some 70,000 tons less than in 1890. Saigon, on the other hand, contributed within about 4,000 tons of the total of the previous year. The qualities were fairly good, and the Saigon shipments were nearly all taken by France, where the protective

system favours this grain to a very marked degree, coming, as it does, from a French possession. The rates obtained for cargoes ranged from about 7s c.i.f. for Siam, to 7s 1¹/₂d to 7s 2¹/₂d for Saigon.

The total shipments of Siam to Europe were 9,950, against 80,500 tons in 1890, and 59,000 tons in 1889, and 110,000 tons in 1888, and from Saigon 33,565, against 37,000 in 1890, 17,400 in 1889, and 71,500 tons in 1888.

New crop prospects in Siam are less promising than last year at this time, when a partial failure was predicted. The reports so far seem to point to there being no available supplies for Europe, but on the contrary it would appear the crop has suffered to such an extent, that there may not be sufficient for the internal requirements of the country. The crop reports from Saigon are good, and already over 40,000 tons steam-milled, including some 4,000 tons pneumatic shelled, have been sold for shipment to Europe during February, March, April and May, at about 7s 4¹/₂d and 7s 3d c.i.f., shipping weights.

CHICKENS IN HOT WEATHER.—Attention has been recently called in the Poultry Yard to the fact that chickens suffer very much exposed to the sun when the weather is hottest. They will pant and manifest their feeling of discomfort as plainly as will the oxen when tugging at the plow. They will gladly avail themselves of the shade of a tree or wallow in the cool earth in the shadow of some building, stretching out their wings and legs to cool themselves. In the summer months, if they are confined to a bare yard, with no trees, no buildings large enough to make a protecting shade, nothing but the bare coops, it may be seen that these get heated through, being so small, and afford inadequate protection. Chickens thus exposed are certainly in a pitiable condition. They cannot thrive because uncomfortable, and when night comes it hardly brings relief if they have to huddle in coops that are ill ventilated. The chicks should always have access to a good shade in the hottest weather. —Florida Agriculturist.

"THE FUEL SUPPLY OF THE FUTURE: A NOVEL SCHEME."—Such is the taking title of an account in the local "Times" of the alleged discovery of an "interesting visitor," a Mr. Edelmann, who has been everywhere and seen everything and who has discovered a process of distancing nature some thousands of years by converting poor lignite into true coal! It is vaguely hinted that chemicals are to be added to the lignite, before pressure into dense and hard "brickets," which are to be the fuel of the future. "Just what we want for our tea factory furnaces," will occur to many a planter; but unfortunately though we are told that Mr. Edelmann thought of Texas, but decided in favour of France for the scene of his factory (unpatriotic decision for a man with a German name.) Not a word is said of the cost of the chemicals or the price at which the fuel of the future is to be turned out in France or at which it can be laid down in Ceylon. We know nothing of Mr. Edelmann; but we confess that the narrative of his alleged discovery impresses us more with sceptical doubts than with sanguine hopes of poor lignite being converted into first-rate coal as "the fuel of the future." We should attach much more importance to an alleged discovery that the fuel of the future is to be derived from water-power converted into electricity.

MILDURA: VICTORIA, AUSTRALIA.
THE NEW IRRIGATION COLONY.

I have just visited the new fruit-growing colony of Mildura on the Murray River, and now sit down to give your readers as good an idea of the place and its prospects as is possible in a letter of this sort.

THE START BY MESSRS CHAFFEY.

Active operations were commenced by Messrs Chaffey (pronounced long a as in chafe, not as in chaff) on the 1st October 1887. To give your readers a true idea of what sort of place it was, and the unpromising nature of the climate, I will quote from a letter by "Jethro Tull" which appeared in the *Queenslander*:—

"Looking at the Lower Murray district with the eyes of a Queensland pastoralist, I class it as the most wretchedly inferior of all grazing country. I knew it intimately when it was in its prime, and I see it now that it has been grazed over for 50 years; 80 acres would not keep a sheep! Mildura Station was one of the largest squatting runs in the district, yet it supported probably not more than a dozen souls the year round. It originally belonged to Messrs Phelps and Jamieson, who sold it some twenty-five years ago, just when experience was demonstrating, that even in wild dog and scrubby country sheep could be kept at large instead of being shepherded. It was then fenced in and 80,000 sheep kept on it for years, then again the owner wisely sold. The new purchaser expected to do the same as his predecessor, and keep permanently 80,000 sheep; but the cream had been skimmed by overstocking and the rabbits had come. It fell into the hands of a banking institution, and remained on their hands unwittingly. Mr. William Paterson was the manager. One day about four years ago, at a neighbouring township, a quiet middle-aged gentleman came up to Mr. Paterson and without giving his name, stated that he was on his way to Mildura and would like to stay a few days. He was mistaken by the manager for a drummer of an Adelaide firm who had sent up a case of execrable whisky, so he was told 'he might save himself the trouble, for he was not wanted.' Half an hour afterwards the stranger quietly came up again, said his name was Chaffey—George Chaffey—and handed a letter from the manager of the bank, which simply intimated that the bearer was a 'probable buyer of the Station.' The station manager felt awkward, decidedly awkward, but apologised and explained, and the 'probable buyer' laughingly admitted that a case of *bad* whisky was amply deserving of a rough reception. At sundown the pretty homestead was reached, and the evening spent over *good* whisky,* by the manager talking 'sheep' and decanting upon the inferior grazing capabilities of the run, and the probable buyer quietly listening. It transpired during the evening that the new comer was a new ehnm to the colony, was new to squatting, and had the money. 'What a godsend' thought the manager; 'it shall not be my fault if I don't shove the old worn-out run on to him. Next day the horses were got up, and the inspection which could not possibly be done under several days, commenced. The manager took the lead, and did the talking; the lead was over the salt-bush plains and through the straggling open mallee, and the new ehnm was told of the exceeding fattening quality of all salt-bushes, and how open mallee was equally as good as the plains; ho

was told that the absence of grass was nothing, for that after the slightest rain numerous saline herbs grew, all eagerly relished by sheep. The belts of dense mallee and pine ridges, where not a blade of grass was to be found, were carefully avoided, and the ride home was along the river-flats, where, under the huge red gums and the stunted box, flooded grass was long and plentiful; and the manager thought he had made an impression. Next day the new ehnm began to assert himself; he had kept to the river, inquired as to how low it fell in the summer, how long it kept in flood; examined the cliffs and looked at the subsoil, and at the subsoil exposed in any rain-gullies; was greatly pleased with the long anabranch or 'billabong,' how deep was it? how was it filled? did it retain the water? &c. &c. The dense mallee belts avoided the previous day were not only visited but critically examined as to soil and sub-soil—so were the pine-covered sand hills. Would he 'not go and see the sheep?' suggested the station manager. "No, I suppose they are what you say they are; but how high do you suppose the ridge is above the river? that distant pine scrub must be higher. Let us go and see it," was the strange reply of the stranger. The pretty garden, too, at the home station came in for careful examination, every tree and shrub noted, and particular pleasure expressed at the oranges and lemons, and the vines. Conversation slackened somewhat that evening. The manager was completely non-plussed; he had had his say, and had got a rank new ehnm to say it to, but what was the good when his man did not care whether the points of the station were good or bad. He was asked whether there was a theodolite on the station. 'Yes, we use it to run boundary lines. You will find them quite correct.' 'I should like to take it with us tomorrow' was the quiet reply of the green new ehnm. The manager said nothing, but thought a good deal as he went to his room to bed. Next day the theodolite was taken, but not to the boundary line. Oh no! only to the river bank, and the height above water noted. Then the height of the salt-bush flats and rises, and their heights marked down in a pocket-book; then this, that, and the other mallee and pine ridges had their levels taken, till at noon a halt was made for lunch and the whisky brought out. The station manager felt himself worked up to a 'ropeable' condition. He could stand this tomfoolery sort of inspection no longer. This man is no squatter but a—fool, and what is the use of wasting time over him? So out it came. 'Look here, Mr. Chaffey, you are a mystery to me. Who are you? What do you want? Are you a bona-fide buyer? You seem to care nothing about the quality of the salt-bushes or herbs, never even look at the grass, and will not go to see the sheep, but instead keep poking about the river and taking the levels of these barren mallee ridges. What is your game? I have been trying to pump you these three days. I am sick of this useless work.' Then the quiet new ehnm smiled, and quietly replied, 'Mr. Paterson, you are not the only one who has considered me a mystery during this visit down the Murray and my inspection of several stations; all have tried to pump me and ineffectually, but I will tell you. I like the place and shall buy it.' 'Why, you haven't even seen the sheep.' 'No, but they do not matter.' 'Good heavens!' exclaimed the manager aloud, and to himself he thought. 'What a greenhorn!' Then the quiet man slowly unfolded the gigantic schemes that were working in his brain. Told of the irrigation colonies he had successfully organized in California. How he had come to Australia to

* The Messrs Chaffey are, we believe, abstainers.
—Ed. T. A.

duplicate these on a still larger scale, and how he contemplated irrigating 250,000 acres of the Mildura run! The station manager was as one thunder-struck. 'Greenhorn indeed,' he thought, why I am the greenhorn."

This visit of Mr. Chaffey was the result of the visit of the President of the Victorian Royal Commission to California when Messrs Chaffey Brothers were invited to Victoria. The first thing done was the passing of an act whereby 250,000 acres of land were set apart for this enterprise. "The license to occupy the area named for a term of years was first granted, with right of acquiring a free grant of the land set apart by compliance with certain conditions as to expenditure upon the land. The minimum expenditure stipulated for by the Government was £35,000—within the first five years. As evidence of the energy and good faith of the Messrs Chaffey, it may be stated that the total expenditure to the 30th June last, certified by the Government auditors, amounted to no less than £183,835; the company has therefore expended in three years more than five times the amount required to be laid out during five years."

THE JOURNEY TO THE MURRAY.

By the courtesy of Mr. Levein, the chairman of Directors, and the Secretary, I obtained a free pass by the river steamer, so I had only to pay the railway fare. I could have procured a pass by rail if it had not been holiday time. I started from the Melbourne Cricket Club ground where the great International Match was going on and caught the 5-10 p.m. train for Swan Hill on the 2nd January 1892. As we left Melbourne the country opened out into wide fields, or as they are called here "paddocks," on which sheep and cattle are grazed. The country before dark became of a more wooded character, and hills covered with small timber arose on both sides. We had to change at Bendigo—or as it was called for a time Sandhurst—a great mining centre, but the darkness prevented me from seeing anything outside the train as we passed along. The latter part of the journey towards Swan Hill was like a hideous nightmare. The train was undoubtedly late but that did not justify the driver in making up for lost time and in jolting and shaking us—not only out of sleep but almost out of our minds. A shattered, weary being, I stepped out of the train at Swan Hill at about 2 in the morning along with a number of young fellows evidently for Mildura like myself. "Cab, sir?" "Where 's the steamer." "Down at the Wharf. Very dark sir." "What do you charge?" "Two hob." "I have only one shilling change." "All right, we'll manage it." I found the "steamer" lay about two or three hundred yards away; and I heard subsequently that this youth who drives the "Royal Hotel" cab fleeces strangers by charging them 2 shillings for 300 yards! We drew up to a large building with a bright electric light at one end, and this I discovered to be the steamer "Pearl." It looked more like a "building," than a boat. It had two decks above the main one, it drew only a foot and a half of water, and it carried its water-wheel behind it. It was the first boat of the American type I had seen. I went upstairs, into the saloons, and there I found supper in the shape of a substantial meal waiting for us. This we presently partook of, and then came the delicious calm and peace and softness of bed after the rnde hard jolting and swaying, after the roar and the rush, after the clatter and crash.

DOWN THE MURRAY.

Next morning the first sensation was a gentle throbbing of the boat, the next the sight through a corner of the outward door of wooded banks

gliding past, and the next numerous calls of birds. I dressed and went on the top deck and enjoyed to the full the view. The tortuous Murray, winding through and through the gums, with hers a lagoon or billalong with its glassy surface dotted with innumerable water-fowl, there a grassy plain and large fields of rushes and reeds. Ducks and teal whirled round us, "shags," divers, and cormorants lazily flapped along the river in front of the steamer, and graceful black swans would sit proudly on the water in some bend of the river as we passed. What a place for a double-barrel and a retriever. The tanks in Mysors, or the "wewas" in Ceylon could not approach this. Simply thousands of duck and teal, and good fishing on the river. We saw a ruda tent and an uncouth being engaged in fishing. Strange existence. Now and again a "station" would be seen on the high banks, and now and again woodcutters' huts were visited as the steamer lay alongside the banks while the crew leisurely handed in firewood. And so from morning to evening. A calm restful gliding along, with a solemn procession of sombre gums moving past in monotonous numbers. Once we saw a flock of smus daintily picking their way through the wooded flat, and another time we disturbed a number of kangaroos who leaped away in a crippled sort of fashion, but "nary a cripple" in the pace they went. They tackled a hill at the cliffs in a way that showed they were built for speed, but they are very much out of drawing for all that. Then the omnipresent, much persecuted, the universally execrated, the cursed and hated rabbit—poor "Buany"—your chief fault is your multiplying powers. Drinking at the river, or scudding along with their white tails bobbing up and down through the trees and tussocks—the rabbits in some places were very numerous. Many black rabbits were to be seen, but the prevailing colour was the ordinary gray. Good sport could be had by bringing a rook-rifle and lots of cartridges and potting the rabbits from the boat. Sometimes passengers would only wound and maim beautiful water-fowl and leave them fluttering in anguish and their fins plmags dragged in blood and water. As there is no chance of getting the game surely such "sport" should be strongly condemned. But it is different with rabbits. They are classed with rats here, and a rook-rifle would be useful.

One evening we stopped for a long time at a large station—I think it was the "Mallee Cliffs" Station—to take in a cargo of wool. The wool-bales were lying on the bank I stepped ashore on New South Wales land for the first time. With another passenger I inspected the wool-shed and sheep-pens, and the wool-press &c.;—then we saw the men's sleeping places and dining room—very rough I thought;—then the other houses and carriage shed and beyond, the house, itself with its windmill and luxuriant orchard. Straight off stretched a brown dusty plain along which a cart, occupied by two men and drawn by a horse with a spare horse following after, was slowly moving homeward—its progress marked by a long cloud of dust. Near the house we encountered a fearful smell, and found it came from a dead rabbit that had paid with its life the penalty of its rashness in venturing within sight of the kangaroo dogs to nibble some of the greenness in the garden oasis. These dogs were very friendly. At last we started away down the river and in the night we arrived at Mildura.

MILDURA.

I was not greatly taken with my first view of Mildura. I saw a dry dusty river-bank littered with cases, barrels, planks, and sacks in an untidy fashion, like the fragments of a wrecked civilization on the hard dusty shore of the desert. Right

opposite is an iron vessel being built, and another steamer "The Nellie" is being fitted with deck cabins. No sign of the vineyards, none of the "intense cultivation," none of the wilderness blossoming with the rose. A good deal of "wilderness" and precious little "rose." To make matters worse the day was exceptionally disagreeable. A hot, dry, close, dusty, beastly, ghastly day. I was not in a good humour. I tackled some settlers in the coffee palace verandah and jeered at the place and was taken up rather sharp in consequence. "I don't think much of this place," I said. "Why not?" asked the settler. "It's a dry, hot, dusty place and hardly up to the glowing accounts I have read of it." "I think you are rather hasty," said the settler. "In the first place you haven't seen it yet, and in the second place it is an exceptionally beastly day; but you will change your mind before you go." Well, two drags came dashing up, each driven by four horses. I was in no hurry to see Mr. W. B. Chaffey, to whom I had letters. I wanted to see for myself; so I climbed on to the drag. These drags await the arrival of steamers and take round visitors. The fine horses, bay leaders and grays at the pole, rattled us in fine style through the infant city and away along the track. The township was scattered over with houses large and small, tents of sorts, and all the debris washing on the advance tide of civilization. Here a really fine shop, there a squalid makeshift with most of the household goods strewn around and the inhabitants in "dishbills." Then a fine school, then a tiny cottage of weather-board and iron roof. Then a little box entirely made of iron which was more fitted for an oven than a dwelling-house. By the way, they have what is called "refrigerating" paint, which when applied to corrugated iron remains cool to the touch after being exposed to a fierce blistering sun. This renders iron dwellings endurable. It might be a "tip" worth knowing by some of your planters for their bungalows and factories.

We stopped first at Mr. Isard's place. We climbed down and walked along the short avenue. He has 10 acres and is making his fortune. He had struggled hard for years on the bleak Tragool Plains in trying to grow crops with irrigation—but three years ago he came here, and here he means to stay. I separated myself from the others and made for a young man who was irrigating. "How often do you water like this?" "Well, these apricots haven't been watered since last February and the grapes a year last month." "Good gracious! do you mean to say that is all you require?" "Well, we can't give the trees more than is necessary to crop and grow fresh wood; and a good soak about once a year goes a long way." "You don't flood the land?" "Oh no, a quiet thorough soak. You can soon tell if the plants get too much water." "Can you get water when you want it and as much as you want?" "Well, we may not get it on the very day we ask for it—but then it's sure, and a day or two doesn't much matter." "How about the work? How do you get the labour to pick the crop and do the work?" "Well, I took in all the crop last year. Mr. Isard doesn't do very much in that way. Of course I had to put in some long days." The apricot crop had been gathered, and the grape crop was still green, but everything was green and luxuriant. I took up some of the soil and squeezed it in my hand. It was a soft sandy light chocolate loam—in perfect mechanical condition—and evidently full of manurial properties. The water, supplied at the highest point of each allotment, is not allowed to splash or inundate the soil, but is led along furrows formed by the plough on each side of the young plants planted about 12 to 15 feet apart. Seeing signs of pruning on the apricot trees, I

asked "Why did you prune back those branches?" "Only for the wind, sir, they get too straggly." I found they had picked about a ton an acre off 5 acres of apricot. The other five acres was made up of a small vineyard and the cottage and surroundings. I noticed a snug arbour—embowered with creepers and looking out on the orchard. Only 10 acres and making his fortune chiefly by the local demand for fruit at good rates. That's hopeful any way. I climbed into the drag and away down the broad avenue;—past fields being brought into order by Chaffey's gangs, past a cardhouse and a few fowls and a woman weeding the young vines planted last season; over, now and again with a dash, the bridged water channels along which the precious fluid majestically moved far up on the ridges along the highest features of the land. Past ploughmen, past irrigators whose work was evidenced by the glistening furrows and darkened soil. Then into the mallee scrub and along the fine ridges where speculators held but left untouched large blocks. Out again into cultivated spaces, makeshift residences, and at last we arrive at the Billabong Pumping Station. Now I must stop a minute or two and describe the Pumping Apparatus. And I would mention that all this stirred my heart strangely when I thought of my father's struggles to carry out the same splendid thought. The pluck was there, and the money was there. The water was there and the fine rich soil and dry climate were also there. But alas!—40 years ago—knowledge and skill such as is possessed by such experts as Messrs. Chaffey were sadly wanting, and nothing remains in dry Dumbara but a splendid ruin of machinery, and washed and wasted hill-sides; where the abundance of the water carried up heights undreamed of by any other cultivator in the world acted as a destroying instead of a beneficent power; where the constant surface weeding and surface splashing and too frequent wottings gradually resulted in a huge failure. Ah! if they had but known. If they had only realized that a soaking along graded and pulverized ground once in 6 to 8 months was sufficient. Then the height to which the water was carried, some 200 feet over the Ambacotta Gap.

Before I go on with this description I must find vent for the rushing thoughts that crowd my brain. Chaffey Bros. have found the key to many "Eliseums of Bliss," many enchanted gardens besides those in California and on the banks of the noble Murray. Thoughts of your noble tanks and irrigation by rain-water storage and gravitation. Surely some of all this knowledge here exemplified would be of use not only in your dry districts towards the north in growing cotton, coconuts, and cacao under irrigation, but also over Indian's arid and barren wastes, where, as here, noble rivers flow through desert-rainless wastes. But irrigation is a great fact there. As I stood on the famous rock of Trichinopoly, the richness of country over which the Cauvery had been spread into countless channels proved the value of water.

The water-right, by an agreement dated 30th November 1887, has been transferred from Messrs. Geo. and W. B. Chaffey to Chaffey Bros., Limited, together with all other rights, privileges, licences, and authorities obtained from the Government under the agreement, previously mentioned. The next stage is the control of the water right, which in reality is of far more value than the land. In California, no matter what capital is set upon unimproved land, the moment it can be shown that water can be made available for irrigation its value is calculated to have increased fivefold even before cultivation and planting commences

As every purchaser of land, therefore, at Mildura obtains an interest in this water-right, proportionate to the area of land he holds, it is interesting to narrate the method by which rights and interest are secured. For the purpose of apportioning the water right, and conveying it to purchasers of Mildura Lands, an organization called the Mildura Irrigation Company has been formed. Under agreement dated 25th January 1889, the firm of Chaffey Bros. Limited, vested the water-right in this company, and handed over to it the management, control, and supervision of all waterworks in connection with the Mildura scheme. All pumping machinery and appliances, dams, channels, reservoirs, sluices, and pipes, and other means of raising and conserving water, and for carrying a sufficient supply for irrigation purposes to the highest point of each block of 10 acres, are provided by the firm of Chaffey Bros., Limited, and handed over in working order, *free of cost*, to the Irrigation Company. This means that the works are handed over to the people who own the land, each owner securing an interest in such works in proportion to his acreage. This will be explained by a few words as to the constitution of the Mildura Irrigation Company. There are 250,000 shares in this company corresponding to the number of acres comprehended in the scheme. Every acre represents one share in the Mildura Irrigation Company, and the acre and the share go together. When anyone buys land from Chaffey Brothers, Limited, he receives a paid-up share in the Mildura Irrigation Company for each and every acre transferred to him. He must sign an agreement, which is attached to the title, that he will transfer none of such land unless to persons willing to also take shares in the Mildura Irrigation Company. These shares must go with the land, however conveyed, whether by sale, deed of gift, mortgage, assignment, or execution under process of law. Every precaution that legal knowledge and ingenuity can devise is taken to incorporate the water-right which is represented by these shares with the transfer of the land. Any failure or neglect on the part of the proprietary firm in this respect would be regarded as a distinct violation of the agreement with the Government. When all the land is sold the entire water-right will have been conveyed with it to the various purchasers. As each system of works is completed and set in going order, it is handed over by Chaffey Brothers, Limited, and the after-expense of maintenance and working are borne by the Mildura Irrigation Company. The affairs of this Company are managed by a Board of Directors elected by the shareholders (landowners), who will levy an annual charge on each owner of land for the purpose of raising the funds necessary for maintenance and working expenses. Up to the present time water has been supplied to the settlers free and the annual rate has not yet been fixed. It is expected however that it will not exceed 6 shillings an acre. Now for the pumps. The first pumping station lies 14 miles up the river "Psyche Bend" where the great "billabong" or lagoon leaves the Murray. This station is only 7 miles by road and two traction engines are busy throwing 4 streams of water into the billabong. Here the Company are erecting an engine of 1,000 horse power indicated, and enormous pumps of 40 (forty) inches so arranged that either or all can be used as required. Each pump (centrifugal) is capable of pumping 30,000 (thirty thousand) gallons per minute, so that the whole pumping capacity will be equal to 120,000 (one hundred and twenty thousand)

gallons per minute. Here is a monster pump! The lift will be from 20 feet to nothing according to the level of the water in the river. The bulk of the water will not be taken from the Murray but from this huge billabong which has an average width of 150 yards and an average depth when full of about 30 feet. The water in this lagoon rises and falls with the Murray, but both ends have been locked so that the water can be stored. Well at Psyche Bend we have an engine of 1,000 horse-power and pumps equal to 120,000 gallons a minute and at the other end of the billabong we have the other pumping station which has an engine also of 1,000 horse power and 4 pumps in full working order capable of lifting altogether 40,000 gallons per minute. They can be worked together or separately and the water can be discharged into either the 30 feet, or the 50 feet channel. There are five of these channels,—the 30 feet, 30 feet No. 2, 50 feet, 70 feet, and 85 feet respectively. At Nicholl's Point, on the 50 feet channel, there is a third pumping station to raise the water from the 50 feet channel into the 70 feet and 85 feet channels. These pumps and the engine are of the same strength and capacity as the one just above mentioned at the billabong. Then there is the pumping station at the town of Mildura from the Murray, where a 200 horse-power engine lifts 1,500 gallons a minute 78 feet high to supply the township. There will be erected a large water-tower from which water will be laid to every dwelling, and which will give pressure in case of fires. The fifth pumping station is at the old Mildura homestead with a 200 horse-power engine driving pumps equal to 10,000 gallons a minute into 30 feet channel No. 2. The total pumping capacity of all these stations is equal to 200,000 gallons per minute, but as the big "Psyche Bend" pumps will only be used as a standby in the event of a very dry season to pump from the Murray into the billabong, only 80,000 gallons a minute will be available for irrigation purposes. Roughly speaking 25,000 gallons is equal to an inch of rain per acre. 80,000 a minute is equal 4,800,000 gallons per hour, or 115,200,000 per day of 24 hours. 80,000 gallons per hour will furnish in inch of water to 4,500 acres per day of 24 hours.

The main channels, or canals, are 25 feet bottom width, and 4 feet deep. Over 60 miles of main channels were constructed in May last and I suppose about 30 miles more are in course of construction. The main channels cost about £500 per mile, and are kept carefully clear of weeds and growth. The Psyche Bend pumping station will cost £15,000 and the total cost of pumps, engines, and channels will cost nearly £100,000.

During the year 1891 the outlay on permanent works exceeded £9,000, making a total of £330,000 since the settlement was formed. 3,000 acres have been planted this season at £8/10 per acre equal to £25,500. About £250,000, including living and general outlay by settlers, has been spent in 1891.

The Cottage Hospital, Main Hall or Public Institute, and Mr. O. B. Chaffey's new villa will total £8,000. There are about 3,600 of a population. There have been 25 deaths in the year. Mr. Speight of the railway prophesies that Mildura will be the 4th city of Australia.

Now on the banks of the billabong we have been figuring all this out, we have looked at the big engine and pumps called "The Chaffey" after the designer Mr. Geo. Chaffey, and then we have climbed into the drag again better fitted to

understand matters. Presently the driver gets out, handing the reins to a passenger, and pronounces one of the axles heated. "I'll drive up to that house and see if we can get some butter or something." We not only found a tin of grease, but a movable spanner all complete, so the wheel was taken off and greased. "He's just forgotten that wheel. I didn't expect to find everything we wanted at the first house." The hot dusty wind was intolerable as we drove along across the flat where the most of the more forward hocks lie. Let me quote "Telemachus" in the *Argus* of 13th December 1890:—"We enter immediately on a series of orchards, and vineyards and gardens. There is the lemon patch of the Rev. R. J. Houson Smith of Wentworth. Then among its trees and flowers, Mr. Appclby's neat adobe house. Next, well tilled and luxurious, the 25 acre vineyard of the late Mr. Eric Farquharson. A sad association this. There are some among us who followed that gallant young rider to his grave not long ago. There are many who knew him as a bright and genial companion and enterprising colonist, and who hoped to have him as a neighbour through all the colony's development. Further along is Messrs. Troine and Beecher's plantation of apricots, oranges and vines, 22 acres in all—and beyond a neat gate and fence the newly established home of Mr. F. G. Hodge."

Mr. Hodge's villa and surroundings are as nearly perfect as one can get in this world of disappointments and sorrows. He has 5 acres apricots 30 months from planting and picked 3,000 lb. He has 3 acres prunes, 4 acres oranges, 8½ acres Godo Blanco vines; and the rest of the space is taken up by the buildings, the grounds and ornamental lawn and trees; while there is a paddock of nearly 6 acres for lucerne and wheat for horses, &c. Opposite is the land chosen by Mr. Levien for his boys. Mr. Hodge works his own land with the help of one man and one horse. Constant employment, good returns, fine house, grand climate, plentiful water—a paradise indeed!

I called at "the office" which is externally a show place. It is surrounded by flowers and a beautiful lawn of buffalo grass with a fountain playing. I was shown into Mr. W. B. Chaffey's room and was courteously received. He apologized for having been so busy, and I remarked that I had been for a drive round in the drag in the morning. "It is a pity I did not see you sooner. I could have sent you round more carefully and had things pointed out and explained." I answered that as a planter I would like to see certain special things than he shown too many gardens and taken long distances. "Will you come and see the apricot drying?" I gladly assented, and stepping into the covered buggy I sat beside Mr. Chaffey while "Fred" his crack driver sent the fine brown horses along smartly. He pointed out his new fine villa which he modestly termed his "new crib," and said he meant to make a good thing of it before he was done. We drove up to a gate where in a field of green lucerne a group of men were engaged in drying and curing apricots. We went towards them, Mr. Chaffey remarking that they dried in the lucerne so as to avoid dust. The tramping only threw it back a short time. The dried fruit was simply beautiful. It is first fumigated in sulphur fumes which seem to fix the syrup, and also preserves the colour of the fruit which could otherwise blacken while drying. I tasted some of the fruit. It had not the slightest taste of sulphur. Mr. Chaffey told me that one place of 3½ acres has given over 5 tons of fruit. One proprietor whose place the

Company has opened and worked has just received £60 from them from sale of fruit to the Company. While these men are drying the tender fruit I cannot do better than quote to you what the *Cultivator* says on the subject, but before doing so I must refer to Mr. W. J. Allen, the expert, who is supervising the operation. He is a smart young fellow whom Mr. Chaffey with much coaxing and trouble procured from his own brother-in-law at "Riverside," California, at the salary of £30 a month. The *Cultivator* says:—"Mr. W. T. Allen, the firm's expert, is turning out several tons of fruit that he says will be equal to any thing in the world. He hauled 378 tons of apricots at Riverside, California, during 1890 season, and the papers expressed their sorrow at his leaving for Mildura because he was simply invaluable to the place, in connection with the fruit growing industry.

"When the fruit is gathered it is placed in cases holding 40 lb. This carted to the spot and placed under a sheet covered with hessian. In this shed a long table is set up, and round sit the men who are employed in 'pitting' the fruit. This is children's work—girls in particular, on account of their superior deftness of fingers, being usually employed. It is all piece work, the rate now given being 5d. per box. In California the usual thing is 5 from 7 to 8 cents (3¼d. to 4d.), and in future seasons, when larger quantities will be handled, and children will be mainly employed, probably this will be the ruling figure. The operation of 'pitting' is very simple.

"A knife cut is made round the fruit on the suture thus dividing it into halves. The two pieces are separated, the "pit" or stone is dropped on the floor, and the fruit is placed cut up on the drying tray. This is the ordinary raisin tray. When filled the tray is put in the fumigator, which is a wooden structure of two rooms, each 10×10 feet, with walls 10 feet high. The building is constructed so as to be readily taken down, and transported in sections; but when erected it is almost completely air-tight. The trays are stacked one above the other till the room is full, and then the sulphuring is commenced. About 4½ lb. of sulphur is used. It is placed in an iron tray standing on the floor, and ignited. The doors are then closed, and the sulphur smoulders away for about five hours, and the fruit is left exposed to the fumes for about 12 hours in all. The sulphuring process fixes the juice and flavour, and imparts a clear and bright appearance to the dried products (produce?) It also destroys any minute insect that may be about the fruit, and minimizes the danger of attack from weavils. When the trays are taken out the fruit has become very pulpy, and tender to the touch almost as if it had been cooked. The trays are spread out in the sun and the drying process then commences. It lasts from 3 to 6 days according to the weather. Then the fruit, which has by this time shrivelled into gelatinous looking chips, is packed in sacks to be afterwards sorted and put up in fancy boxes of various handy sizes."

We drove away, and I asked if drying machines such as the "American Evaporator" would be necessary. "Only for the last of the crop we will need something of that sort I think." I asked if he meant staying on or eventually leaving the Company. That was rather a "home" question, and he pointed to his "crib" which we were passing again. "I know something about furnishing a house, and I don't mean to spare money in this, and it looks as if I meant staying, because I couldn't expect to find a man fool enough

to give me my price for it. We have to start the Agriculturist College and put settlers in the way to understand everything for themselves." He regretted it was such a beastly day. Such days were very rare, and it was exceedingly unfortunate. I remarked that the settlers looked healthy. "Yes, our death rate is the lowest in the world, but we have a large number of healthy young men." I said I noticed there were no liquor-shops. "No, they are not allowed. The boys have a little now and again, but the absence of public-houses removes the temptation from those who would drink if drink were handy. Of course anyone can bring and keep liquor, and have their liquor, but there are no licences to sell liquor on the settlement."

I said I had examined the soil where it was wet, and Mr. Chaffey said: "The wonderful thing in the soil here is that however wet it may be it is always in a perfect mechanical condition. It does not, and will not for a very long time, require manure. Now I'll take you down to the brick-works if you haven't anything better to do." The trap had driven up to the "Office," and the manager, an American, jumped in and we drove away down past saw-mills busy sawing up huge logs, and so on along the flat by the river. At the brick-works a huge kiln was being emptied into a huge dray drawn by a pair of horses, and another kiln was in full blast. Large quantities of hand-made bricks were being dried, but a "pug" or brick machine driven by an engine was being put up which would turn out 10,000 to 15,000 bricks a day. I said: "I suppose you have a ready sale for bricks among the settlers." "Well, not much as yet because we have lost a good deal of money trusting to men who pretended they knew brickmaking on a large scale—and we eventually had to learn the thing ourselves." A little sawdust was mixed among the clay. I suggested that Mangalore tiles would make a good roof. "I have heard of something of the sort but I have never seen a sample."

I returned to the "Pearl," and as I looked at the workshops and Coffee Palace, &c., &c. I began to realize the wonders of the place. I passed an uncomfortable evening and turned in early. But I took a stroll to look more minutely at "the crib." Mr. Chaffey's villa was worth a close inspection. The grounds are beautifully laid out, and a fountain is placed in the centre in front of the steps. The white balconies relieve the red brick walls, while the rich green of the buffalo-grass and the varied flowers in the beds and neat iron railings round about altogether formed a very pretty picture.

Next morning after some time I was able to find Mr. Chaffey disengaged, and he immediately arranged with his manager to let me see something more of the place. The steamer had to leave at noon so I had not much time. The manager took me down to the stables, and there "Fred" got ready a trap and pair and away we went spanking behind a pair of young gray maros that were being broken in for Mr. George Chaffey. This was a delightful day in strong and pleasant contrast to yesterday. The cool crispness and bright sunshine presented everything in a better aspect, and one's feelings rose in harmony with the happy surroundings. Away we went along the wide streets rapidly filling with shops and houses; past unoccupied blocks lying waste; past the nurseries of the firm; and then we rapidly got into more open country saltbush plains, across which a long aqueduct composed of corrugated iron sheets bent into a

trough supported by heavy wooden trestles was made to take the water across these low-lying plains to higher ground beyond. At last on the river bank we arrive at Lord Ranfurly's property which consists of 220 acres all in cultivation. After passing through the gates we drove along having the Murray on our right, and on our left were fine apricots, the biggest, I think, I had seen; and the ground splendidly kept. We came to the engine-house, for this property has its own pumping plant which will be taken over by Lord Ranfurly. The place used to be worked by Lord Ranfurly's own manager, but he eventually put it in the care of the Company. He has picked about a ton an acre of fruit. We came to the gate opposite the house or bungalow, and when we got through the gate I inquired of a "planter" coming along with his coat over his shoulder whether we could drive in for a bit. "Oh yes, just across the next channel you can turn up through the plants and you can see the big lemon trees and see over the place." We started along the beautiful avenue lined on both sides by lovely pepper trees with their light feathery foliage and red clusters shewing prettily here and there. We turned and drove along between the wide rows, and had now on our right a fine billabong or lako while the river was on the other side of the plantation to our left. We drove right up and turned back, the heavy going taking the "grease out of the grays" as the driver put it. We were soon spanking along back again to catch the steamer. The driver very kindly took me round a bit, and we might have made a much longer round as the steamer did not leave till 2. I stepped on board the steamer ready to turn back to Melbourne.

One old gentleman with whom I had a long conversation that morning gave me a lot of useful information. He is a wine-grower himself, and he has been up at Mildura for a fortnight seeing things for himself. He said: "Don't you make any mistake. There's no mystery at all. The chief thing is commonsense. That goes a long way. Of course money, brains, and experience are needed to work the thing." I told him I had been a planter for 18 years. "Ah well you're an expert and you'll find little difficulty. Look about you a lot before you select. There's no hurry, as you don't plant till June. That block of Isard's is a good thing to start with to show you the style of land. That's fine soil. In fact the whole of the place is full of manorial property. It is as rich as it can be. Down with us we have a good deal of rain compared to this, and that often brings mildew and causes the grapes to burst, but here with this grand dry climate you ought to succeed. You don't want to flood the land. The sulphur fumes keep the fine bright colour. Find out the proper method and then dry and pack into cotton bags, and there you are. Avoid the lowly parts and watch if the soil bakes. For fruit you want a light sandy chocolate soil, and for grapes a marly limy soil. You can get what you want. It is all good. I haven't been at the office, I've been poking about, and some of these 'touts' and 'land agents' find me a hard nut to crack. They find I know more about them than they do of me. I am going in for a good bit, and I'll bring my men and horses and work myself. I could put you on to a good thing if you are going in. It will be all right when your hands are hard. See mine. I've done my share of that, but we're not slaves. I take a trip to Tasmania or anywhere for a holiday. There's Col —"

an East Indian army man, why, he goes out with his men and works like any of them." I asked what he thought if the Chaffey's cleared out. "Clear out! why they are dipped themselves too heavily to clear out. They *couldn't* clear out, if they wanted; for one thing—there is the 10 year instalment system. Every holder of an acre has a share, and they are all in the same swim. Then as to the markets. I went over to California myself to get the real truth, and they have never been able to touch the markets there and it is not likely that we will do so here. The Chaffey's, or you, or I, for that matter, won't see this thing out." We had a look at the ploughs. I asked what he thought of them. "Grand work—opens the land to let the water through. The grading or levelling is only necessary if the land is uneven. For irrigation you must have a gentle slope. I am delighted with the place."

We started about 2 and left the "Ellen" almost ready to start down the river. In a short time we reached Psyche Bend and, while I was looking at the men putting the machinery in its place, Mr. Chaffey turned up with two others and wished me "good-day." He asked me how I liked Lord Ranfurly's place. He called out to a settler who was going up in the boat: "This big chap will give you all the water you'll ever want down there." Away we went again, and as the evening closed and the sun sank low behind the dead ringed gums we would pass a few horses, or huddled groups of sheep moving in towards the gloom of the gums, and always the white "scut" of the cursed rabbit. The harsh irritable scream of the cockatoo, and the silent rapid flight of the ducks, constantly diverted the attention.

Let me make a few more notes. A passenger travelling in the boat, having found business not prospering, has just purchased 12 acres for £1,000. They are just in bearing, and the place ready for residence. That is the short cut dodge, but it needs a lot of money. Another passenger has failed in mining and means now to put his block to some use and so settle in Mildura. A Captain Stokes, a retired officer, in a copy of a letter shown me by a lady on board the "Ophir," writes: "There is not the least doubt but that the scheme will be successful far beyond the imagination of its founder." He then quotes the success of Messrs. Isard, Hodge, and Skene. Then: "As for myself I am hard at work either felling trees for fence posts, digging holes for these posts, or clearing the land of sticks after the plough, this last work being the hardest of the lot. My health has so improved that notwithstanding no previous training or experience of any kind I have felled 52 (fifty-two) trees in a day (note: pine trees about the thickness of a man's leg), and from these trunks made fence posts—not so bad for one nearly 52 years of age, and who was in poor health when he left England in May last. I can safely say that any young fellow, or old fellow, for the matter of that, with any go in him, would do well here—should he in addition to his passage money be in possession of a little capital, say from £100 to £200, and coming out shortly, he would in a few months be able to clear a ten acre block and have it ready for planting by next winter—June to September 1892—this too with very little expenses beyond his own labour."

Now what have Messrs. Chaffey done in California? "The Messrs. Chaffey are natives of Ontario, in Canada, and they have for the last 10 years been carrying on irrigation enterprises in Southern California. Their first experience

of Californian fruit-growing was at Riverside one of the most successful irrigation settlements in the State. They were not the founders of Riverside, but they gained sufficient local experience there, as well as confidence in the business, to induce them to make a large venture on their own account. The Colony of Etiwanda was accordingly established, and in addition to being a highly successful enterprise, it laid the foundation of the scientific system to be adopted in all subsequent operations. From the first the Messrs. Chaffey had given careful study to the science of irrigation, and at Etiwanda one of the principal objects kept in view was the carrying out of experiments calculated to solve the difficulties connected with various branches of the subject. In due course, and with a rapidity unknown in Australia, the colony of Ontario was founded in San Bernardino County the new settlement being called after the native place of the founders. The model colony of Ontario has been described in Mr. Deakin's report upon irrigation in America, and by the Special Commissioner of *The Argus*, who accompanied him on his mission. It was one of the boldest ventures of the kind ever made in America. It was conceived upon a scale, which, for liberality and wisely directed enterprise, has never been equalled before or since in California, and it has proved highly successful. An interesting feature of the Ontario enterprise was the establishment of the Chaffey Agricultural College. The College was endowed by the Firm with a gift of land, valued at the time at 100,000 dollars (£20,000). A sufficient area of land was sold to build the College, and the value of real estate had increased so much, that the remaining endowment was then worth as much as the original gift." "Begun no longer since than 1882, the settlement (Ontario) is at this moment in a remarkably advanced and prosperous condition. Upwards of 2,500 settlers and cultivators are already located upon it. Some idea of the speedily achieved results of whose capital and industry, combined with the irrigation works and other advantages and facilities created and furnished by the money, skill, and energy of Messrs. Chaffey may be gathered from the following interesting account by Judge R. M. Widney of Los Angeles. 'Ontario cannot be fully pictured with the pen as it was, is, and will be, without first filling in the background with sketchings of California generally. The early mariners, who gazed upon the brown landscape of valleys, mesas, and mountains, saw nothing desirable, and sailed away to other lands in search of gold and health and cereal riches. The rivers ran over golden sands. The mountains had built into their foundations the shining yellow ore. The gold-hunters came and climbed every mountain, prospected every ravine, river, creek, and hill, and camped on every plain on the Pacific Slope from the burning south to the cold north. They said the land was only fit for gold, that it was unhealthy, barren, and unproductive. When the gold was gone they disappeared from the fields that to them were void of further use. They saw not the transmutation of the products of the soil into gold. The rivers run golden sands, and over the golden sands run rivers of gold, into golden lands. The agriculturist and horticulturist came, and by handling the elements as nature intended that they should be handled, they attained results in rapid growth, luxuriant products, and prolific yield that were marvellous. The land that was supposed to be worthless was demonstrated to be of the most productive quality. On to the dry plains and mesas man

turned streams of water, &c., &c.

"Messrs. George and William B. Chaffey came to this land of developing and undeveloped wonders and settled in Riverside, San Bernardino Co., gave their time, money, and thought to the problems of this new land.

Mr. Deakin writes: "In one enterprise, at Ontario the proprietors have laid out nearly £100,000 upon 8,000 acres of land, bought at 28/ (twenty-eight shillings) an acre. There is a double avenue running through the colony seven miles long, in a straight line and 200 feet."

Judge Widney says: "The value of property is fixed and made by the combination of circumstances which nature and money have produced—productive exhaustless soil, abundance of water, irrigating dams, ditches, tunnels, pipes, avenues, hotels, railroads, colleges, health, civilization, good society." Messrs. Chaffey Bros., Limited, will clear of timber by pulling out trees &c. by traction engines; they will plough or scarify and cross-scarify the land to a depth of 18 inches; they will "grade" or level the surface to a uniform slope by passing an implement drawn by four horses over the ground. This implement need is a wooden scow 6 feet or 8 feet wide by 2 feet broad with a back board some 6 or 8 inches. Coffee planters can remember the board used by coolies when heaping the coffee on the harbooc. A big thing like that is run over the loosened earth and the whole land is smoothed. Messrs. Chaffey Bros., Limited, will line, hole, supply plants, plant, weed, and irrigate up to the time when the place is yielding fruit, or as long as is wanted. They will do as much or as little as required, and they charge high for splendid work. I pin on the "memorandum of terms and conditions of sale," which please print *in extenso*.

But your planting readers will have observed that if 2 or 3 Ceylon planters or Anglo-Indian Army men or civilians,—if 2 or 3, or 6 or 7 combine and take adjacent blocks, even one of the very far back blocks, by their united labour they can save very much of those charges in Messrs. Chaffey Bros. Estimated Expenditure. Estimated Expenditure! Surely a Ceylon man knows how to estimate ahead. He's had to do it and it has saved him often. Put in your own work, and your wife and daughter can help, if you have them, into clearing, fencing, levelling, holing, and planting—it is only 10 acres a man. Your back may ache, your neck may be scored by sun-wrinkles, your hands may be swollen, blistered and painful.—But you need be beholden to none; you have no native near to render it impossible for a white man to be seen working; the sun, though hot, though terribly hot, is not the sun you have been accustomed to—a deadly enemy,—no, it is a warm stimulating friend. The climate is not enervating or exhausting. It is bracing and dry. Then there is the keen relief of the virtuous feeling which comes after earnest effort, accompanied by substantial and tangible results. One's home is sure, and one's work is around him. Here the gentleman toils alongside the labourer, the lady washes the dishes while the "girl" makes herself otherwise useful. This is a real Utopia, a true republic, where all are equal and the only difference is in brain-power; there is only one policeman. Mildura is a separate shire and has its Police Court, but there is very little use for that except to settle civil cases. It has its cricket club and one or two churches, and a number of fine shops, and many boarding houses. Those who built on their town lots are making a fine harvest with boarders now.

Now as to profits and products:—Will it pay? Let us quote "F. W. W." in the *Sydney Herald*, Oct. 1890.

"Will it pay? That is the question of questions affecting Mildura. At the outset it may be noted that the success of this proprietary venture is inextricably interwoven with the success of the individual enterprise of the cottlers. The Brothers Chaffey, and those joined with them in the founding of the 'colony' cannot make a huge profit at the cost of disaster to the men whom they have led into the mallee scrub. Before the settlement has reached such dimensions as to return the company's outlay, and a fortune besides, the question of the profitability of intense culture under irrigation will have been answered decisively. Should it be answered in the negative, the progress of the undertaking will be at once arrested. The basis of the company's operations is one which involves the commercial interests of the owner of every properly cared for vineyard or orchard. No attempt is being made to obtain a return of the outlay before Mildura produce has been tested in the markets. Work has been planned on massive lines, and is being carried on in a bold and confident temper. The expenditure can only be justified by the success of the experiment. Should intense culture at Mildura turn out a failure, the heaviest losses will fall on the founders. That is how it ought to be in all such ventures."

Here are figures showing the increase of shipments of fruit in California in eight years:—

	1880. lb.	1888 lb.
Fresh fruits	3,141,500	53,741,670
Dried fruits	412,480	19,759,140
Raisins	661,660	16,884,570
Canned fruits	6,707,650	39,281,340

"Bradstreet" is quoted by "F. W. W." and I will quote him now:—"At Riverside, the leading orange town, the owner of an orchard of seven acres of twenty-year-old seedlings avers that last year the net profit therefrom was 1,000 dollars an acre, and this year 1,200 dollars. Groves twenty years old, however, are scarce, few even are ten years of age. Of gross profits another grower says that his budded trees yielded the 3rd year in the orchard 150 dollars to the tree; the 4th year 3 dollars to the tree, or from 300 dollars to 375 dollars to the acre; eight-year-old buds 10 dollars to the tree; and nine-year-old buds 15 dollars to the tree, or 1,125 per acre, counting the fruit worth only one dollar per box on the tree. A third man reports 40 acres of oranges planted 8 years ago, and yielding this year a net income of 12,300 dollars; and another 25 acres of oranges and lemons ten years old that net 500 dollars an acre. For Riverside, as a whole, the following statement was made before an official committee a year ago:—

"Riverside has 3,000 acres of orange orchard, a portion of which is yielding good crops, a portion of which is yielding partial crops, and a portion is not in bearing at all. These 3,000 acres this year produced 1,000 car-loads of oranges and lemons, worth on the track an average of 750 dollars a car-load or 750,000 dollars—about 250 dollars an acre. This is not picking out sample orchards, but averaging all the orchards, whether bearing or not."

And so on as regards California. Now for Australia and Mildura. The great point is that Australia can supply Europe and America when they are bare of supply. Thus America may be a large customer, and as you will understand, good prices will be realized when the local supply has stopped. I had intended going into the local and European market-prices, but anyone wishing to ascertain this had only to write to Messrs. Chaffey Brothers or their agents, and full particulars will

be furnished. Suffice it to say that the market question has been practically thought out and considered, and the results of the calculation are reassuring.

Then as to *blights*. The locust is the chief enemy; the rabbit can be kept at a distance in "intense cultivation." But pests are not so common or deadly as under a tropical sun, and in a community like Mildura combined effort will be effectual.

As to transport. The Rivor Murray is wide enough, and besides this a railway will yet be made through Warrackmabeal, and this will enable growers to send table-grapes and fresh fruit to the Melbourne and Adelaide market quickly. Mildura must have a railway. Then in such a large community buyers will come to them, to their doors—nay they will purchase the fruit on the trees, and all the grower has to do is to sit in his arbour and count up his money like the "King" in the nursery rhyme.

For *Facts and Figures* beyond what I have given and in confirmation and support of what I have given, I refer all to Messrs. Cheffey Brothers, Limited, Swanston Street, Melbourne.

And now in "conclusion," as the padres say.

I speak to Young Men. Is this not tempting? The problem that has puzzled your "governors." "What will we do with our boys?" is fairly solved. The expensive "Army," the tedious "Office," the doubtful passing into the "Civil" with its few "plums;" then the "Church" for whom so few are fitted; then "Planting" in India and Ceylon. Tea, Indigo, Coffee? Who are making money? Ask the veterans. Here you can use your superfluous energy; and your youthful buoyancy will carry you over the toil. You will have many congenial friends—public school and college men—all working, and all happy.

I speak to Middle-Aged. Merchants sick of bad times, hopeless and despairing in the struggle, with wives to think of and helpless babes to feed. Gather the fragments of the wreck and come here to easy yet constant labour. Your wife and children can help you in a hundred ways, around you can make many friends of men in your own condition.

I speak to our Soldiers—whether the grizzled and tanned officer, pensioned off with many years of work in him, which will be shortened by the spirit wearing out the case, the bird beating against the wires of the cage, the man accustomed to all the life and energy of active work in India suddenly condemned to aimless wanderings, with a "Trichy" cheroot and overcoat, in a busy world where only children and nursery maids are idle. How often has the Anglo-Indian officer turned with a longing to Tasmania and repented at finding it a country without "go"? Here is a paradise. Write and inquire.

And to my Brother Planters of India and Ceylon. I have spent long years in both countries, and as I looked round this land of promise I thought of you with your dark future, dark past, and what sort of "present"? Your ladies! poor pale miserable strugglers against a climate which is specially pernicious to those who have no active out-door occupation. *Your wives and daughters!* See them here with deep sunbonnet and gloves to protect their delicate skin, daintily turning the water down the rows, carefully picking the grapes and leaving them on the trays between the rows to dry into raisin. They would have cheap horses, and agreeable friends, for there are many ladies here and horseflesh is cheap.

And to ladies, old or young, without a protector of the stronger sex—you can have your garden and bower, your villa-block, your township-block, and have all these things under your own eye—easily procuring hired help.

There is already marrying and giving in marriage in Mildura. Now I must leave the theme—and the steamer, as I am now at Swan Hill on Saturday morning. A long day's journey brings me back to Melbourne at half-past eleven in the evening, so that I have been exactly a week away. I had two hours to see Bendigo the great sunny centre—but I must postpone further particulars to another time.

ABERDONENSIS.

HEMELEIA VASTATRIX.

* * *
There will be probably a difference of opinion among the planting community in regard to the disclosure of the Government of Madras. We must confess that we agree fully with the wisdom of it, as the opinion expressed by Dr. Cunningham, a scientist of the very front rank, is supported by many planters of long standing and great experience. For sixteen years or more experts have been engaged in the investigation of this disease, and so far the practical result has been *nil*. This in itself would argue nothing, as after all it is only just now that the causes of many diseases in the human frame have been discovered and the proper prophylactics prescribed. But with the comparatively small interests at stake we cannot believe in the wisdom of incurring a vast expenditure on the possible chance of discovering an infallible remedy in the face of such an opinion from such a man as Dr. Cunningham. The planting industry is prepared to pay a fortune to a man who can provide a certain cure, and during the past twelve months we have been assured that such a cure does exist. When the discoverer was pressed to tell us something about it all we learnt was how to mix manures, dig drains and prune. Such is the usual finale of the boasted infallible cure. The disease has now extended throughout every coffee district, and wherever it has been checked or stayed, it has been due to the precautions taken by the planters themselves. It is an undisputed fact that it has spread through the jungles, and unless there too it is destroyed, nothing can insure immunity for the fields of coffee, or prevent propagation of the mrellicus spores. It is unsatisfactory to have to form such a conclusion, but it is idle to hope for the millennium yet awhile, and, if the lion cannot lie down with the lamb, there is no need just yet to anticipate a scarcity of mutton. So, too, in a large measure as regards the coffee industry, greater care and attention must be bestowed on the choice of locality and the cultivation. Under unfavourable circumstances the disease will doubtless assume the form of an epidemic, but so long as preventive measures are carried out and the weather does not become abnormally unfavourable to the plant, dire results need not be anticipated. It would, we believe, be wise if the Planting Associations of the different districts were to obtain from some of their oldest and most practical planters observations of the disease and the measures taken to check it, showing which they found most effectual. In some districts one remedy will be found the best, in others a different one. If such observations were carefully collated and edited by a gentleman with scientific knowledge, we believe that it would prove a hand-book of inestimable service to planters in contending against this disease and in mitigating the evil effects of an attack.—*Madras Times*, Feb. 12.

PRODUCER AND RETAILER.

Within the last few weeks a very keen discussion has taken place in certain English journals concerning the advisability or otherwise of retailers growing their own tea. In a letter that appeared in the *Grocer*, mention was made of a large Ceylon Tea Plantation Company, which paid dividends at the rate of 15 per cent and the question was asked why with such brilliant results plantations should not be owned and managed by a combination of retail traders in

the form of a limited company, thus saving not only the wholesale dealers' profits, but also that of the planter. To talk of saving the planter's profit is ridiculous as the profit will, of course, still exist whether the produce is purchased by a stranger or by the owner himself in his capacity as dealer for the profit of the proprietor of the plantation is only that margin which exists between the working expenses of the estate and the amount realised by the sale of the produce, the purchaser being quite immaterial. Whether the company chooses to pay a dividend on its estates, or on its retail shops is for itself to decide. It is merely a question of book-keeping. Perhaps the most forcible argument that has been adduced is that if the consumers can be truthfully told that their grocers grow their own tea, and, therefore able to sell them a better article at the price than the shop across the way, this dictates of commonsense will induce them to believe it and the trade of "retail-growers" will consequently be increased. Against this argument, however another correspondent writes as follows:—"Another phase of the question of tea-growing, which perhaps furnishes the most powerful reason why retailers should consider well before entering on such a course, is the fact that, buying on the open market in combination, dealers will invariably be able to select more suitable goods from an assortment furnished by between thirteen and fourteen hundred gardens, covering an area at the present time in India and Ceylon of upwards of half-a-million acres."

The latter argument, is in our opinion, the stronger, and we think it very doubtful whether larger profits are likely to be made by a Company in a dual capacity of estate-owner and retailer, which is obliged itself to dispose of its own produce to consumers, than would have been shown separately by the planter and the grocer. Certain teas may and do secure an enhanced value for the very reason that they blend well, and, if sold alone, would not fetch anything like the same price. A clever buyer of tea in Mincing Lane, has given it out as his opinion that he can buy to greater advantage in the open market than he could if he invested his capital in and took the risk of tea gardens about which he knew next to nothing. The converse holds equally good, and the planter who opened a shop in his native village or even in "that little village," London, is more likely than not to realise smaller profits than if he had sold in the usual way. Certain planters have, if we do not err, succeeded in working up a good retail trade for their produce, but still we maintain that the rule holds good, and it would need a bold planting man to seriously contemplate turning grocer or even broker. Mr. Llowellyn-Jones, a planter who has tried tea growing and tea retailing in combination in the course of a long letter, points out that teas of every grade and description often get into the hands of the retailer for less than the cost of the producer. So far as one has suggested that the grocer should grow his own coffee, doubtless because it is necessary to keep in stock so many different grades and qualities, Brazil, East India, Guatemala, &c., and it is chiefly by the judicious mixing of these different growths that profit is made. In fact at the present time tea is the only plantation produced in connection with which such a scheme could have been mooted.

The question which this dissection naturally suggests is how long it is wise for the planter to keep his interest in his produce, or when for his own sake it is best to sell. As regards tea, the nearest market to Southern India is practically London, for with the exception of the small quantity that is needed for local consumption, there is no demand for tea and no salerooms in Southern India such as exist in Calcutta and Colombo. The same may be said about cinchona, for though each year merchants on the West Coast dabble a little in bark, the demand is so small that it is to all intents and purposes *nil*. Pepper will always find a ready sale in this country, but it will be some few years yet before this spice figures as anything but a very minor product when taking into account the whole industry. On the other hand a brisk trade in plantation coffee is carried on every season, and the planter is always able to dispose of this produce locally

if he wishes it. When sales were made in this country formerly, the system that everywhere prevailed was to sell on *f. o. b.* terms, and in most cases the purchasers were the buyers, and in the sales notes a certain percentage of triage was laid down. Planters may be forgiven then if they declined to believe that the merchants were sufficiently above the rest of mankind not to regard their own interests before the owner of the coffee. Consequently, unless a man was pressed for money, sales were low and far between, the planter preferring to take his chance of the open market at home. Lately, however, a new system has been introduced, where the purchaser takes delivery of the parchment at the planter's store and when the latter has received his money, all interest in his produce at once ceases. There is, we consider, little doubt that unless a man is a large proprietor, this is the best course to pursue so long as he can obtain a fair price for his produce, provided always that it is understood that he merely sells his coffee and not the name of his estate. This is a very necessary stipulation in view of his making subsequent shipments on his own account, as the purchaser, when he buys a small crop, is certain to mix it with other coffees. We hold that, all things considered, the planter who has a small or medium-sized crop, protects his own interests best by selling to the purchaser who will give him fair value and will take delivery of the coffee at the estate store.—*Madras Times*, Feb. 23.

BORNEO PLANTING NOTES.

Cocoanuts in North Borneo bear in five years, and the betelnut palm in four years, but the demand is so great that coconut trees in bearing in Sandakan let for \$2 a year each. We understand that Mr. Abrahamson has leased 500 acres at Kudat for a coconut plantation.

The experimental planting of cotton seed in the garden at Government House by His Excellency Governor Oresag, and the success attending the same, was made known to our readers at the time. A further development is now being made of this industry by the Government, who are now distributing seed of a very high class of Sea Island cotton of long staple called the "Allen" variety a supply of which was arranged for by the Commissioner of Lands when he visited Liverpool in the early part of this year. The information then obtained by Mr. Walker was of such a nature that the Court of Directors authorized a small expenditure on seed, and on a cotton gin which lately arrived and has just been fitted up by Mr. Walker at Kudat. We understand that at the suggestion of the Acting Resident, Mr. R. M. Little, His Excellency the Acting Governor has authorized the purchase of a small quantity of clean cotton in order to stimulate the industry and to ensure a fair sample being obtained for the information of the Liverpool market. Mr. Walker informs us that the expense of production in the United States is about six cents per pound, and that the value of Sea Island cotton in the English market is somewhere about the round shilling. Four pounds of cotton yield no pound of clean cotton and three pounds of seed, which last is worth £7 a ton in Liverpool. In Ceylon the seed, mixed with coconut poonac, is given to the cattle or to the pigs, and our Chinese should bear this in mind, as cotton seed is well known for its fattening qualities.

The Commissioner of Lands has just returned from visiting Kudat, and informs us that the advancement of agriculture by the Chinese settlers is becoming very noticeable. The banana cultivation has now increased to such a degree that, unless some outlet be found for the sale of the fruit, it will cease to be profitable. Mr. Walker made a trial purchase of 443 bunches of bananas at six cents a bunch and found a rapid sale awaiting them at Sandakan at ten cents, which were retailed at from twenty to thirty cents, and we understand that the two men in charge

of the fruit have made arrangements with local shopkeepers for regular consignments of fruit from Kulat. On one point of Mr. Walker lays stress, as upon it the success of the fruit export trade depends. Two baskets of pineapples arrived crushed and unsealable, and the storage of the bananas on board the steamer was capable of improvement, as the fruit ripened too rapidly and caused a waste. Doubtless our shipping friends will see to this as we believe a very little encouragement is required to enable a very large fruit trade to be opened up with other ports than Sandakan where fruit is notoriously dear and unobtainable. Mr. Walker speaks with admiration of the coffee planted by the Hakkas at Kudat and of the orange and lime trees with their golden fruit and also of the roads lately made by Mr. Little, the Acting Resident, but adds that, unless carts are introduced, it will be impossible to transport the fruit. Much the same may be said of Sandakan, where enterprising Chinese complain bitterly of the cost of coolie transport.

A few sago trees are being cut down and worked on the Beatrice, and the operations in connection with sago making may be seen in progress on a small scale in the centre of the race course. These operations though curious and interesting, are not calculated to increase one's fondness for sago as an article of diet. These being the first sago trees cultivated on this coast, their coming to maturity marks a new departure, and, now, it is seen how successfully sago can be grown it is to be hoped that sago planting will be taken in hand seriously, more especially as the price of sago is very high now, and as it depends largely upon the price of flour for which it is used as a substitute, there seems every probability of its remaining up.—*B. N. B. Herald*, 1st Jan.

MINOR INDUSTRIES.

A BARBADOS SHOP IN LONDON, NEW YORK AND MONTREAL PROPOSED—AN EXAMPLE FOR CYLON TO FOLLOW?

In face of the increasing competition to which our staple, sugar, is being subjected—in face of the continual displacement of the Cane by the Beet, it seems to us that we should take steps to foster other industries on which we might fall back, should it ever be our misfortune to find the production of sugar unprofitable. It is of no use, however, for us to know how to grow this and that vegetable or fruit, unless we can convert it into a marketable commodity. And we must first create a demand for our minor products; otherwise they will not be forthcoming in sufficient quantity and of sufficiently good quality to amount to much in the sum total of our exports. How shall we develop that demand? how shall we get it ready beforehand to meet our possible want some day of a market for other of our produce besides sugar?

We have a suggestion to offer. It is, that the Government should subsidise the maintenance of a small shop in some part of London, and later in New York and Montreal, where fruits, vegetables, preserves, pickles, fancy work, any anything else we can produce might be sold, with the proviso that all goods sent to such a Barbadian depot should first be sampled here and seen to be of good quality. We might thus in ten or fifteen years establish a reputation that might be most serviceable to us in the future. It is important that none but the best class of preserves of fruit should be on sale at such a mart. Tamarinds, as preserved by us for our own use, are delicious; as they are sold in the London shops preserved in molasses, they are far from this. At present the demand for preserved tamarinds fluctuates. One year someone will make money off a speculation in this article; the next year he will sink his gains. What in our opinion is wanted, is a continuous demand for a properly preserved fruit—

with the brand *Barbadian* on it as a guarantee of its quality.

There are many of our minor products that would take in England, if properly pushed and advertised. Cassava cakes, for instance. We have repeatedly sent them to England and received most hearty expressions of thanks in return, and assurances of the way in which they have been enjoyed. We are assured that if people in England knew of the existence of these things and knew where in London they could go and get them of the best sort, there would be a large demand for them. And an acre will give a deal of cassava. Cassarepe fetches in London some six shillings for a small bottle. Guava Jelly is appreciated by English people when it is well flavoured with guava. As a rule they think it too sweet and tasteless. It might become for us as proper and extensively used there as pine apple jam is.

Next take some of our fruit. Oranges are there in abundance. We should gain not very much perhaps by those, unless we could put them fresh in the market at a time when other sources of supply fail, but we have Shaddock. Now English people know little of Shaddock. But who, that has tasted a *Swan's* Shaddock, would hesitate in pronouncing this as incomparably the best fruit we produce. There are Shaddock and Shaddock. Some dry and bitter, some juicy and delicious. It is besides a fruit that keeps admirably. We all know that. Speaking with an old planter a week or two since, he assured us that a friend had written from England to tell him that a Shaddock he had sent as a present, was still good at the end of three months. We queried some mistake in this, but were assured it was the case. Three months is a long while for a fruit to keep, but we can readily believe Shaddock would keep long in England. And they would be largely bought, especially the claret variety, if only pushed and advertised, and none but the best varieties suffered to find their way to the Barbados Mart.

What is the use of our yearly display of jams, and jellies, and preserves, and fruit and vegetables, and fancy work at the Agricultural Society's Exhibitions if we do not endeavour to turn these things into marketable commodities? Yams are much appreciated in England, though they do not keep well there; good sweet potatoes are also appreciated. Of eddoes they have never heard. What a nice thin soup eddoes would give for a change, if they only know of it!

Attached to this Barbados mart should be a small Restaurant, where our vegetables properly cooked, with our fruits and preserves, might be tasted. What a boon it would be to a West Indian straggler in London to have such a place to go to! A small subsidy—the rent of the premises say, might be sufficient to induce some energetic person to take the matter up and push his own interest and ours together by conducting such a Barbados Mart and Restaurant, in Holborn, or wherever else thought best.—*Barbados Agricultural Gazette*.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, Jan. 27th.

CINCHONA.—The periodical auctions which took place on Tuesday were the heaviest that have been held in London for several months. They included

	Packages.	Packages.
Ceylon...	1,138 of which	1,112 were sold
East Indian ...	1,345 "	1,208 "
Java ...	85 "	31 "
South American	1,017 "	347 "
African West Coast	123 "	123 "
	3,703	2,821

The barks were of fair quality, though there were a few lots of an unusually good character. Among the Ceylon bark yellow varieties were better represented than usual. At first the sales showed a decidedly firmer tendency, and there was a strong competition for almost all parcels. This firmness was maintained while several catalogues were being sold, but towards the end there was a decidedly easier feeling, and on the whole the sales showed no improvement over the last London auctions. The unit remained at from 1½d to 1½d per lb. It is noteworthy that several hundred packages of East Indian and Ceylon bark, imported four or five years ago, were sold today.

The following were the quantities purchased by the principal buyers:—

Agents for the Mannheim and Amsterdam works...	247,679
" Brunswick works	128,513
Messrs. Howards & Sons	83,954
Agents for the Amerbach factory	74,950
" American and Italian works	45,790
" Frankfort O/M and Stuttgart works	39,410
Sundry druggists... ..	40,553
Total quantity sold	659,045
Bought in or withdrawn... ..	134,588

Total quantity of bark offered 793,613

QUININE.—Towards the close of last week the market recovered somewhat, and 15,000 oz. second-hand German bulk sold at from 10d to 10½d per oz. on the spot, after which holders refused to make any more sales at that price. Early in the week the market again became firmer, and sales of 20,000 oz. German bulk, second-hand were announced at 10½d to 10½d, with further buyers at the higher figure. Since then the drug has remained firm with further sales at 10½d per oz. for German bulk on the spot. For forward delivery from 1½d to 1s per oz. is now asked, but these prices are as yet unattainable. There are still sellers on the spot at 10½d per oz. At last week's bark-sales in Amsterdam

Quinine (in the bark) sold at a unit of

kilos.	cents.
2,211	6
9,928	6½
3,817	7
370	7½

making an average unit of 6·80 cents. The tone of the sales was brisk and animated, and only 209 packages manufacturing barks were bought in. Pharmaceutical barks were exceedingly slow of sale, and nearly all lots of this description had to be bought in. The richest parcel of bark offered at the sales was one of 63 bales Ledger stem bark from the Kertamanah plantation, which was equal to 7·82 per cent quinine sulphate, and sold at 48 to 50 cents per half kilo. Altogether there were 231 packages of bark costing over 7 per cent sulphate of quinine.

Jan. 28th.

QUININE.—The following equivalents of quinine sulphate in the bark were bought by the chief purchasers at last week's Amsterdam cinchona sales:—Mr. Guet, Briegleb, 5,070 kilos; Messrs. Bohringer & Sons, 3,577 kilos; Auerbach works, 3,219 kilos; Brunswick, 1,707 kilos; Frankfurt, 988 kilos; Messrs. Matthes and Horncester, 968 kilos; Mr. J. de Lig, 637 kilos; Messrs. Hoppert & Hoysse, 468 kilos; Messrs. C. L. Scheyn & Zoon, 231 kilos.

TEA TO DRINK.

The following is from the Paris edition of the *New York Herald*:—

QUALITIES OF THE INDIAN, CHINESE AND CEYLON LEAF.
Too Much TANNIN.

THE INDIAN TEAS CONDEMNED—CEYLON PRODUCE
UPHELD AND THE CHINESE LEAF PRAISED.

The *Herald's* recent editorial on Tea has been very much commented upon, Messrs. Dixon, Gibbs & Co., of 17 rue de la Paix, the Paris branch of the big English firm, speaking of it, said:—"We thoroughly agree with the article on tea in the *New York Herald*. Having had Sir Andrew Clark's report on China tea sent to us, we asked his permission to allow us to have his remarks printed. China teas we have always recommended as being the most wholesome. Dr. Jonathan Hutchinson, the eminent specialist, recommends a pure China tea for invalids, and for this purpose our firm have made up a special preparation known as the *Lapsong-Souchong*. This tea is neither injurious

to digestion, nor yet causes headaches. It has none of the bad effects of the Indian teas, which are apt to injuriously affect the liver on account of the amount of tannin in them.

"Sir Andrew Clark has given us special permission to publish the following extract from his lecture delivered to the students of the London Hospital while describing the appropriate treatment of a certain patient. It applies strongly to the *Herald's* article:—

A BLESSED BEVERAGE.

"Let him," he said, 'have plenty of good feeding, and at the close of his meal let him sip a cup of milk-and-water, or a cup of tea. And here I must pause to speak to you about tea. Tea is a blessed beverage. I do not know what I should do without it. But there is tea and tea; and one of the teas which I have in my mind is the representation of all that is physiologically wicked. I go about town a good deal, holding consultations here and there; and about five o'clock, when I get into a place, the lady of the house will say to me, "Sir Andrew, you look so tired. Do let me give you a cup of tea." I say, "Thank you very much." But the tea has stood for half an hour; and she remarks, "I know you do not like it strong, Sir Andrew," and then she puts about a tablespoonful of tea into the cup and fills it up with water. Now I call it positive cruelty to give tea like that to anybody, and I hope you gentlemen will always set your faces against such a beverage.

"Tea to be useful should be, first of all, black China tea—the Indian tea which is being cultivated has become so powerful in its effects upon the nervous system that a cup of it taken early in the morning, as many people do, so disorders the nervous system that those who take it actually get into a state of tea intoxication, and it produces a form of nerve disturbance which is most painful to witness.

"If you want to have, either for yourselves or for your patients, tea which will not injure and which will refresh, get black China tea, putting in the right measure—the old-fashioned teaspoonful for each person, and one for the blessed pot. Then pour on briskly boiling water, and within five minutes you must pour it off again, or it will become wicked instead of good. Let this patient, therefore, have half a pint of milk-and-water or coccoatina, or half a pint of tea, à la Clark, if you please."

"How do you account for there being so much tannin in the Indian teas?" asked the correspondent.

"Principally on account of the lack of drainage of the land."

"And you really think they are bad for the liver?"

"Well, there is a practical proof of that in the fact that if you go to London you will find that a taster of Indian teas will receive from £100 to £200 more per annum than the one who tastes Chinese teas."

"And the Ceylon teas?"

"They are very much better than the Indian teas. We have here some very fine Ceylon gold-tipped teas, which run into as high as 40fr. the kilo. But although we keep it Ceylon tea is not very much known."

"And what do you recommend for persons with bad livers?"

"A pure Souchong."

"And what do you consider the best way of making tea?"

"No tea should be infused for more than five minutes—Chinese tea for that period, but Indian and Ceylon teas only for three or four minutes, and then drawn off."

"How do you account for Ceylon tea being better than Indian?"

"Because the conditions are better, and probably the climate has much to do with it. Ceylon has been taking the place of Chinese in some instances, as it is not quite so pungent. We use the Ceylon tea, as also the Indian, in small quantities, about 1-16th to the pound, to give a little more body to the Chinese teas.

"Do not keep your tea. It increases in weight and decreases in quality. Use fresh water from the tap, and not water that has boiled. This is very important. Many people take water for making tea out of a boiler, or use water which has been boiling. That water is no use, and you cannot make good tea with it.

"I don't quite agree that Indian teas produce more liquid than Chinese, because you can infuse Indian teas only once, but Chinese twice, with good result."

"And Japanese teas?"

"At present the Japanese produce just about enough for their own consumption, but I have here some very fine samples of Japanese green tea, Hyson tea, which has never touched copper. You will see that the leaves are long. They are simply sun-dried."

TOWER TEA.

The Tower Tea Company deals almost entirely in Indian teas, although they hold in stock all other kinds. A call was made at one of their many establishments which have come as such a boon to lady shoppers in Paris. Being asked their opinion about Indian teas having a large quantity of tannin in them, they simply laughed at the idea. They mentioned as a fact that Indian teas were used very generally in the hospitals and had never been condemned, and that therefore they could not have the evil qualities which the Chinese tea-dealers tried to make out. They were rarely asked for Chinese teas by their customers. They said that in making tea they always used filtered water, and in serving it they at the same time gave a small pot of boiling water, so that the first cup of tea could be drawn off at once before it had infused too long, and a second could be made at once. The question of the period of infusion of the various teas was that in the case of the Indian teas the leaf was small, and therefore did not require the same amount of time for infusion as the larger leaf of the Chinese teas.

ANOTHER OPINION.

The manager of the Liverpool, China and India Tea Company, in the rue St. Honoré, spoke in a very interesting way on the subject of teas. He said that his firm dealt in every kind of tea, and their experience was that the good grades of each tea-growing country were about the same, and that the inferior grades of Chinese teas were just as bad as those of India, Japan, Ceylon or Java. Good tea could only be obtained by paying a proper price, and that price in England ranged from three to four shillings, and at the latter price the best of tea could be had. The Darjeeling and Assam teas were just as good as any others. He considered that Ceylon teas, although somewhat now on the market, had been very good, but that there was a tendency at the present moment in that island to produce quantity rather than quality. By this he meant that of late the Ceylon tea-growers had been getting too many crops off the plants and that there ensued consequently a lowering in the quality.

The Java teas, he said, were principally sent to the United States, and their favorite tea was the young Hyson leaf. The Japanese produced plenty of tea, but it was almost all sent to the United States, and he was willing to say that if you went on the London market today, you could not find any Japanese tea there, and that if any Japanese tea was found in England, it came from the United States. As regards the so-called caravan, or hand-carried tea, he felt sure that very little of it was so conveyed nowadays, on account of the extra expense, and that if it were little or none of it reached this country, as it would have to pay double duty.

CEYLON TEAS.

He then drew attention to an article in the *Horne and Colonial Mail* which is of much interest to the tea-drinking public and the trade. Ceylon tea, it says, is unlike the "faded beauty" that is put on the shelf when youth and freshness are past. No rival can yet replace her, although the true rich Ceylon flavour is seldom to be met with now. The bulk of this year's crop has been very poor and many of the teas have been coarse and raw burnt.

A WARNING.

In the above we have a serious warning to the Ceylon tea-growers, and it would seem to their best interests to regulate, as far as possible, the manufacture of the teas, so that the very high reputation which they had in a very short time should not be destroyed by the grasping proclivities of those who at any price wish to make money.

The same paper gives the following figures, as showing the increase of the Ceylon tea trade during the past three years on the London market. In the year 1880, about 438,000 packages; in 1890, 545,000 packages; and in 1891, about 741,600 packages, thus showing the enormous increase in three years of 311,600 packages.

LARGE INCREASES.

The *Grocer*, another well-known trade organ, in a publication of the movements of tea in the port of London, says of Ceylon tea:—"During the eleven first months of the present year the landings in round numbers, have been nearly 55,000,000lb., against about 37,120,000lb. in 1880, and 28,444,000lb. in 1889. The deliveries in the same period, it is an extraordinary fact to observe, have kept pace fairly well with this rapid increase in the imports, and have amounted to 49,203,600lb. in comparison with 34,880,600lb. last year and 28,277,000lb. in 1889, and the business still goes on expanding as fast as the crops grow larger every season. Another remarkable fact is that that while the receipts of Ceylon tea here have been augmented by close upon 18,000,000lb., those of Indian have not been rendered heavier more than 8,698,200lb., or barely half so much, and instead of the very substantial gain of 14,323,000lb. in the clearances, as shown by the Ceylon descriptions, Indian sorts actually exhibit a deficiency of 1,979,500lb. for the past eleven months. To satisfy these requirements of Ceylon tea it is reasonable to infer that there must be a constantly increasing rate of production, and it is, therefore highly satisfactory to note that the entire crop, as gauged by the estimated shipments to the United Kingdom for 1891, will, in the aggregate, reach 64,000,000lb. more than the previous season."

THE TEA DRUNK IN AMERICA.

TO THE EDITOR OF THE "New York Herald."

People in this country seem to have the idea that most of the tea that Americans drink comes from China. They are way off the track, as most of the tea comes from Japan. Japanese tea, in its effect on the nerves, is about twice as existing as the tea from China. One would naturally think that we are the last people on earth who should use such tea; but it is a fact that we here in the United States consume more of Japan tea than any other nation on the globe.

We now import more than 40,000,000 lb. of tea from Japan, and the consumption is continually on the increase. The teas of Japan are made in eight grades, and we do not get the best by any means. The Japanese are willing to pay much more than we are for tea, and they understood how to make tea better than we do. Everybody in Japan drinks tea, and every little house at the cross roads is a tea house. The hot water is always ready, and as tea is best when the water has been on the leaves only a few moments, you can always get as much tea as you want. They don't drink tea in Japan the way we do here. They have small porcelain cups, holding about as much as our egg cups, and the very quaintness of elegance is to drink your cup in three sips. The more noise you make in drinking the hot liquid the better your Japanese host like it.

There is one practice of our American groceryman that makes tea even worse than it really is, and that is buying of tea dust, which they mix with the good tea, and sell it all at the higher price of the good tea. The dust comes from the sifting of the tea before it is packed, and there is over \$150,000 worth of this tea dust used in United States. I should say that this enormous sum is all we can get,

for if there was twice as much as dust to be had the groceryman here would buy it.

About four years ago I went very carefully over many of the Japanese tea farms. You must know that tea was introduced into Japan from China about one thousand years ago. When it was first brought over it was so costly that only the Japanese noblemen could afford it, and some three hundred years ago, I am told, the Mikado had a tea officer on his staff to look after his tea gardens. Now every farm has its little patch of tea plants. The best of tea comes from Kiota, from the famous tea gardens of Uji.

A new tea plantation in Japan is started from the seed. This is gathered in October from the plant, put in a mixture of sand and earth and dampened to keep it fresh until spring. The tea plant is a species of camellia, a short, stocky bush, three to five feet high, with white, waxy flowers. Its leaves are dark green, and it would make a beautiful shrub for hedges. The best soil for a tea farm is virgin forest land, but that is remarkably scarce in Japan, and the land that has been cropped for centuries is generally used. The soil must be well drained, and it is essential that water should not lodge around the roots of the plant. Many of the tea farms for this reason are on hillsides arranged in a kind of terrace.

The seeds gathered in the fall are planted in the spring in circles about two feet in diameter each circle containing about thirty seeds, with the centres of the circles making up the garden about five feet apart. These two-foot circles in a few years form a compact bush, and each year it is carefully cultivated as well as heavily manured. During the third year of its growth the plants have leaves ready for the picking, and a tea plant is at its very best between its fifth and its tenth year. There are at least three pickings a year, and a good tea farm should yield an average of 2,500 lb. of tea to the acre.

The picking of the teas is done by girls with small baskets, which are in turn emptied into great baskets, carried by coolies to the firing room, where it is sorted, sweated, rolled, steamed and dried. The process is a long one before the tea is packed in large earthen jars to be taken to the seacoast, where it is made ready for export. The large firing establishments at Kobe prepare the tea by another drying for shipping to the American market. It is during this last firing that the coloring matter, if used at all, is put into the tea.

The idea that green tea is always colored is a mistake, as the natural color of the leaf is green and the sun-dried tea is green. The crops that are picked late in the season have not this high color, and for this reason the coloring matter is used. It consists of a mixture of incense and soapstone, which is thrown into the pan while it is on the fire. We next hear of it in the caddies of the grocery stores, where it is sold for about five times, what it costs the wholesale dealers to import it.

AN AMERICAN.

New York, January 6th, 1892.

THE reception which Canadian produce has met with in London during the past season is in every way encouraging, and should incite Canadians to new and bolder efforts. In the egg trade for instance, a remarkable development has taken place, between thirty and forty millions of eggs having been landed at Liverpool. These consignments met such a ready sale at good prices that a further expansion of the trade is expected next season. The apple trade has also assumed great proportions. The imports into Liverpool for the season were 369,880 barrels, as against 96,628 barrels during the corresponding period of the previous year. The principal portion of these supplies has been Canadian, the prices of which range from 15 to 20 per cent more than for those of the United States. So that in this particular instance at least, the American protective tariff has had the effect of promoting trade between England and the Dominion.

—Colonies and India.

SETTLEMENT OF EUROPEANS IN THE NEW HEBRIDES, AND THE FUTURE OF THE GROUP.

The day is coming when all the islands of the Pacific will be claimed as the natural heritage of the empire or republic, whichever it may be, that may finally be established on the Australian continent. When the population of that continent equals forty or fifty millions, short work will be made of the titles of the various European nationalities to islands or parts of islands as in New Guinea, or to groups of islands on the outskirts of Australia. Meantime it is, naturally and justifiably, a source of extreme irritation to the Australian colonists, who even risked a rupture with Britain in order to prevent the further introduction of convicts to its shores, to see France establishing a convict settlement in close contiguity to their free land on the fine island of New Caledonia. We may rely on it that Australia only waits until she is strong enough to right this great wrong. Meantime the French, having established themselves in New Caledonia, naturally cast looking backs on the adjacent group of islands known as "the New Hebrides." More than one attempt to annex these islands to France was made, but this was too much for British patience and the attempts were resisted and some species of agreement has been entered into for joint control under a joint commission, the settlement of subjects of both countries being allowed, but under very unequal conditions. The sale of arms and ammunition and of intoxicating drinks to the natives ought manifestly to be forbidden, and Sir John Thurston, who has succeeded Sir Arthur Gordon as High Commissioner of the Western Pacific, as well as Governor of Fiji, has stated as a fact disgraceful to the United States Government, that, but for the objections of that Government, such sales would have been prohibited to the subjects of all nations. As matters now stand the traffic is penal and punishable only when British subjects are the wrong doers, and Frenchmen who have themselves purchased large tracts of land from the native chiefs for arms, can procure and have actually procured the punishment of those connected with a British brig for carrying a cargo of arms! It says much for British enterprise that British trade in the islands should be increasing under circumstances so one-sided. Not long ago we extracted an account of the, in this case, apparently, unprovoked murder of a Mr. Sawers, a planter on Santoo, the largest of the islands. Enquiry was made by a British war vessel, which was to be submitted to the joint Commission, and in answer to complaints that wrongs inflicted on British subjects were not redressed, although wrongs committed by them were promptly punished, Sir John Thurston's answer was that those who chose to settle in the islands took their lives in their hands,—sat upon a powder magazine and must expect some day to be blown up! And yet purchases of land by settlers are recognized and regularly registered. As might be anticipated some of the aboriginal chiefs attempt to sell the same lands over and over again. Here inequality again prevails. The French adopt a tone of demand: "we want such and such land and we must have it," while British subjects are compelled to observe much more equitable proceedings. The removal of the natives from island to island for purposes of labour is forbidden, although latterly the Missionaries, who are scattered over the islands where they have done much good, have favoured a relaxation of this rule. We have a chart before

us as we write, on which a recent visitor has written the names of eleven Scotch Presbyterian Missionaries opposite the various islands, from Efate, northwards to Santo, on which they are labouring. Towards the end of last year, at the instance of Mr. Munro, the Victorian Premier, a list of "civilized" residents on the islands was compiled by the Mission authorities. The result was thus stated:—

There are 103 French residents at present on the islands, and 2 who are absent just now; and there are 111 British residents at present on the islands, and 31 who are absent just now; most of these who are absent being children at school in other lands. There are about 7 Scandinavians, 5 Dutch, 3 Portuguese, 2 Americans and 1 Spanish. Besides those residing on the islands, there are on board the schooner "Friendship" 6 British, on board the "Croydon" 12 British, and on board H. M. S. "Dart" 59 British. Sir John Thurston has not made special inquiries, but, so far as he can gather, the European or white population of the New Hebrides is approximately as follows:—British—men, 57; women, 20; children, 28. French—men, 56; women 6; children, 6. Other nationalities, 9. This return includes missionaries of all nationalities and their families. No information as to the comparative areas of land claimed by foreigners resident in the group is forthcoming.

Lord Charles Scott, in his letter to the Premier, draws attention to "the fact that from May to November there are two of H. M. ships constantly cruising round the islands, visiting missionary and trading stations. Last year and this year a surveying ship has also been at work examining and charting the New Hebrides. The French have only one man-of-war cruising among the islands." His Excellency intimates his willingness to adopt Mr. Munro's suggestion that the officers of the ships visiting the New Hebrides should report upon the progress, condition, and prospects of settlement.

The names of the Missionaries, as marked by Mr. Atkinson on the chart, are: Mr. Laurie, Dr. Gunn, Mr. Grey, Mr. Robertson, Mr. Mackenzie, Mr. Macdonald, Mr. Nicholson, Mr. Fraser, Mr. Small, Mr. Annand, Mr. A. H. Macdonald. It will be seen that the Australian authorities take a deep interest in the New Hebrides,—their settlement and progress. Indeed some of the leading men in Victoria and New South Wales are banded in a Syndicate or Company for the cultivation of land in these islands, and they lately employed a Ceylon planter on a visit to Australia, Mr. C. P. Atkinson, brother-in-law of Captain Bayley to visit and report on the islands and their resources. We have arranged with Mr. Atkinson for the publication of his journal and report, assured that the contents will be interesting to our readers, although we may say that we do not think the New Hebrides are likely for a long time to come to compete with Ceylon in the production of tea and cacao, whatever may be the case in regard to the produce of the coconut palm. Special interest was added to Mr. Atkinson's visit by the fact that Professor Drummond was one of his fellow-travellers and had a very narrow escape from destruction when near the crater of one of the greatest active volcanoes in the world, which is at work on an island of the group. A large mass of red hot stone, ejected from the crater, fell on the spot where the great theological writer had been sitting just previously, and at which—(oh "lame and impotent conclusion") the Professor coolly lit his cigar. Mr. Atkinson's descriptions of the natives, savages and Christian converts, their manners and habits; of scenery, soil and productions, and of his intercourse with the missionaries, are graphic and interesting. He has a high opinion of the capabilities of the soil. Of the resources of the French colony of New Caledonia he writes in sanguine terms. There coffee is grown to a

considerable extent, and as it is entirely unaffected by disease; he advised planters in the New Hebrides to obtain seed thereon and to destroy some which they had obtained from Ceylon.

At present French and British influence are about on a par in the interesting group of Pacific islands known as the New Hebrides; but with equal advantages extended to each and protection as well as punishment extended to British settlers by their own Government, we expect that in the future the British will go ahead in numbers, wealth and influence until the islands become what their prototypes are—British possessions. That the people, the larger portion of whom are Christians, the converts of British Missionaries, earnestly desire annexation, and the rule and protection of the British, there can be no doubt. In any case, we may rely on it that Britain, looking at the strong feeling which exists amongst the British Colonists of Australia, is not likely to allow the French to possess the New Hebrides as well as New Caledonia in the West Pacific, so adding another to the alienated natural heritages of the future great Australian people, which they will demand back from foreign possessors, and which will probably be quietly yielded up, backed as the demand will be by one of the most powerful natives of the world: the Imperial or Republican navy of Australasia!

CELLULOID.

Celluloid, the composition of which was long kept secret, has for some years been largely employed for imitating articles made of horn, shell, ivory, and even marble. It has the immense advantage that it can be welded, melted, moulded, and shaped without difficulty, and it is, for this reason, now largely employed for the manufacture of walking-stick handles, umbrella handles, piano keys, &c.

The so-called American linen is only a layer of celluloid on a thin strip of cardboard or canvas. It has also been used for making rulers, set squares, and other similar instruments of precision, for it has been shown that the expansion of this substance is much more regular and uniform than that of wood, and that errors previously unavoidable, can be eliminated by its use.

This industrial product, now indispensable for a number of articles of every day use, is simply made up of nitrocellulose, camphor, and water. It was invented, in 1869, by two Americans, the brothers Hyatt, who soon endeavoured to bring their invention into general use by establishing works in the State of New Jersey, in a small locality known as New Arch, which owes its increase and prosperity to this industry.

In 1876 the brothers Hyatt introduced their industry into France, and established a similar manufactory at Stains, near St. Denis. France now has two large works where celluloid is made, together with a number of others of less importance, and the product turned out by these is considered the best in the market. Germany also possesses two large factories, the chief of which is that of Magnus, at Berlin, while the largest in the world is at London.

Mr. De La Royné describes the composition, manufacture, and properties of celluloid in the following manner, in the *Revue de Chemie Industrielle*:—

"Celluloid is not obtained by a single operation. A very thick collodion is first made, in which the ether is replaced by camphor, and which, therefore, contains proxylone or nitrocellulose, camphor, and alcohol, sometimes, and this is the method adopted in Germany; ether is also added. This collodion is brought to the consistency of a paste, slightly heated and rolled; the heat, which is gradually increased, removes the volatile solvents, and the proxylone and camphor combine in a more intimate manner to produce a horny transparent substance."—*Invention*,

THE FUTURE OF THE PETROLEUM TRADE.

The changes and developments in the petroleum trade during the last two years have been numerous. What the immediate future will show it is impossible at the present moment to predict; but it is evident that many surprises are in store for the trade. All who have studied the trade know that the present system of the distribution of petroleum is to a large extent artificial, and will require very considerable modification. The supply of petroleum for the entire world comes from Russia and the Eastern States of America. Batoum in the east and Philadelphia in the west are the two great distributing centres, and for the present the consumer in China or India must draw his supplies of illuminating oil from either of these two places. In a few years it is not improbable that we shall see a rival of Philadelphia established at Vancouver, tapping the practically unworked oil-fields of North-West Canada. From this part all Eastern Asia will be supplied. Another rival will be at Callao, in South America, from where the equally enormous supplies of oil around Lima will be exported to Australia and New Zealand. The two latter countries have oil deposits, but so far as can be ascertained at present neither is likely to supply all that will be required for their own consumption. Philadelphia will supply its home market, and will compete with Batoum from the trade of Europe. Batoum will be the natural distributing centre for Northern and Western Asia and East Africa. The oil industry is as yet in its infancy, and great is the future of the trade. When those who handle petroleum in this country have adapted themselves to the changing conditions of the trade, and have realized the great possibilities of this enormous industry, there will in the future be more made out of the trade than has been made in the past.—*British Mercantile Gazette*.

WHITE SAND PETROLEUM IN CANADA.

Oil was found last week for the first time in a white sand within the Dominion. The new discovery, which is attracting considerable attention, was discovered by the Provincial Natural Gas and Fuel Company, in one of its experimental wells near this place, which was being drilled ostensibly for gas. The well is not a gusher of the McDonald field class, but the sensation which it creates in the scientific mind is even more profound than the discovery of a gusher in the McDonald field, where such are to be expected. The oil is dark green in color, 45 gravity and possesses all the characteristic features of Pennsylvania oil. It is the first and only oil found in Canada which is free from the peculiar taint and malodore of oil produced from limestone rocks. This oil is found in the Medina at a depth of 750 feet; it is the first time in the history of the business in which the occurrence of oil in this horizon has been noticed by drillers or geologists; on the top, and for a considerable distance through it, the rock is a reddish hue, changing to grey toward the bottom; the oil was found in the grey sand. It marks a new era in oil development, which is of interest mainly in the Dominion, since this rock lies on or very near the surface, at the border line between Canada and the United States. The stratigraphical position of the Medina rock is very imperfectly understood by oil men on both sides of the line; on this, because in the oil fields proper, the wells start, as it were, in the shales underlying the Medina rock; on the other, the

established oil bearing rocks overlie the Medina. This discovery is of the greatest importance to Canada. The Lima equivalent, which is produced at Petrolea, commands \$1.35 a barrel at the wells. The same oil in the States is freely offered at 80c. Pennsylvania oil, which is in universal demand here, is subject to a duty of between 7c and 8c a gallon. This oil, which is equal to the best Pennsylvania product, will command from \$2.00 to \$2.50 a barrel at the wells. The credit for this discovery is due to the intelligent effort of Supt. E. Coste, of the Provincial Natural Gas Company. Mr. Coste is a graduate of the School of Mines and Mining of Paris, a member of the Dominion Geological Staff and one of the brightest and most enterprising geologists of Canada. He located the famous gas fields in this district, and pronounced upon the value of the territory before a well had been drilled. He said oil would likewise be found on one flank or the other of the gas field, basing his statement on geological interference. This well was located by him to test the accuracy of his theory, but no one had faith in it but the professor, and his confidence never wavered. Some 20 wells have been drilled in this district through, and beyond the Medina rock without finding oil in this horizon. The gas found in merchantable quantities, here comes from the Trenton rock, 1,700 feet below the Medina.

The oil well is located at a considerable distance to one side of the gas wells, and Dr. Coste ventures the prediction that an oil field of considerable area will be found in the vicinity. The first well has every outward indication of bringing a 25 bbl producer.—*Oil, Paint and Drug Reporter*.

THE CEYLON TEA PLANTATIONS CO., LTD., AND PERAK.—As the directors of the Ceylon Tea Plantation Co., Ltd., have resolved not to extend the field for their operations beyond this island, the question now is, what will be done with the 1,000 acres of land in Perak chosen by Mr. Talbot on behalf of the Company?

CINNAMON AS SNOFF FOR INFLUENZA.—Many preventives for the scourge have been suggested, but the simplest appears to be that adopted at the University of Durham. This consists of powdered cinnamon, which has been dispensed to the students in small boxes. It is taken in the form of snuff, two pinches per diem being the regulation allowance.—*Chemist and Druggist*.

A GIANTIC CORNISH CAMELLIA TREE.—Probably there is no exotic tree or shrub in West Cornwall with a more interesting pedigree than the camellia at Penalvern, Penzance; and, like so many other things with a glorious past, its future is an unknown quantity, except in the rapidity of its decay. It is but a wreck of its former self, and the mere imitation of the blizzard of last March will completely settle it. Half a century ago there were scarcely any camellia trees in West Cornwall, and for a very long period, up to last year, the one in question maintained its reputation as being the largest in the county. When in full bloom its magnificence could not have been exceeded by any single specimen in its native country, Japan. It reached an altitude of nearly twenty feet, and possessed a circumference of nearly three times its height. It was, at its prime, so densely covered with flowers that to photograph it was impossible. The young tree was brought about half a century ago by the late Mr. T. S. Bolitho from the gardens of his father-in-law, North Cornwall, and the vigour with which it grew and thrived in the genial locality of Penzance was little short of marvellous.—*Western Morning News*.

FROM THE METROPOLIS.
CEYLON TEA PRODUCTION AND
CONSUMPTION.

Feb. 6th.

That the total exports of Ceylon tea for 1891 should exceed 68 in place of 65 millions lb. of tea makes an important difference in the calculation I sent you for the current year. It is gratifying, of course, to see that the estimate I ventured to frame early last year has been so exactly realized, and adding an increase of 10 millions to 68 (in place of to 65) gives us a figure 78 millions, not for off the 80 million lb. at which we have put the total exports for 1892. "Oh! but"—say friends in tea on this side,—“you forget what an exceptionally wet forcing season 1891 presented!” “Not at all” we may reply, seeing that we allow a margin of 10 to 12 million lb. for that circumstance and other exceptional causes. It is a fact quite as likely that the total shipments should exceed, as fall short of, 80 millions lb. Nor can I see why this should frighten, or adversely affect, the home prospects of Ceylon tea. For surely the first effect should be to check speculation or investments in China teas during the approaching season more particularly in view of the heavy losses sustained (£500,000 estimated) last year, in which Eastern Banks as well as the dealers are supposed to share. From this point of view, indeed, one might expect high estimates for Ceylon shipments in 1892 and 1893 to act as a strong deterrent on the China tea trade; and more especially with the United Kingdom. Not only so, but also as a deterrent on further planting of tea in India, the Straits, Borneo, Africa or South America; for “tea” is given as a product suited to them all. The sooner it is widely known therefore that Ceylon is bound to increase her exports, year by year, for a good many years to come the better, I and a good many more friends of the colony at this end think. Among them, of course, is the veteran Mr. J. H. Roberts of Messrs. S. Rucker & Co., who first and so cheerfully and frankly urged Ceylon planters to hurry on with their planting, crops and exports, until 80 to 100 millions lb. of shipments to London were attained. I asked Mr. Roberts the other day, during a hurried call, “what he thought now of our giving London about 80 millions this year?” “Delighted to hear it” was his pleasant response, and I have to see him again and our old planting friend, Mr. J. Hamilton, to go over the prospects of Ceylon and its products with them. Of course even if 80 millions lb. are shipped from Colombo and Galle during 1892, not all will come to London—perhaps less than 74 millions will be so directed, more especially if the rumour of a differential duty to be imposed in the United States prove correct, so necessitating direct shipments. Seeing how well 63½ million lb. of Ceylon tea have been disposed of in the past twelvemonths, we need scarcely be frightened about 10 to 12 million lb. more going into consumption during 1892. Nor, if a check be given to China exports, should the average prices be lower, more particularly if due care be taken about “plucking” and “preparation” in Ceylon. Of course there is some reason for the query of our good friends in Rood Lane and other of the “Lanes” as to how the trade is to meet such large increases in production; but they are very ready to admit that for good tea, pure Ceylon, there will be a profitable market. So let all concerned beware of doing anything in 1892 to imperil and lower the good name of “Ceylon.” [Complaints have not yet quite died out, about the poor qualities being sent over in some cases,

although I hear no more of absolute “trash”—nor I trust shall this term be ever fairly applied to any Ceylon export again. If it is, an Inquisitorial Board would certainly be formed to find out all about it and give a word of warning, or something more, to the shipper.] I was sorry to miss another leading broker, Mr. Geo. White, whose firm have also taken such an intelligent interest in Ceylon tea, more especially in classifying our districts according to altitude. Mr. White has already started on a trip out to Ceylon where, I feel sure, he will meet with a hearty reception and enjoy his visit to the tea districts.

ANOTHER BIG CEYLON COMPANY.

Calling at the headquarters of the Ceylon and Oriental Investment Corporation, I had the good fortune to meet Mr. Huntly Thring, the Managing Director, Mr. H. A. Hancock of the well-known tea house, closely identified with this and the Lauderdale Company, and the Secretary, Mr. Chapman. [A caller soon after was Mr. Prior Palmer, who is about to return to Ceylon, and from whom I was glad to learn better news of Mr. Turpin, who is also likely to return ere long]. The taking over of the “Baring” estates in Ceylon to a value of perhaps £120,000, has added to the importance of the Investment Corporation, and it was very satisfactory to learn that they have so influential a Chairman as Mr. Hurg C. Smith, so good a Board and strong support. It is probable that the Company will be reconstituted on such a basis as may permit of their shares being quoted on the Stock Exchange—a great advantage. Meantime, the Ceylon tea planter, if he has had moderate prices of late, has been favoured with exceptionally low exchange; and we may well hope that the Americans may not succeed in inflating silver during the year at any rate, unless the “averages” for tea rise instead of fall.

Calling last evening, in Philpot Lane, to say farewell to Mr. Porter (who has started today via Folkestone for Marseilles and Ceylon, having Dr. Stevenson of the China Inland Mission as his travelling companion),—I was fortunate enough to find the Board of the Scottish Ceylon Tea Company sitting, and to meet such old friends as Messrs. H. L. and R. W. Forbes, both in good health and as usual cheery and confident about the future of Ceylon and its planting enterprise. Mr. H. L. Forbes had just recovered from an attack of influenza which he described as by no means a pleasant companion. It was interesting to learn that Major (and Mrs.) Forbes at 78 years of age, is still hale and hearty. Mr. Porter produced the latest circular arising out of Sir Andrew Clark's unfortunate speech, which runs as follows:—

In
LEAD PACKETS
½ lb. ... ¼ lb. ... 1 lb.
At 2s and 2s 6d per lb.
FINE CHINA TEA
Flavoured with Darjeeling Pekoe.

THE DOCTOR'S TEA

Recommended by leading men of the medical profession.
This Tea is the young spring leaf of the China Tea Plant and possesses less tannic acid than Indian Tea which is the cause of so much Indigestion and Nervous Debility. See Sir Andrew Clark's address to the medical men of London, Oct. 13th, 1891.

USE FINE BLACK CHINA TEA.

One gentleman present was able to recall a visit of Sir Andrew Clark some years ago to his home when he had a cup of Ceylon tea and the worthy doctor then pronounced it the finest tea he had ever tasted. From the letter of another Ceylon proprietor, received the other day, I quote as follows:—

“Sir A. Clark was supposed to recommend Ceylon tea, properly made, at one time. I take it that his real grievance now is with the fashionable ladies, who, while pretending to be so sympathetic and kind, grudge the trouble of making a little fresh tea for

a visitor. When tea cost double what it does now, people took more care in the making than they do at present.

As regards China tea, the following paragraph from the *Pall Mall* deserves worth giving:—

Here is an extract from the *Foochow Echo* which throws an interesting light on the two staple products of China:—

Two tea-growers are, we understand, planting poppies in the place of tea in the lower ranges of their tea plantations. If they meet with success, others will follow their example and give up tea altogether.

For this China has only herself to thank. By heavy export duty and local taxes and "squeezes" innumerable, she has done her very best to kill the trade which for so long gave her a proud pre-eminence among the countries of the world. That the poppy should take the place of the tea-plant is, however, a form of retributive vengeance from which China might well pray to be delivered.

The same journal's commercial correspondent sums up last month's trade in tea as follows:—

THE TEA TRADE DURING JANUARY.

Throughout the past month there was a strong and steady demand for all Indian teas with good liquors, but the poorer sorts, which were still too numerous, were not wanted unless at lower prices. At the close of the month, when offerings were smaller, the market hardened, and prices at date are much on a par with those ruling at end of December, except for teas with outstanding liquore, which are very scarce and decidedly higher. The average of public sale prices for the month was fully 8½d. per lb. against 11½d. per lb. for the corresponding month last year. The imports were 13,634,000 lb., and the deliveries 9,968,000 lb., leaving in stock on 31st January 49,162,000 lb. A satisfactory feature is the development of the export trade. The demand was strong during the month for all good Ceylon teas, and prices for such show an advance. On the other hand common leaf grades were depressed, and could be brought at very low quotations. The average of public sale prices was 9½d. per lb. against 11½d. per lb. for the corresponding month last year. The imports were 5,070,000 lb., and the deliveries 4,729,000 lb., leaving in stock on the 31st of January 15,780,000 lb. Of Java teas only insignificant offerings were made and very low prices realized. China teas remained steady during the month, at about previous quotations. The stock of China at the end of the month was 35,204,000 lb.

To show the interest Ceylon men and all connected with them maintain in the island's staple product, the experience related to me by a planting paterfamilias seems worth repeating. The family were out at "tea," including a little boy of eight, who on returning home criticized "the cup that cheers" as being very poor—"I suppose it was some of that China rubbish!" So much for "young Ceylon."

Good news has been received in London of the success of the "Down-Draft Sirocco" on Tillyrie estate, where satisfactory drying of teas has been done up to a weight much above the guarantee per hour.

"QUININE."

It is not made clear in this paper why quinine should not answer as well as "Saloin"—I suppose because influenza is regarded as allied more to rheumatism, a disease from exposure to damp rather than to malarious fever. That, however, cannot be true in all cases; and yet I learned as a fact in the editorial office of *Chemist and Druggist* the other day, that injury to quinine consumption (that is to cinchona planters) had been done through the persistent preaching and use of quinine in this influenza season, for many who had thus been led to take it suffered so much from headache and nausea that they vowed they would never touch a grain of it again, in their lives! The speakers instanced experience in

their own office among the large staff of lady assistants, clerks, &c., as bearing out this and doctors were strong on the point of sulphate of quinine not at all suiting many constitutions. There is no doubt some truth in this, though I should be inclined to suppose the headaches arising from taking too much at a time; and on the evil of some of the substitutes for quinine, it is enough to see what Messrs. Böhringer say in their latest circular:—

Quinine has proved itself to be a particularly effective remedy against this dangerous malady, being free from any bad effects, which is not the case with any of the new lately introduced fever remedies, such as Antipyrin, Antifebrin & Phenacetin. Attention has been frequently called to this fact, especially by Prof. Nothnagel of Vienna, who warns emphatically against using those new remedies in all cases of Pneumonia, which is brought about in most influenza cases, because he found that they have a weakening effect on the heart and as the latter is always more or less affected by Pneumonia, a dangerous state of weakness might issue; for the same reason he is greatly opposed to dispensing these new remedies to patients with a weak heart, although not suffering from Pneumonia.

Another fact mentioned as one bearing on the slow increase in the consumption of quinine in England, is the steady amelioration of the health of the people in the Fen and other districts long notorious for malaria and ague. A wholesale dispenser with good means of knowing declares that the sale of drugs (no doubt including laudanum as well as quinine) in such districts has fallen off owing to sanitary improvement, better drainage, &c., of recent years. Meantime, so great is the demand for cheap quinine generally that Messrs. Böhringer at Mannheim have to work night and day to meet their orders, a great proportion, however, being for America and south-eastern Europe. My friends of the *Chemist and Druggist* however, consider that the British consumption has also increased and especially that there are very few country druggists who now sell quinine at the old rate of 1s a grain (£2 an ounce) even in prescriptions; that generally 6 grains for 1s is more like the charge in retail or prescriptions. "Rivers Hicks," I am pleased to learn, is once more to go ahead with the sale of his quinine pills, but at rather dearer rates I am told; on the other hand, an enterprising Glasgow house (Anderson & Co.) advertise "penny quinine pills" in tubes and should meet with a good demand if, as is said, the London "penny" pills are now charged twopenny! * Some such result has occurred

* PUBLIC SUPPLY OF QUININE.

TO THE EDITOR OF "THE STAR."

Sir,—It has been suggested that a cheap supply of quinine would be very beneficial to the poorer classes of the community in this time of influenza. This can easily be provided by the London District Boards or Vestries; or by section 77 of the Public Health (London) Act, 1891:—

"Any sanitary authority may, with the sanction of the Local Government Board, themselves provide, or contract with any person to provide, a temporary supply of medicine and medical assistance for the poorer inhabitants of their district."

In the country the sanitary authorities have a similar power under the Public Health Act, 1875, section 133. Such a supply would be an enormous boon to large numbers of families. Of course the recipients would not become paupers. In some cases, no doubt it would prevent people from becoming paupers. Will the London vestries, &c., apply at once to the Local Government Board for its immediate sanction? And will the London Liberal and Radical M.P.'s write to the Local Government Board and request it to notify to the sanitary authorities that the sanction will be given if needed?—Yours, &c.,

J. THEODORE DODD.

during the last few weeks in reference to Eucalyptus Oil—pronounced a sufficient preventive of influenza. The demand became so great that the six-penny bottles speedily became a shilling and the article even then sold seemed very weak! Now, no doubt, there will be a run on "Salicin"; but influenza itself is on the wane and there can be no doubt that a great many so-called cases are only ordinary winter colds, and that of the older people who suffer and so many of whom die, the larger proportion would have the same experience if influenza had never been heard of. Still, of course, there is a considerable number of cases of undoubted "influenza" in its own peculiar form.

THE EUCALYPTUS IN SICK-ROOMS.—At present, when everybody is sniffing eucalyptus oil to ward off the influenza, the following from *Cassell's Magazine* will be interesting:—"The custom of placing green boughs of the eucalyptus or blue gum tree in sick rooms is extending in Australia. It is stated that the volatile perfume has a favourable effect on consumptive patients, and is also able to promote sleep. Dr. Curgeven expresses his opinion that if placed under the sick-bed in cases of scarlet fever the boughs will disinfect it and every article in the room."

THE TALGASWELA TEA COMPANY.

The annual general meeting of the Talgaswela Tea Company, Ltd., was held this afternoon in the offices of the Secretaries, Messrs. Baker & Hall, 17 Chatham Street. On the motion of Mr. T. W. Hall seconded by Mr. W. H. Davies Mr. H. Van Cuylenburg was called to the chair. The other gentlemen present were Messrs. E. Suhren, G. C. Walker and W. Baker. Mr. Van Cuylenburg in moving the adoption of the report which has already been published in our columns said he thought those present would agree with him that the report on the whole was satisfactory. The larger acreage of land opened to cultivation had necessitated a larger expenditure of money, and but for that fact there would have been a dividend declared for the year. However the property had been rendered more valuable and hope was held out of a dividend during the present year. Mr. Davies seconded and the report was adopted. On the motion of Mr. Walker, seconded by Mr. Davies, Messrs. T. W. Hall and H. Van Cuylenburg, the retiring directors were re-elected, and on the motion of Mr. Hall, seconded by Mr. Walker, Mr. John Guthrie was re-elected auditor. Mr. Hall afterwards said that he had been requested by a well-known planter to suggest that labour, Tamil or Sinhalese be induced to reside on the estate as the present mode of obtaining their labour was precarious, in view of future difficulties arising. He thought perhaps that in the absence of the Chairman this suggestion had better be made to the directors. The Chairman, he said, was better able to reply to that suggestion than any of those present because he was intimately connected with the actual working of the estate. In answer to Mr. Walker he said they had no lines. Their labourers came from the villages every day, and whilst being given to them every day they were paid at the end of the week. They had no resident labour whatever. Mr. Walker asked if the gentleman who made that suggestion was a low country planter, and Mr. Hall replied that he was a Badulla planter, well and favourably known, who had been down to the place and knew it. That gentleman also stated that cattle were cheap down at Talgaswela, buffaloes being to be had for their keep, and suggesting whether it would not be a good thing to have kraals made and the manure accumulated. That was a matter that was brought up by the same gentle-

man before and he (Mr. Hall) thought it was decided that the tea was very young and would not require manure for a long time. Whenever they did require it a large quantity could be procured at a small cost indeed. The meeting agreed that the matter should be brought before the directors. The proceedings then terminated with a vote of thanks to the chair.

Later an extraordinary general meeting was held to confirm the following special resolution passed at the meeting held for that purpose on Tuesday, 29th December last:—"That the sum of Rs30,000 be raised by an issue of 300 preference shares of Rs100 each, to carry a fixed interest of 7 per cent per annum, and that such shares be offered to the existing Shareholders of the Company *pro-rata*." In addition to those already mentioned Mr. George Armitage was present. Mr. Van Cuylenburg again presided and said that he saw by the Ordinance that unless a poll was demanded by five of the shareholders he would be entitled simply to put the resolution and declare it confirmed. Mr. Hall was understood to say that they must have a poll, but Mr. Van Cuylenburg said that was not necessary, and as he took it that there was no desire for a poll he declared the resolution duly confirmed. Some conversation took place as to the position of preference shareholders, Mr. Van Cuylenburg mentioned that some shareholders or directors wished to be satisfied on certain points, and the opinion of counsel had been obtained and was laid on table. The first question put was as to whether preference shareholders would be entitled to vote in common with ordinary shareholders. Well, the Ordinance made no exception, and there could be no question that every shareholder ordinary or preference was entitled to vote. The second point was as to whether in the event of the Company's going into liquidation the preference shareholders would be entitled to priority of payment. He did not think it was necessary to go into that question because by the terms of the resolution that had been passed it was clearly set forth that the preference shareholders should be entitled to 7 per cent of interest which must be paid preferentially. Replying to Mr. Suhren he said that in the articles of association there were two questions as regarded preference shares, the first being in reference to dividends, and the second, distribution of assets. Well, if they considered it necessary to go into that question it would be necessary before issuing the shares to pass a general meeting declaring that the preference shareholders should have a preferential right in the distribution of assets. Of course that raised the question but he understood that the preference shareholders would be satisfied with their 7 per cent of dividend. This however did not strictly form part of their business that day. Mr. Walker asked if they could not pass the resolution with regard to assets after the issue of the shares, and Mr. Van Cuylenburg said it was clearly provided that that should be done before the issue. The Chairman suggested that it was a matter for their lawyers to decide, namely, what should be the conditions upon which these shares should be issued. Mr. Armitage said it was not simply a question of legal opinion but what the shareholders generally thought. Mr. Baker said they had good enough security, and Mr. Armitage re-echoed that opinion, adding, if there was going to be a distribution of assets he did not see why the preference shareholders should come in before the others. If it were decided six years hence to wind up the Company the preference shareholders would have had 7 per cent all these years and the others only perhaps

2 or 3 per cent. Mr. Suhren remarked however that there would be a difference if the Company did well; the others perhaps might have 20 per cent. Mr. Armitage said that these shareholders had got very good security with the seven per cent. The Chairman supposed these shares would really be taken up entirely by the shareholders. There was also some talk about what would be the position of parties in the event of the Co.'s property being mortgaged, but Mr. Hall remarked that as there was no earthly chance of a mortgage being effected it was unnecessary to discuss this. The proceedings terminated with a vote of thanks to the chair.

NOTES ON PRODUCE AND FINANCE.

A WONDERFUL SCHEME.—The following advertisement which appears in the *Grocer*, may be taken as a sequel to the letter of "A Secretary" on the subject of tea retailing and tea growing, to which we have referred in our two last issues:—"Important to grocers. Tea plantations. A scheme will be submitted, by which a leading grocer can obtain in his district proprietary rights of certain tea plantations in Ceylon and India, and, by thus becoming his own planter, use it as a powerful advertisement to further his interests. The produce of the plantations will be offered direct to him without the intervention of any unnecessary charges—equal to a saving of 10 to 20 per cent on prices usually charged by wholesale London dealers. Reasons why a grocer should at once acquire the rights in his district: 1. Because he will buy his loose tea at least 10 per cent cheaper than from any other source. 2. Because the fact of being his own planter is the strongest position he can occupy for advertising and trading purposes. 3. Because only one bona fide grocer will be accepted in a district. 4. Because he will then become the only grocer in his district who ships tea direct from his own plantations. 5. Because he can acquire proprietary rights by giving a contract for tea in lieu of paying cash. 6. Because the plantations will be managed by one of the largest and most experienced tea planting firms, who guarantee a minimum dividend of 5 per cent, and to repurchase his share when he wishes to realise. 7. Because, as a proprietor, he is not in any way bound to purchase his tea from the plantations, and thus reserves a free hand. 8. Because, if he doesn't join at once someone else in his district will step in before him. Full particulars on application to the Secretary, Tea Plantations Grocer Office, Eastcheap Buildings, E. C."

TEA GROWING AND TEA RETAILING.—In support of the view we have taken that tea planting and tea retailing do not necessarily work well in combination, we have received several communications. There are also two letters in the *Grocer* supporting our side of the argument. In one of these Mr. Llewellyn-Ighes, a planter who has tried tea growing and tea retailing in combination, in the course of a long letter, says:—"Yes, I am the retailer who has tried it; and if 'The Secretary' desires me, through your columns, to enlighten a guileless public on the subject, I shall be pleased to do so. N. B.—I hope, however, for his own sake, that he alone has taken up all the shares in the 'Tea Plantation Company now in course of formation,' before this appears in print; but especially so should he require any further information. With regard to Mr. Lipton's opinion, as quoted by your correspondent, it must be taken *cum grano salis*. I congratulate him on getting a cheap advertisement. N. B.—My retail friends must not be guided by it. It is misleading

—nay, I will venture to assert it is positively dangerous. Mr. Lipton forgets, or perhaps does not know, that teas of every grade and description often get into the hands of the retailer for less money than they cost the producer. It is nevertheless a fact."

FURTHER TESTIMONY.—"Another phase," says another correspondent, "of the question of tea-growing, which perhaps furnishes the most powerful reason why retailers should consider well before entering on such a course, is the fact that, buying on the open market in combination, dealers will invariably be able to select more suitable goods from an assortment furnished by between thirteen and fourteen hundred gardens, covering an area at the present time in India and Ceylon of upwards of half-a-million acres." Mr. Valentine, of Belfast also writes:—"I have read with much interest the correspondence in your columns relative to the above subject, being a tea planter of some years experience, and one of the largest retailers in Ireland. I know many tea-growers (retailers), but I never met any retailer tea offered by a 'grower' that I would not undertake to retail (similar tea in every respect) in my depôts at pence per pound under the price they were offering it at." It appears clear from this evidence that our contention was not far wrong—viz., that a retailer who offers tea from a garden or gardens in which he is interested is not, therefore, and by reason of this, in a better position to supply tea retail than a purchaser of the product in the Lane. Beyond this point there is no occasion to pursue the matter.

TEA FIGURES.—The deliveries in London during January showed an important decrease of 937,225 lb. compared with those in 1891, the total being 19,894,076 lb., against 20,831,301 lb.; those of China were only 5,072,343 lb., as compared with 6,435,795 lb., or a decrease of 1,363,450 lb.; Java showed a decrease of 134,000 lb., and even Indian fell off to an extent of 603,147 lb. On the other hand, Ceylon shows the further large increase of 1,163,204 lb. The landings in January were 966,400 lb. in excess of the previous year, although those of China were only 4,136,753 lb., against 5,666,318 lb.; Java and Japan, 130,020 lb., against 194,520 lb.; Indian being 376,000 lb. in excess, whilst Ceylon showed the large extension of 2,184,400 lb. The landings of China Congou were 2,057,049 lb., against 3,568,017 lb., leaving a stock of 22,328,256 lb., against 36,294,093 lb. The landings of Green last month were 440,228 lb., against 1,145,852 lb., the deliveries 458,347 lb., against 517,620 lb., and the stock is now 3,439,880 lb., against 2,801,320 lb. in 1891. The total stock at the end of January was 100,602,757 lb., against 91,678,180 lb., showing the larger relative surplus of nearly 9,000,000 lb., Indian and Ceylon being 18,000,000 lb. in excess, and China 9,000,000 lb. less.

DARJEELING TEA.—In their monthly Darjeeling tea report for January, Messrs. Lloyd and Carter say:—"During the past month sales have been very heavy, and as some Darjeeling have shown improved quality, they have been freely taken at advancing rates. Anything choice has been strongly competed for at long prices, and it is satisfactory to find the country dealers pushing the trade in fine teas. The deliveries and stocks are again disappointing, considering the low quotations of all the common grades. China teas are dull, but teas for price remain firm, though fine sorts are unduly depressed. Ceylons are selling well at firm rates.

JUST REGISTERED.—Under the title of the Anglo-Assam Co-operative Tea Company, Limited, a company has just been registered, with a capital of £8,000 in £1 shares. Object, to acquire the undertaking of the Lung Soong Tea Estate, now

being carried on in Assam, in accordance with an agreement, made Jan. 27th between C. L. P. White, on the one part, and C. J. Roberts, on behalf of this company, on the other part, and generally to carry on business as tea planters, tea merchants and exporters in all its branches, both wholesale and retail, in India, China, Ceylon, or elsewhere. There shall not be less than three, nor more than seven directors; the first to be appointed by the signatories to the memorandum of association. Qualification, £50. Remuneration £200 and 10 per cent on all sums paid as dividend in each year—the same to be divisible.

LAST WEEK'S SALES.—The India tea market (says the *Produce Markets' Review*) has shown greater steadiness, due apparently to a smaller supply dealt with the quantity being 31,000 packages, against 36,300 in the preceding week, and common grades which largely predominated, bought fully late rates, closing with a firmer tendency excepting only for teas of very poor quality. The good medium descriptions have been well competed for, and values generally are firmer, and it is not improbable that these grades have touched the lowest prices. At any rate, the supply is not likely to exceed requirements, as, at the present comparatively low prices, these kinds are entering freely into consumption, and a hardening market may therefore be expected later on, especially as the quantity to be brought forward will be then smaller than hitherto. The finest sorts have again attracted considerable attention and brought higher prices, while tea of exceptional quality sold at extreme rates. It was hardly to be expected that Ceylon teas could remain very long at the present extremely low level without attracting considerable attention, and the demand has improved during the past week, and has resulted in a much better business than has been done since November. The effect upon prices, has however, been scarcely perceptible, and Ceylon teas still continue to present better value than any other growths, although for common grades worth from 5d to 5½d prices are firmer. There is, however, little alteration in the value of the finer Pekoes and Broken teas, but the quality has shown a general improvement. Java teas are much neglected, the extraordinary cheapness of Indian and Ceylon common grades rendering their use at present unnecessary. The arrivals for the week are:—The "Paklin," from Yokohama, Shanghai, Foochow, Hong Kong and Colombo; "Rosetta" from Shanghai and Hong Kong; "Flint-shiro" from Kong Kong; "Kaiser-i-Hind" "Clan McArthur," "Karamania" and "Goorkha" from Calcutta and Colombo; "Ormuz" and "Port Caroline" from Colombo.—*H. and C. Mail.*

SHEVAROY PLANTING NOTES.

YERCAUD, Feb. 15.—The coffee crop for the season now terminating has been almost all picked. Only a few of the estates of higher elevation have still to be stripped and gleaned, so that what promised to be an extended season will, after all, close about the usual time for these Hills. Crops, I am sorry to say, have not generally come up to estimates, the reason being that the alternate rain and sun-shine during both of the last monsoons, brought out a succession of blossoms, several of which failed *in toto*; so that under the circumstances it was very difficult to make reliable estimates. A further and somewhat novel reason, too, is that green birds of a particularly voracious variety, with a distinct and remarkable penchant for coffee seeds—not the pulp—have carried away untold quantities. These birds we have seen before about crop time, but this year they have visited

us in great numbers, abandoning their usual haunts on the lower slopes in consequence of the scarcity of their usual food there, viz., jungle berries of all sorts. The rainfall last year was below our usual quantity, Yercaud had 40½ inches, the other two Districts about 5 inches more—the average is 60 to 65 inches. This shortfall has not affected the coffee, but I fear there will be trouble about water; wells are sure to give out before the heavy rains can be expected, and streams are already running low. For the first time for many years the lake has not supplied the large waterfall stream with water. As with this so it is with other sources of supply. The tanks in the low country have not been properly filled, and I fear there will be a greater scarcity of water in and around Salem. Coffee, as I remarked, is looking well, indeed it is in much better heart than for years past, so that planters are looking for better crops. It is about time, for Government refuses us any remission, though it grants it to the ryot, and I fancy the ryot has been better off than many planters of small holdings. Prices have again reached last year's figure of R15 per bushel of dry parchment delivered on the estate. It has perhaps been somewhat of a surprise to some of your readers that Shevaroy coffee should fetch extreme prices out here, but the fact is the quality of our staple is so good and the outturn so heavy, that it is found to be a desirable sort to mix with inferior sorts, a custom I am told is regularly followed by Chetties. Planters up here evidently consider it better to sell on the spot and realise at once at the good rates prevailing than to ship for the home market and keep up the name gained in years gone by. Generally the estates up here are considered small as compared with those in Coorg, Wynad and the Nilgiris and crops are counted by tons instead of tens of tons so that after all it is perhaps better to sell in the country. Several planters are, I hear, opening out fresh land in spite of the disheartening prediction of some that the Shevaroy as a planting centre is played out! Coorg seems to be the El Dorado sought by these prophets, and I do not wonder, if, as told by your correspondent from that part, estimates were so far more than realised. One of the planters from here sought pastures new in Perak, but found the difficulty of obtaining labour and the unsatisfactory climate a bar to his aspirations of obtaining a competency in a few years. Government has once again refused our request to invest the Deputy Tahsildar with the powers of a District Munsiff; the High Court has, however, made a fresh arrangement that the District Munsiff from Salem is to hold Court in Yercaud regularly once in three months, and with this we must perforce remain content. Clouds have been gathering for the past few days, and today we have had a small shower. It is sincerely to be hoped the rain will not come down till, say, 15th March. These February rains are most disastrous. Last year it rained in the same month, and every planter was astonished at the wretched outturn of his first pickings.—*M. Mail.*

THE COMPARATIVE VALUE OF VARIOUS FUELS.

To enter into a full discussion of the scientific methods by which the relative heating values of the different materials used as fuel are ascertained, would be tedious, and at the same time would possess little practical value to the majority of the readers of the *Gardeners' Chronicle*; but the following general statement of the principles upon which such values depend, may be of interest to many whose business demands considerable outlay in this direction.

It has been found, as a result of elaborate experiments that the heating power of any fuel, whether coal, coke, charcoal, wood, peat, or turf, is approximately proportionate to the percentage, by weight, of the carbon which it contains; hence, coke, consisting as it does, almost entirely of carbon, in a greater or lesser degree of purity takes the lead as a heat-producer. Anthracite a good sample of which contains 90 per cent or more of carbon, heads the list of coals. Its hardness and compactness, and the absence of flame-producing constituents render a strong draught and careful stoking essential for its economical combustion. Other hard Welsh or steam coals have from 75 to 90 per cent, the average being about 84 per cent; Newcastle coals average 82 per cent; Derbyshire, 80 per cent; Scotch, 78.5 per cent; and Lancashire, 78 per cent. Of course extreme variations, upwards and downwards, are found in all the above districts. Again, the "heat-value" of any fuel is modified by the presence of (1) water, as such, or of (2) the uncombined hydrogen and oxygen in the proportion in which they unite to form water, i.e., eight parts by weight of oxygen to one part of hydrogen. The greater the amount of water, or of its constituent gasses, the smaller becomes the heating power of the fuel.

The reasons for this are not far to seek. The heat disengaged in combination (using the word in its ordinary sense), depends upon the chemical combination of the elements contained in the substance burnt with the oxygen of the air—the carbon with oxygen forming carbonic acid gas, the hydrogen with oxygen forming water. It is clear, then, that any elements existing in a fuel already in a state of combination, are, from a heat-producing point of view, so much waste material.

With regard to the presence of the hydrogen in an uncombined state, the case is somewhat different. Here the hydrogen combines with oxygen (present in the fuel itself, or in the air), the union being attended by the generation of a very large amount of heat, far greater than would be the result of the combustion of an equal weight of carbon. How then can the hydrogen be considered disadvantageous to a fuel? Simply because a more than compensating amount of heat is used up in raising the temperature of the water to the boiling-point, and in its conversion into steam. This will readily be understood, when it is remembered that as much heat is required to raise a pound of water from freezing-point to boiling-point as would raise a pound of iron to about 900° centigrade (a bright red heat), and that five and a half times as much heat would be needed to turn a pound of water at boiling-point into a pound of steam at the same temperature.

These deductions from theory are fully borne out by the results of practical experiments, it being found that the heating power of a fuel varies directly as the amount of carbon, and indirectly as the quantity of water and its elements, or incombustible ash, contained.

Here we are met by an apparent paradox, which has led to much misconception, and consequent error in practice, and which is therefore deserving of the attention of practical men.

It was first shown by Bunsen, that when steam is passed over red-hot carbon, it is decomposed; the glowing carbon uniting with the oxygen to form carbon monoxid and carbon dioxide, and the hydrogen passing off partly uncombined. The carbon monoxide and the hydrogen unite with oxygen (forming water and carbonic anhydride respectively), and the amount of heat thus generated is found to be greater than would be evolved in the ordinary combustion of the carbon without the intervention of the steam. This application of water-vapour must, however, be carried out with great care, for when present in excess, it decreases, rather than augments, the heat generated. The proper way to apply water for raising the temperature is to place it in an open pan beneath the firegrate, thus utilizing the heat which is radiated downwards from the fire for its vaporisation. Many have fallen into the error of wetting coal before placing on the fire, with the result that the amount of heat has been lessened rather than increased, as is evident from what was said above. It is

possible that coke, if fresh, may be advantageously damped in moderation, but it has the power of absorbing a large amount of moisture from the atmosphere without any sprinkling.

Too much emphasis cannot be laid upon the necessity for careful and intelligent stoking, no matter what the class of fuel employed. Careful trial should be made of various kinds used by any particular furnace, and the stoking should be carried out in such a manner as to ensure perfect and complete combustion. If anthracite or other hard coal be used, for instance, thin fires and a strong draught are essential. The importance of stoking was well seen in a case that came under the notice of the writer during the hard frosts of last winter. The furnaces of a market-nursery were stoked for some time by a gardener whose only idea seemed to be to pile on the coal. A man who had had some years experience, an engine-driver in a factory, was then put on stoking duty, with the result that, in much colder weather, the coal consumption was reduced considerably.

In conclusion, the main question as to which is the most economical fuel for glass-houses, is one that can only be determined by actual experiment with each system of heating, and by considering, independently and in conjunction, the heat-value of the available fuel, the cost of each, and the kind of boiler used.

The following table, taken from Scheerer's *Metal-lurgy*, may be useful, as indicating the relative heating effects of different fuels, although the figures must be taken with caution, as being the result of theoretical deductions rather than that of practical experiments with ordinary boilers.

Fuel.	Heating Power.
Good coke, with 10 per cent moisture and 5 per cent ash ..	2,350
Best coke, 5 per cent moisture and 3 per cent ash ..	2,400
Best coke, no moisture, and 3 per cent ash ..	2,450
Air-dried black wood charcoal, 12 per cent moisture..	2,450
Anthracite, 5 per cent moisture, 5 per cent ash..	2,350
Caking coal, 5 per cent moisture, 5 per cent ash..	2,300
Sinter coal, 5 per cent moisture, 5 per cent ash ..	2,250
Lignite, various ..	from 1,800 to 2,200
Turf peat (without moisture) ..	2,000
Turf peat, 30 per cent moisture ..	1,575
Air-dried wood, with 20 per cent moisture ..	1,575

C. W. H. G.

—*Gardeners' Chronicle*, January 30th.

THE YATADERIA TEA CO. OF CEYLON, LD.

The annual meeting of this Company was held at 13 Queen Street, Colombo, on the 26th Feby.

Mr. H. V. MAREFIELD was in the chair, and the following shareholders were present:—Messrs. J. H. Staley (Managing Director), C. M. Gwatkin, J. R. Fairweather, B. G. L. Bremner (Secretary), and by attorney, Mr. W. W. Church and Mr. D. Fairweather.

The SECRETARY read the notice convening the meeting. The minutes of the extraordinary meeting held on 31st July 1891 were duly confirmed.

The report of the directors which has already been published which was taken as read, was as follows:—

The Directors have the pleasure to submit the balance-sheet and profit and loss account for the year ending 31st December, 1891, duly audited.

The balance of profit (including Rs. 1,751-18 brought forward from last year, after writing off for deprecia-

tion of buildings and machinery as shown by the accounts) is R58,736.29. Of this sum R22,800 has been absorbed in paying an interim dividend at the rate of 12 per cent, and the Directors propose that a further dividend of 13 per cent, absorbing R24,700, be declared and made payable on the 27th February, and that the remainder of R11,236.29 be carried forward.

It will be seen that the property representing capital stands in the balance-sheet at the reduced sum of approximately, R331 per acre cultivated, in comparison with about R350 per acre in the previous year's accounts. The Directors hope to be able to show continued improvement in this manner from year to year, as new land is opened, and buildings and machinery are written down.

The additional withering house referred to in the last report has been completed, and another dryer erected. An additional large roller is in order. The Superintendent's permanent bungalow has yet to be built.

The total tea crop was 396,577 lb. or 96,577 lb. more than estimated in the last report the excess being mainly due to very favorable weather for leaf production. The plucking area was 521 acres, of which 41 acres were under leaf for a part of the year only.

The total quantity of tea for disposal was 399,568 lb., which included 3,004 lb. tea made from leaf purchased. The whole crop was disposed of in Ceylon. The cost of the tea delivered to buyers, including all charges and depreciation of buildings and machinery, was 23.27 cent per lb. (being about 7½ cent less than in 1890). The net value realized from sale was 37.47 cent per lb. (being about 3.2 cent less than for the previous crop). The quality during the later months of the season was much inferior to that of the earlier months. The market in the year was materially lower; particularly for teas of the class produced.

The Company's property, having been increased by the purchase of 69 acres, Crown land consisted at 31st December, 1891, of:—

		lb. per acre.
579 acres Tea— viz. :—	172 acres Tea planted in 1885; yield in 1891.	.950
	208 " " " 1887: " "	.821
	100 " " " 1888. " "	.491
	41 " " " 1889: " "	.323
	6 " " " 1890; (not in bearing.)	
	52 " " " 1891; (" ")	
	119 " " " to be planted 1892:	
255 " Forest, &c.		

953 acres
The Directors have undertaken 119 acres Tea extension for 1892, of which 29 acres were partly prepared in 1891.

The estimated Crop for 1892 is 440,000 lb.
Mr. H. V. Masfield retires from the Board by rotation, in terms of the articles of Association, and being eligible offers himself for re-election. The appointment of an Auditor for the current year will rest with the meeting.—By Order of the Directors, B. G. L. BREMNER, Secretary.

Colombo, 17th Feb. 1892.
Mr. MASEFIELD moved its adoption, explaining that by an error Mr. D. Fairweather's name had been entered as that of the Director retiring instead of his own.

The MANAGING DIRECTOR in seconding the motion offered the following remarks upon the accounts and business. He said that the report embodied the fullest information it was possible to give. It was subject for congratulation that, whilst making a substantial division of profits, the capital value in the balance sheet showed a reduction of nearly R20 per acre, the 588 acres planted standing at R194.66½, or about R331 per acre. The Directors had carefully considered whether a larger dividend might advisably be paid, the balance carried forward being sufficient to pay about 5 per cent; but considering that the margin of profit between cost of teas and sale prices was not so large in the second half of the year as in the first half-year, and that the market for lowcountry teas is at present depressed, further

that the new clearings required funds to be in hand,—it was determined to recommend a dividend of 25 per cent for the year, of which 12 per cent had been paid as an interim dividend. He had noticed that another public company carried forward or set aside as much as 15 per cent at the end of last year. The profit for the year was 30.95 per cent, besides which 6.80 per cent had been absorbed in writing off for depreciation of buildings and machinery. In the year the teas manufactured had improved in value, and the cost of production was lower by 7½ cents. The new withering house referred to last year was nearly completed for a sum within the estimated cost of R10,000. 52 acres had been added to the cultivation against 40 estimated, and extensions for 1892 had been begun. The shares had steadily improved in value during the year, several transactions having taken place at R200. There had been a slight increase in the number of shareholders.

The report was formally adopted. Mr. C. M. GWATKIN proposed that a dividend at the rate of 13 per cent (or R13 per share) be declared for the half-year ending 31st Dec., 1891, and that it be made payable on 27th inst. Mr. J. R. FAIRWEATHER having seconded, it was carried.

Mr. J. R. FAIRWEATHER proposed that Mr. H. V. Masfield be re-elected a director. Seconded by Mr. C. M. GWATKIN and carried.

Mr. C. M. GWATKIN proposed that Mr. J. Guthrie be re-elected auditors. Seconded Mr. J. R. FAIRWEATHER and carried.

A vote of thanks to the chair closed the proceedings.

TEA AND BUDDHISM IN JAPAN.—In a lecture on Japan recently delivered in Chicago Sir Edwin Arnold said:—

It is a curious thing that the architecture of their cities and the character of their houses and their furniture have all been really dictated to the nation by the teacup or teapot. A long time ago Buddhism and the tea pot came into Japan together. Buddhism was a rather corrupt form, derived as it was from China. But it brought into the nation what Buddhism always brings in an Asiatic people, softness and grace of manner, and easy pleasure in living, and an absolute resignation to that inevitable process of ceasing to live, which we call dying. The Japanese is less afraid to die, as I have seen in many hospitals, than anybody I know. That he owes to Buddhism. But he also owes to Buddhism the teapot and the teaplant. Ito Jassu said:—"Let me invent something that the poorest Japanese can enjoy as well as the noble. Let it be graceful and polite; let it be cheap." Then he said; "I have got it—the teapot." You never enter a house but the teapot is brought to you, and in drinking that tea you must observe certain ceremonies, which are very simple, but which elevate and refine the character of the people. They are so graceful that they even call the hot water with which they make the tea "the honourable hot water," while if it boils twice it is called "the mature hot water." Half of the grace of the language and wonderfully polite forms of the Japanese have really grown out of tea drinking. One special form of tea drinking is called Cha No Yu, which is more solemn than a choral service in a cathedral and to which you must be educated before you take part. This is not ordinary, and it is not an example. Then, in order to be always ready to make tea, in every room, in every house, in every town, in every province in Japan, there is that He Ba Che and the She Ba Che. They have no stoves and no fireplace, although the country in winter is bitterly cold, but always the fire-box—the he ha che, a little square or oblong box of copper in which purified charcoal is always burning,—
Japan Weekly Mail.

JAPAN TEA.—From the Paris edition of the *New York Herald* we quote on our last page an interesting account of Japan tea. We may add that the indigenous Assam tea tree attains in its native forests a height of 45 feet, and that we find it very difficult to believe that tea yields 2,500 lb per acre in Japan.

CINCHONA IN JAVA.—The report on the Java Government cinchona enterprize for the fourth quarter of 1891 states that during October and in the beginning of November the weather was continuously dry. In the first half of November rain set in heavily, but was intermitted in the middle of December by some ten days of dry weather. The long drought was not favorable for the young plants, and the plantations formed in March and April suffered much from want of rain, necessitating supplying on a large scale. For the older producing plantations however the continuous drought was very favorable. Although the growth in the plantations was small in the latter part of the severe east monsoon, shortly after the setting in of the rain they began to grow vigorously, as was indeed to be expected from the thorough working the soil that has been carried out during the past year. The experiment tried with the scraping of second and third stems of ledgerianas of bush growth far exceeded expectations. Not only did the scraped portions quickly recover from the operation and the plantations preserve their density, in consequence of which the caterpillar plague is as good as stopped, but the untouched main stems grew all the more vigorously on the setting in of the rain, so that the aim, the formation of single-stemmed trees, has been greatly furthered by this operation. The crop of 1891 comprises about 550,000 half kilograms of bark, of which by the end of the year 517,330 pounds had been sent to Tandjong Priok. Though the increase in production during the past year is of little moment, it is worthy of note, that by the application of the scraping method an outturn of ledgeriana of nearly 200,000 half kilos of slivers were obtained with a content representing nearly 10 per cent of quinine sulphate, and that, of the crop of druggists' barks, quills were almost entirely got. On 8th October, 12th November and 17th December sales of cinchona bark of the crop of 1890 were held in Amsterdam. The unit price for manufacturers' bark at these sales was 5½, 6 and 5½ cents respectively. The small supply of ledgeriana seed permitted of the sale of only a single sale of seed. For ledgeriana seed from original trees up to 13.60 per gram was paid. The net return of this sale was 1,472.75. By Government order No. 20 of 3rd Dec. 1891, authority was given for the laying out of three isolated plantations, each of two *bonus*, for the obtaining of seed. In one of these plantations only those ledgerianas richest in quinine will be planted, in the second hybrids of *O. ledgeriana* and *C. succirubra*, and in the third, ledgerianas and hybrids together in order to create new crossings. The grafts intended for the plantations, which are chosen with the greatest care, are already to some extent available in the nurseries at Tjinjroean, so that a commencement can be soon made with the laying out of these plantations. The total number of plants of all kinds in the Government plantations at the end of 1891 was 3,549,100. In the nurseries there were 842,000, viz.—362,000 ledgeriana (including 27,000 grafts), and 480,000 succirubra. In the open there were 2,707,100, viz.—2,034,000 ledgeriana (including 270,000 cuttings and grafts, and exclusive of the more or less 3,000 original ledgerianas), 2,200 calisaya and hasskarliana, 621,000 succirubra and caloptora, 47,900 officinalis, and 2,000 lancifolia.

NOTES FROM FOOCOO.—We hear that disappointed native tea men have now positively decided to carry over at least 15,000 chests of their first crop tea to next season, expecting to do better by holding. They know their own business best, but it appears to us that unless some wonderful change takes place in the foreign markets to which we ship they will be 'jumping from the frying pan into the fire.' Foochoo chaaszes are always ready to buy old seasons common teas when new are scarce and they want tea for price. By June next these over held teas should ripen into something near this commodity and if chaaszes are wanting tea for price they will buy them, but the holders must not think they can palm off stale bns at anything like the price of new ones, no matter how good they may have been.—*Echo*.

When a Scottish farmer proposed some fifty years ago to stimulate the growth of his crops by electricity there was a loud guffaw among the country folks at the idea of 'muckin' the lan' wi' thun'er.' But in half a century we have learned a good deal, and the results of the latest experiments seem to point to a time when a dynamo will be as much an agricultural implement as a reaping machine. Siemens found that fruit and flowers prospered amazingly under the electric light, and now we have the chemists employed at the Amherst Experimental Station in Massachusetts intimating that the plants subjected through their roots to the greatest electrical influence are hardier, healthier, larger and possessed of a better colour, and less affected than those grown under the ordinary conditions. Electrified seeds developed twice as rapidly as those not treated in this manner, so that there is now a hope that it may be possible to enable certain crops to reach the stage at which they are liable to insect attacks before the larvae are ready to prey upon them. Vines treated to electrical stimulation develop a large percentage of moisture and sugar, and less of the undesirable tartaric acid, than others left alone, and it has long been known that plants grown in metallic cages around which electric currents circulate assimilate nitrogen with much rapidity.—*Daily Graphic*.

Mr. J. E. Durne, the well-known botanist, writes from Saharunpore:—"The periodical flowering of certain kinds of bamboos is an event which attracts the attention of many people, in the same way as they are interested in total eclipses, the appearance of comets, and such like obvious phenomena. Those who are unable to regard the event from a scientific point of view are apt to hold superstitious opinions, especially the Indian cultivator, who, for instance, invariably looks on the periodical flowering of the 'Kattang bns' (*Bambusa arundinacea*) as directly connected with an approaching famine. This season should be recorded as a memorable one on account of the flowering of the sugarcane. I have not yet been able to ascertain to what extent this is taking place in other parts of India, but it is sufficient at present to notice the fact of its flowering freely in the district after an interval of about twenty years. The particular point to which I wish now to draw attention, is the possible opportunity of obtaining ripe seed. It has been supposed, and with reason, that crops like sugarcane, which have to be propagated year after year by cuttings, will after a time begin to deteriorate, either by reason of the want of fresh blood or—and perhaps in consequence of this—their liability to various diseases. Hence all who are interested in the future cultivation of sugarcane should at once endeavour to have as much seed collected as possible before it is all carried away by the wind."—*Indian Agriculturist*.

TEA VS. COFFEE.

(From the *Financial World*, Jan. 9th.)

The pleasant air of a family tea party which usually distinguishes the meetings of the Ceylon Tea Plantation Company was quite absent from the gathering at Winchester House on Wednesday. There were no ructions—the shareholders are far too decorous for that—but the proposition of the board to buy a coffee plantation in the Straits Settlements was as distasteful as strong Mocha would be to the drinker of tea who reckons coffee to be rather "eating." In fact, they would have none of it.

The first proposition of the business went smoothly enough. Mr. David Reid, the Chairman, said that the policy of the board had been directed to increasing the area of cultivation in high altitudes by acquiring estates of an exceptionally high quality. It had been arranged that they should never buy an estate whose average quality did not come up to the quality of the company's estates, so that it was by no means an easy matter to acquire an estate of this character without having to pay fancy prices. The directors, so far, had been successful in carrying out that policy, and the purchases which the board now asked them to sanction fulfilled those conditions. The highest price they had as yet paid for an acre of tea-planted land was for Yoxford, which was undoubtedly a very fine property, and well worth the £18,000 paid for it. It would, they believed, easily give 15 per cent. on this outlay. Begelly was a small tea estate adjoining Tangakelly, which the owner found too small to work as a separate estate.

It had been bought cheap for £1,081, and would be a valuable addition to Tangakelly. In conclusion he moved a resolution authorising the directors to purchase the Yoxford, Glenlyon and Stair, and the Begelly estates, or any part of them, with the buildings, machinery, implements, etc., at such price or prices not exceeding in the whole £38,581, payable in cash.

This was all very well, and it was agreed to; but the coffee business was another matter altogether. Mr. Reid was eloquent in praise of the Straits Settlement coffee. It had been proved that the soil and climate of the Straits were well suited for the growth of coffee. There were difficulties to be encountered connected with labor, supervision, and unhealthiness of climate; but if these were overcome he had no doubt that coffee-planting in the Straits would be a financial success. As to the incurring of any risk, he believed that they would know in two years with nearly absolute certainty how the scheme was going to answer, and the very worst that could happen would be to have £6,000 badly invested. If it succeeded—and he saw no reason why it should not—they would be in a splendid position to select the best land obtainable, and to develop a most remunerative industry. Regarding the funds to carry on the enterprise, they were aware that their reserve fund was derived from two sources, viz., surplus profits and premiums on the issue of stock above par. The surplus profits were available to equalise dividends, but the premium on issues of stock above par was not available for that purpose. This was a capital reserve fund, and they proposed to use it to plant coffee in Perak. The whole of the last

MR. DAVID REID IS COMPELLED TO ABANDON HIS COFFEE.

issue of preference stock, £40,000, had been placed at a premium of 15 per cent so that they had 6,000 to start with, and anticipated that this fund would supply all the cash required for their purpose.

But the coffee wouldn't go down. Sir William Gregory opposed the scheme. He said that the company professed to be a tea company of Ceylon, and he saw no more reason why they should embark in this speculative concern in the Straits Settlement any more than they should go in for a speculation in tobacco in Sumatra. To go into a speculation of this kind was not keeping faith with the original subscribers of the

company, who entered it as a tea company. When the company was doing well, it was but common-sense to let well alone. In conclusion, he stated that if the directors went into this speculation he should very shortly dissociate himself from the company. Captain Anderson backed up Sir W. Gregory. He was of the opinion that the company was going entirely beyond its sphere in entering the Straits Settlements to work. This rather staggered the directors; and, after some further discussion, the Chairman said that the directors had decided not to go forward with the scheme. And so the Ceylon Plantation Company will stick to their tea, and wisely so too, we think.

THE CEYLON PLANTATIONS TEA COMPANY.

There was a distinct Doric flavour about the meeting of the Ceylon Tea Plantations Company, held on Wednesday at Winchester House. The directors are all Scotch, the chairman is a Scotchman, the secretary—a real live baronet, by the way—is a Scotchman, and the shareholders look Scotch to a man. It is queer to find Scotchmen combining together to vaunt the virtues of tea, and in view of the insult which the fact offers to whisky, the only thing that can be said to justify the action is the quantity of siller they get out of it. But, perhaps, Scotchmen do not think so much of whisky as they used to, and we may come to hear of a teetotal version of "Willie brewed a peck o' maut." It might be started something in this way:

"Oh, Willie brewed some Pekoe hot,
And Rab and Allan can to tea."

Whether this be so or not doesn't matter very much to the Ceylon Tea Plantations shareholders, so long as they get big dividends. So far as this is concerned, the company seems to be doing very well, although the directors were somewhat severely taken to task on account of the paucity of information furnished in the report.

Scotchmen in their public capacity seem to be divided into two classes—the cautious and almost dumb dog, and the verbose and audacious heckler. Both classes were represented at this comfortable little meeting. The directors were the dumb dogs, and one or two of the shareholders were the hecklers. But there was no harm meant, and the meeting broke up in a state of good humour with themselves, with each other, and with all the world. Whether they adjourned bodily to Spiers and Pond's Restaurant, next door, and celebrated the occasion in draughts of their favourite beverage out of the tea-pot we are unable to say, as we did not stay to see.—*Financial World*, May 2nd.

MR. DAVID REID, SIR W. JOHNSTONE, AND MR. SHAND ENJOY THEIR TEA!

FISH CURING IN THE MADRAS PRESIDENCY.—The fish cured experimentally by Departmental Agency of the Salt Department to influence curers to follow the improved methods has, we are glad to learn, found ready purchasers and been more appreciated by the public, although sold at a higher rate than the ordinary bazaar salt-fish. Generally the well-to-do people purchase eagerly the departmentally cured fish as it is considered

very good, while the bulk of the poorer consumers care more for cheapness than for quality, and the fishermen consequently resort to the ordinary and cheaper mode of curing. But as the experiments are slowly, though almost imperceptibly, leading the public to appreciate the improved article, fishermen will, in course of time, be forced to adopt the improved method of curing.—*Madras Times*, Feb. 5th.

PLANTING PRODUCTS.

(From the Thirty-eighth Annual Report of the Ceylon Planters' Association, held 17th Feb. 1892.)

Tea.—The season has been a most favourable one for leaf, and estimates were generally exceeded. Owing to the great rush of leaf during the best flushing months, with a labour force insufficient to cope with it the resulting teas were poor, which in part accounts for the low average price ruling from May to September. This however may prove a blessing in disguise, as helping Ceylon tea the more to displace cheap China teas, and notwithstanding the large increase in shipments to London, viz. 19,988,075 lb. more than in 1890 according to the Chamber of Commerce returns our teas have gone even more freely into consumption. In Europe generally the advance made is most satisfactory, taking the Chamber of Commerce returns for 1890 as against 1891. *Austria* shows an increase of 70,326 lb., taking 74,426 lbs as against 4,100 lb. in 1890. *France* an increase of 1,934 lb. viz. 21,210 lb. against 6,276 lb. in 1890. *Germany* an increase of 30,821 lb. viz. 92,291 lb. as against 61,470 lb. in 1890. *Russia* an increase of 10,955 lb. viz. 11,230 lbs as against 275 lb. in 1890. *Spain* an increase of 16,995 lb. viz. 16,995 lb. as against only 600 lb. in 1890. *Turkey* takes 4,211 lb. or double that of 1890. In the East too progress is most satisfactory, *India* taking 620,161 lb. or an increase over 1890 of 175,530 lb., *China* and *Singapore* 166,659 lb., or an increase of 65,993 lb. over 1890. Elsewhere also the increase is satisfactory, *Mauritius* showing an increase of 66,283 lb., your teas practically monopolising this market. *Australia* takes 3,210,598 lb. or an increase of 650,697 lb. with room for more. *Africa* takes 70,828 lb. against 42,382 lb. in 1890 or an increase of 28,446 lb. Although the progress made in those countries is satisfactory, your Committee would point out to you that necessity still remains for pushing your teas to meet not only the yearly increasing output from Ceylon, but to gain a market to meet the increase from India. No opportunity should be lost to help those deserving of it to still further increase the popularity your teas have obtained in foreign countries by money, or grants of tea from the Tea Fund; which requires all the aid you can give it with the large field it now has to work in. Your best efforts should be made now more especially in *Russia*, *Austria*, *Germany*, and *France* to take advantage of the ground gained there. To *America*, exports direct, show a falling-off of 41,086 lb. probably more than covered by increased shipments from London. Here your Committee has called for your special help to support in a fitting manner your Commissioner to the Chicago Exhibition. Your best thanks are due to the Hon. Mr. J. J. Grinlinton for accepting the onerous duties you have imposed upon him in un-animously asking him to be your Commissioner. The total exports from Colombo, quoting the Chamber of Commerce returns for 1891, are 68,274,420 lb. tea against from the same returns for 1890 46,901,554 lb. or an increase of 21,372,866 lb. The average price in London was 10½d. as against 11d. in 1890 which result in face of the large increase in your teas placed upon this market viz. 19,988,075 lb. is not as unsatisfactory as might at first sight appear. Your Committee has again pleasure in calling your attention to the very successful dividends earned in all cases by your local tea companies.—This season has seen the floating of the Ceylon Tea Company, Limited, (under the patronage of the Planters' Association of Ceylon) for the purpose of helping to distribute your teas throughout the world, and your Committee feels that this venture should command your support as being capable of not only earning fair dividends, but as being a very efficient means of opening up new markets. Your Committee appends for purposes of comparison and reference statements furnished by the courtesy of the Hon. the Collector of Customs showing the total exports of tea for the years 1890 and 1891, to the United Kingdom and other markets.

Coffee.—Your old staple coffee shows a slight increase upon the previous season—a fact which

cannot however be recognized as any indication of permanent advancement. It arises from a large export of native coffee and might be attributed to the growing taste of the native population for tea, inducing them to consume the cheaper tea and so obtain in the market the higher rates ruling for coffee. *Liberian coffee* is now receiving some attention again and it is probable that its cultivation will be extended in suitable localities.

The exports of coffee from 1st January to 31st December during the past three years have been

1889	...	89,604	owts
1890	...	81,394	"
1891	...	82,324	"

Cinchona.—Very little interest is now taken in this product. Its cultivation of late years has not been encouraging to growers. The export of bark for 1891 reached 5,589,550 lb only, and it is anticipated that figures for 1892 will show a further large reduction. Most estates in the Uva districts, once considered the last stronghold of *Cinchona*, have now been cleared of this product, and cultivation of *Cinchona* bark throughout the island generally has been given up.

Cocoa.—The past year has been comparatively a favourable one both as regards crops and prices obtained, the export 1st January 1891 to 31st December 1891 being 20,532 cwt. by the Custom returns, which is about 4,073 cwt. in excess of the export of 1890, but is only 2,555 cwt. in excess of the export of 1887. This appears to show that the increase of production is extremely slow. The date of taking export figures (31st December) is not very well adapted for cocoa returns, because the time of heavy gathering varies somewhat and in one season more of the autumn crop may find shipment within the month of December than at another season. Taking, however, bi-yearly crops 1888 and 1889 31,180 cwt.; 1889 and 1890 34,891 cwt., and 1890 and 1891 36,958 cwt. for a fairer comparison, it merely shows the increase to be gradual and slow. Moreover, although the past year shows the highest figure 20,532 cwt. shipped, there is every reason to apprehend a great deficiency of crop for the spring of 1892 in consequence of the failure of blossom by reason of the remarkable and unprecedented fall of rain in the north-east monsoon which was so heavy and continuous that only a few day's fine weather in November availed for the sprinkling of a blossom. The gardens are reported as looking well and have suffered less than usual from insect pests. The natives have been stimulated a little to commence cultivating cocoa, but no very large areas have been planted up. Bitter complaints of thefts of produce have been made, but it is hopeless to expect improvement while sentences of lashing are remitted. Proprietors of large estates have extensively improved their drying arrangements, and increased care is being taken to secure the high position Ceylon cocoa holds in the market, and its natural merit is enhanced by the greatest possible pains and trouble to ensure its perfection in curing. Your Committee further appends a valuable report on the position of cocoa kindly furnished by Mr. Jas. R. Martin.

Cardamoms.—As your Committee reported to you last year, there is no present indication of any large extension of the cultivation of this spice, so it may be concluded that beyond the influence of any specific natural causes, suitable to their production, the export of cardamoms is not in the immediate future likely to be largely increased. Three-fourths of those exported are grown in the districts north of Kandy where the cultivation still continues to prosper. In some of the other districts of late, the growth of cardamoms has not been so generally prosperous during the closing season. Prices in the London market during the year have been well maintained. The exports of Cardamoms from 1st January to 31st December during the past three years have been as follows:—

1889	466,168	lb.
1890	395,576	"
1891	408,868	"

Minor Products.—During the past year some of the minor products of estate cultivation have proved

disappointing. Tobacco has failed to secure expected high prices, Cotton has been found suitable for the dry parts of the country, Annatto and Kapok have been overdone, Croton-seed is but little better, Ceara rubber has proved a failure, and Cinnamon remains depressed. Pepper has not yet yielded the large anticipated returns, and Vanilla is carried on in but a few places. Cocoa is to be found in one or two estates doing so well that the cultivation may possibly increase. Kola on the other hand is still in the experimental stage. An increased and well-deserved attention is being given to the growing of timber and firewood trees, while on some of the lower estates coconuts and arecanuts are being judiciously extended. With an ever-growing passenger and local demand fruit-growing might be carried on with advantage on all estates enjoying the privilege of cheap transport.

Cocoa, 1891.

I was last asked to report on cocoa in 1884, when it was suffering from the want of experience under which it was cultivated, and was probably lower in esteem than it has been before or since. The acreage thus cultivated, according to the "Ceylon Directory," was 10,000 acres, at present it is estimated by the same authority at 12,000 acres. The increase would be a small one if it were not remembered that about 1884 and in the succeeding years a considerable amount of the land planted was either abandoned or passed into other cultivations. The fact that the crop for 1891 was the largest recorded, indicates that we have profited by experience, and that cocoa is not generally cultivated under suitable conditions and in the soils required by the product.

The crop for the past year was 20,000 cwts. which indicates that a considerable acreage has still to come into bearing, for well-managed estates of any age are yielding much larger returns per acre than these figures indicate, and it would be I think, possible to mention cocoa planted on new land, and above nine years of age, the yield of which would bear comparison with what is reported from the West Indies. It is probable, therefore, that the export of Ceylon cocoa will increase. During the past year not only was the larger crop on record shipped, but the highest prices on record were obtained; these were maintained during the earlier part of the year, and until the Java crop of some 10,000 cwt. appeared in the market, and for the first time entered into serious competition with Ceylon. The cocoa from both countries is apparently of the same variety, and is cured in the same manner; for selling purposes the two crops may therefore be taken as one, and an unexpected increase of about 50 per cent of produce being thus thrown on one section of the market, a heavier fall than usual was established in the autumn. Notwithstanding this, however, prices are still much higher than they were some years ago, and cannot be regarded as otherwise than very satisfactory. The most important point to be considered is, wherein lies the superiority of Ceylon cocoa. It is the opinion of some, and amongst them are men whose opinion is entitled to the greatest respect, that it is to be found entirely in the case which we take in cultivation and curing, and from this it is argued inferentially that if the same methods are adopted by West India planters, the superiority of Ceylon cocoa will disappear. It is probable that this view is held at home, as at present there are no stocks of Ceylon cocoa in London, and what is purchased passes at once into consumption, which shows that for some reason buyers hope for a fall in prices. An examination, however of the different cocoas for sale in "The Lano" shows that the most marked difference between Ceylon and West Indian is not in the outside and general appearance, but in the "break," and that it is precisely in proportion to the lightness of colour of the "break" (or inside of the bean) of the Ceylon cocoa that it is valued.

The break of the West Indian growths, so far as I had an opportunity of observing, was invariably

very dark, brown or purple, which indicates that the cocoa is of the Forastero varieties, and every cocoa planter knows that no care in curing or cultivation will alter this characteristic. It is urged that Forastero cocoa shipped from Ceylon has fetched as good prices as those realised by the old Ceylon red, but the amount thus shipped has been very small, and it is probable that the name of Ceylon helped the sale.

I believe that I am correct in stating that no other cocoa known to commerce, excepting probably that now shipped from Java, is precisely the same as the old Ceylon red, that is, that no other cocoa bean shows the same creamy white colour when cut in section, and therefore no other bean is capable of showing the same light coloured "break" which is so much valued in ours. My opinion, therefore, is that so long as this is the case, a heavy fall in prices will only be established by increased production.

Forastero cocoa is now considerably in favour with planters, and although its produce will never in my opinion be of the same value as that of the old Ceylon red, still it has one inestimable advantage, viz., that it will grow and thrive when the other has failed, and it is therefore very valuable for supplying up clearings and for planting on the poorer portions of the fields. Planters need not be afraid of using it for these purposes, as the old Ceylon red is of such a pronounced variety as to be almost a species, and I have never seen or heard of its showing the slightest tendency to hybridism. On the other hand, Forastero planted with the Ceylon red shows a distinct though not universal tendency to change or revert to the Ceylon type. Thus the pods of a Forastero tree which for the first few crops are green, or yellow, will often as the tree gets older change gradually to red the only trace of their original color remaining about the divisions of the pod, which are yellow. This external change is accompanied by a change in the bean, the number of violet or purple beans decreasing as the pod turns red, until in the end only two or three will be found, the rest being very pale blue or white. Mr. Hadow of Kina Kellie was good enough to send me some pods from an isolated tree on his estate, grown at an elevation of over 3,000 feet. At first sight I took them to be old Ceylon red, the shape, however, resembled the Forastero and in opening them I found in each a few violet colored bean, the remainder being white or nearly so. As far as the history of the tree could be traced, it was a Forastero of about 17 years old, and Mr. Hadow informed me that the plants raised from its seeds showed almost every type of cocoa with which he was acquainted. There is no doubt that the pod had gradually changed to the Ceylon type, and the case is interesting as it points from the isolation of the tree to the change being effected by climate and soil. The point is a very interesting one and worthy of the attention of cocoa planters. JAS. R. MARTIN.

Jan. 23rd, 1892.

To the Secretary, Planters' Association of Ceylon, Kandy.

THE ORIGIN OF PETROLEUM.

Prof. Stickonberger, of Cairo, Egypt, gives in *Chemiker Zeitung*, 87, 1891, an interesting account of the present formation of petroleum in the Red Sea, the conditions being practically those of a closed sea of high salinity and in such a position and surroundings as to produce a superabundance of animal life, especially of the lower orders, and not sufficient scavengers to remove the dead bodies. Thus the high temperature produces very rapid decomposition of the latter, which give out large quantities of H. S. and a heavy brown oil. As there is no inflow of mother eye or brine of any kind in any part of the sea, these oils are not decomposed. The unabsorbed dead bodies being subjected to a continued intense heat, and in an quiescent body of highly saline water—sometimes containing as much as 73 parts of salt per thousand—undergo a process which may be considered petroleum fermentation.

This oil is absorbed by the porous rocks of the shores and coral reefs, and places are found where it

risos in them as in a sponge, and it can be seen in many places flowing out, owing to the pressure of the specifically heavier salt water which follows it in the porous masses and gradually expels the oil near the level of the sea. Before reaching the porphyry dike or wall, which lies parallel to the sea shore at Gohel Zed, the dense non-porous limestones are met with which prevent infiltration of the petroleum. Numerous vertical and lateral deep borings into these rocks have failed to find oil reservoirs from which the oil springs might be fed, and all traces of oil were lost as soon as the drill passed beyond the porous rocks.

The formation of petroleum in this manner has, of course, gone on since the present conditions were established, and would occur in the Red Sea wherever quiet coral bays exist. It is thus easily explainable why the sea between Sokotra and beyond Guardafui could be covered with a film of oil, the only puzzling point being that larger quantities of oil were not deposited in past ages. All limestone formations surrounding the Red Sea are more or less bituminous, those at Mokattam near Cairo only slightly so, which would point to previous infiltration, as also does the thin coating of so-called asphaltite found in the crevices in the Egyptian Tertiary formations. Figani and Frass called attention to these facts 25 or 30 years ago.

The present investigations by Oolsema and Jalczeicki have led to the definite proof that this petroleum process is still going on, that it is due entirely to animal decomposition (see also *Engineering and Mining Journal*, May 16th, 1891), and that no traces of coal or fossil vegetation can be found anywhere in the shore rocks containing the petroleum, which was verified by the numerous borings made. In the case of the Dead Sea similar conditions may have existed; but its present salinity is so great that animal life, except a few low orders, cannot exist in it. The asphalt found in it must be considered as dried petroleum. None of the geologists who examined the shores found the slightest traces of volcanic action; in fact, everywhere nothing but undisturbed Tertiary and Cretaceous formations. It must therefore be assumed that in bygone ages there must have existed conditions similar to those now found in the Red Sea in regard to multiplication of an animal life, which make the present generation of petroleum possible. It must be admitted, however, that a sudden influx of motherly might have come from the upper Ghor, which suddenly destroyed all animal life. Such a supposition is entirely untenable in the case of the Red Sea in its oil districts.

The Birket el Garm, in Fagonm, is a lake which receives none but the used irrigation water from the Nile, and has no outlet, and the incessant addition of salt by the flood waters of the Nile and the consequent evaporation, produces a slow increase in salinity; it is a lake full of life, at least as much as the Red Sea, but there are fewer animals of the lower orders, and many fishes, which immediately destroy all dead bodies, thereby preventing petroleum formation.

Thus the three cases are found as follows:—1. The Birket el Ghor, a lake of increasing salinity, with abundant animal life, production and consumption in equilibrium, prompt disposition of dead matter—no petroleum. 2. The small bays of the Red Sea, strongly saline, wealth of animal life, production and consumption disproportionate, scavengers insufficient, numerous decaying bodies; petroleum generated. 3. The Dead Sea; such excessive salinity that animal life is impossible; no petroleum but asphalt, indicating former conditions as under No. 2. All of these cases are found near the ends of the Cretaceous and lower Eocene periods.—*Engineering and Mining Journal*.

SOUTH WYNAAD NOTES.

Feb. 6th, 1892.

I was glad to see an account in your columns (shortly after the insertion of my last notes) of our new and terribly lively enemy, the *Saperda*. So far

from there being any "rarity" about the animal in Wynaad, I regret to say that, like the wicked man, he flourishes exceedingly, and unless the rain or some other calamity speedily overtakes him, we shall evidently have another study of insect life, hardly more agreeable than that of our own acquaintance, the Boror beetle. The worst of the *Saperda* is that his tastes are pretty well omnivorous, and his teeth equal to anything but the hardest wood. I have just recovered from the harrowing sight of a splendid scarlet passion flower reduced to a withered mass, all over my verandah. A young wild croton hedge is fast becoming a melancholy wreckage, whilst wild work is being done in various estates upon the *moorkahs* and the pepper plants. But your timely warning showed us how to trace the mischief. In every sawed off branch may be found several holes pierced deep into the wood, at the bottom of each of these lies a small yellow egg. The only remedy evidently is to burn all the destroyed wood, and my garden coolly has stringent orders to collect and speedily reduce to ashes, all the evil works of the *Saperda* that he may come across. But, of course, this would be more difficult to do in the case of a whole estate, especially when the top branches of tall pepper vines were affected. The correspondent from South East Wynaad, alluded to in your Planting Notes, mentions that the same pest has attacked his tea, but I have not heard so far that the tea-growing in this neighbourhood has suffered. The last complaint I have heard of here is of the porcupines. On one tea estate these animals are an absolute nuisance, coming at night (so I am pathetically assured!) "in troops," at a rate in sufficient numbers to do considerable damage; for they dig up fine old bushes, presumably to devour the roots, and it is next to impossible to catch them. Spring gnus, or a cordon of coolies making night hideous by banging kerosine oil tins, succeeds for a time, but the least relaxation of vigilance brings back the enemy, more hungry than ever, and their travelling powers are so considerable that they are, so to speak, all over the place at once. Apropos of porcupines, I heard once of a pair being destroyed by "Rough-on-Rats." A lady, a friend of mine, who is exceedingly fond of her garden, was dreadfully troubled by these animals, and tried in vain to get rid of them. Some one told her they had a passion for pomeloes, so she artfully treated a very fine one with "Rough-on-Rats," and strewed the pieces about. In the morning, two porcupines were found stone dead. This might not always prove equally successful, but the idea is worth taking a note of.

Rumours, many and various, are floating about regarding tea prospects in Wynaad, and there is very good reason to believe that the next twelve months will see sundry considerable changes in the district. We were glad to note in your columns the probability of the Tamhacherry Company going in for tea. I had heard of this some time ago, and the prospect, if realised, will be warmly welcomed in Wynaad, as the reactivation of this large block of estates, those parts of them, at least, which have been abandoned for coffee, will make a hopeful stir in our small planting world, and inevitably lead to more prosperous days. Tea, Liberian coffee, and pepper, and perhaps cinchona, are almost bound to be our renovators, and should these new enterprises be vigorously carried forward, there can be but little doubt that in eight or ten years' time, Wynaad will once again become the home of prosperity. But it is a critical time with us, and the ten years more will show far from universally satisfactory results, unless energy, enterprise, and money come forward and help us on. On the other hand, I am convinced that the thing only wants starting. The land is there, splendidly suited for either tea or Liberian, and this has only to be proved practically, as indeed it has experimentally, to make the minded public understand the actual value of land which circumstances, chiefly represented by leaf disease, have laid waste. Happily the stir has begun, and as I said before, we may hopefully anticipate some beneficial changes in the district during a not far future.

Crop is pretty generally over. If I am to tell the undecorated truth, I must reveal the uncomfotable fact that a great proportion of the coffee on some estates has been very light. Pretty nearly all have suffered more or less, and these estates which caught the early rains last year seem to have been most effected. Many of us can remember a similar occurrence, in (I think it was) 1873, which was also attributed to unseasonable rainfall. The rise in cinchona has been a great comfort and encouragement to us; and everybody is shipping bark as early as possible. The drought is causing us serious anxiety. Not a drop of rain has fallen since the beginning of November, and the young plantings are suffering severely. The whole country looks fearfully parched, and the mountain sides are blackened by fires. The heat in the middle of the day is very great, and this, combined with the dust and smoke, are anything but pleasant. We hear bad reports of the approaching famine; grain is rising very much in price. Grain, which was formerly four rupees eight annas the pullah, now costs eleven rupees; ragi is so dear, that the coolies are buying rice brought up from the Coast. It is sad to think how things will be a few months later. I saw an unmistakable "famine cooly," the other day lying by the road side, and the sight was a sad one, recalling the terrible memories of 1877. Our coolies are very anxious to be kept on later in Wynnad. Unfortunately most of us are equally anxious to pay up our gangs, and retrench. The spike is beginning to show up, and possibly as far as that is concerned, it would be better for the rain to be delayed until March, though one does not like to think of the fate of our baby cinchonas and coffee, should the drought so continue.

The Punnians about here are becoming very troublesome and daring. They are driven to desperation. Decidedly, Coffee Arabica is what old nurses would call, "contrary." We coddle it up with every sort of tonic, we shade it carefully, and weed and prune, and it rewards us with a golden glory of leaf disease and surprise packets, in the shape of bushels of empty beans. But an account reaches us of an abandoned estate which had grown up into scrub jungle, knowing nothing of cultivation for many years. It was remarked that some of the old coffee trees had crop on them, and the happy thought occurred to grass knife about them. This led to further discoveries and ended in a gathering in of something over ten tons of coffee, perfectly sound. It is positively aggravating to hear of such things, and really in extraordinary defiance of all our experience and teachings.

Native proprietors are becoming very keen for Liberian coffee, and eagerly bring, as they say, "money in the hand" for the purchase of seed. A great deal of it is also being planted on European estates. The drought affects the young plants a good deal, and even the full grown ones seem to feel it. But this is not surprising, as every living thing is beginning to suffer.—*Madras Times.*

MESUA FERREA.

At the time when this tree is pushing forth its delicate pink-coloured young growths, many people are misled at first into supposing them to be flowers. Owing to the dry weather in May, 1891, no such growths were to be seen, but flowers instead were being produced. These are by no means unlike the Dog Rose of English hedgerows, their four large petals are white, the centres filled with yellow stamens, and fragrant. Before expanding, the flower-buds are purplish-pink, giving quite a colouring to the leafless, or partly leafless, terminal branches which bear them. The leaves are opp. site, ovate-oblong, long pointed, and so densely set that it is nearly impossible to see through the tree from one side to the other. The under-side of the leaf is very glaucous, but green above, and card-board-like in texture. In shape the tree is oval, with a very even outline, to be compared in this respect with our specimen of *Canarium oommo* (Parrot nut). The hardwood of *Mesua ferrea* is known amongst other woods by the name iron-wood. During the past three years no fruit has been borne; whether any has ever been produced there is no record to show.—*Gardeners' Chronicle*, Jan. 30th

COFFEE LEAF DISEASE.

It will be remembered that after the death of Dr. Barclay, one of the members of the Leprosy Commission, the Wynnad Planters' Association addressed the Government with a view to obtaining the services of an expert to investigate coffee leaf disease, and that Dr. D. D. Cunningham was asked to undertake the work. Sir Edward Buek, writing to Sir Charles Bernard at the India Office, asked him to ascertain whether Dr. Cunningham, who was on leave, would be willing, on such terms as might be acceptable to him, to undertake, during the next two years, the investigation of the coffee disease which was begun some years ago by Mr. Marshall Ward, and to inform him that this investigation would not preclude him from travelling elsewhere during a great part of the year and prosecuting enquiries into any cognate questions which he might like to take up. The proposal, Sir Edward said, originated with the Madras and Coorg authorities, who had both independently urged the Government of India to assist them in taking action. If Dr. Cunningham was unwilling to entertain the idea of his own deputation on this mission, the Government of India said it would probably move the Secretary of State to send out another European expert. The study of the particular class of pests to which the coffee parasite belongs was one of great difficulty, and had been taken up by very few scientific investigators. It was therefore most important, Sir Edward said, that a true expert should be selected and not one who, like Mr. Marshall Ward had only entered on to the threshold of this particular domain of science. Dr. Cunningham went to see Sir Charles Bernard in London, and the following is the substance of what he told him. He was not included, he said, to take up the work himself, although it presented very great attractions, on the following grounds viz. (1) he was in the middle of a series of investigations in regard to the bacteriology of cholera which he and others believed to be important and promising of practical result, and were he to abandon them, he thought there was no likelihood of their being satisfactorily carried out; (2) although he fully recognised the value and importance of the proposed investigations into the life history of the coffee blight he felt convinced that these referred merely to the purely scientific aspects of the question, and that the results of the enquiry were likely, however scientifically successful they might be, to be entirely disappointing from the practical coffee planters' point of view. Dr. Cunningham then went on to say—

"It is most desirable, from the purely scientific aspect, that it should be determined whether *Hemelia* possesses all the forms of fructification normal to the cycle characteristic of the *Uredinea*, but even were a resting fructification discovered and all questions of Autoconiousness or Heteroconiousness settled, I do not believe that any important advance in regard to the practical treatment of the pest would have been made. Coffee is a perennial crop and one which at all seasons presents leaves in a suitable condition for infection by the predacious spores—the typical *Hemelia* spores—so that there is no necessity for the presence of any resting spores to secure the continuous propagation of the disease. So far as one can see at present, the only cure for the disease would lie in the total abandonment of coffee cultivation for a period of one or two years so as to deprive the blight of the soil necessary for its propagation, and even this, of course, would not provide absolute security against its recurrence, if, as appears probable, it be an invasive species proper to jungle products. Allowing, however, that this be the only promising treatment in the present state of our information, I cannot see that the discovery of resting spores or other forms of fructification would in any way affect the question or at all advance matters, for the uredinous fructification alone is sufficient to secure continuous propagation, and therefore, in any case, the treatment would have to be directed to interrupting this continuity. Having

explained to Sir Charles my reasons for declining to undertake the work myself I told him that I believe that Mr. George Murray, M.A., who has for some years had the charge of the Cryptogamic section of the Botanical Department of the Natural History Museum (British), would be by far the best man to secure, or failing his being inclined to accept the appointment, to advise in regard to a suitable worker. Mr. Murray is a very distinguished practical Cryptogamist and has given ample proof of his qualifications by his publications."

Under the circumstances mentioned by Dr. Cunningham the Government of India left it to the Madras Government to decide, "in consultation with the Wynaad Planters' Association," whether it was worth while to continue endeavours to obtain the services of an expert. If this was considered desirable, and the Government of Madras and the Association were prepared to provide the funds required, the Government of India said it would be prepared to obtain the services of Mr. Murray, or any other competent enquirer, unless the Association would prefer to make its own arrangements in the matter. The Madras Government—apparently, however, without consulting the Planters' Association—has declined to incur any expenditure in engaging an expert. This decision will probably not commend itself to the Association in particular, nor to coffee planters in general, but the emphatic opinion of Dr. Cunningham that no benefit was likely to accrue to the planters from the proposed investigation no doubt justified the Government in refusing to extend its support in the direction indicated. Numerous reports on the specific diseases to which coffee is liable have been published, notably those by Marshall Ward, Eldie, Harman, Forbes Watson, Morris, Cooke, Balfour, etc., but all these scientists have been practically baffled when they came to tackle that insidious fungoid disease *Hemelia vastatrix*. Every effort has been made to find a cheap and effectual cure; but all to no purpose. Proventives have been discovered, but no curatives, and we fear that the coffee planter must continue to suffer in pocket from the ravages of the leaf blight.—*M. Mail*, Feb. 12.

[Dr. Cunningham's utterances were commonsense and honest. The interest of further inquiry would be purely scientific. As we have frequently stated, a mixture of lime and sulphur will destroy all the spores it reaches, but it cannot reach all, and the power of reproduction is enormous.—*Ed. T. A.*]

INDIAN TEA DISTRICTS' ASSOCIATION.

A meeting of the association took place on Tuesday, when representatives of the following tea concerns were present:—Assam, Jorohant, Jokai, Tiphook, Noakacharee, Darjeeling, Assam Frontier, Dejeo, Land Mortgage Bank, Brahmaipoora, Chergola, British India, British Assam, Kalunc, and other estates. The Ontario proposal to form of Tea Districts' Labour Supply Association was the principal subject under discussion. After due consideration, the following resolution was adopted:—"That those present at this meeting approve of the proposal to form a Labour Supply Association on the lines suggested, and agree to give the scheme their support."

Mr. Stanton (Gow, Wilson, and Stanton) brought forward the question of foreign tariffs as affecting Indian tea, and the following correspondence on the subject was read to the meeting:—

"Ernest Tye, Esq., Secretary Indian Tea District Association, St. Mary Axe, London, E. C.—Dear Sir,—You will be interested to learn that the new French Protective Tariff, which has now come into operation, makes no change in the duty on tea entering that country. This is in a measure satisfactory, as placing tea in no worse a condition than it was before, in spite of adverse changes in the tariff of other articles. Possibly, therefore the efforts of the Indian Tea Districts Association may have met with a partial amount of success. It will interest your association to know that we have written a letter to the Trade and Treaties

Committee at their suggestion regarding the approaching termination of the present commercial treaty with Spain. They also inform us that it would strengthen their hands in negotiating matters if they received letters from the Indian Tea Districts' Association and the Ceylon Association, thus having representations from those bodies most interested in tea grown on British soil. We therefore bring the matter to your notice in the hope that you will see your way to writing the Trade and Treaties Committee at the Board of Trade, urging upon them the desirability of taking such steps as they may be able for the purpose of obtaining some reduction in the present duty. We may add that the present duty on tea entering Spain is about 10s. per lb. under the most favoured Nations Clause, and about 1s. 2½d. for all other countries. The annual consumption of tea only amounts to about 200,000 lb. The loss (if any) to the Revenue by a reduction in the duty could therefore, be only trifling. The Commercial Treaty will also shortly be expiring with this country and Portugal, where the duty imposed upon tea is about 1s. 10½d. per lb., but we fear from information obtained that there is very little chance of any reduction being made.—We are, dear Sir, yours faithfully,

GOW, WILSON, AND STANTON."

"To the Secretary, The Trade and Treaties Committee, Board of Trade, Whitehall, S. W.—Dear Sir,—In view of the speedy termination of the Commercial Treaty at present existing between the country and Spain, we venture to place before you a suggestion that the present high duty which is imposed upon tea entering that country might be reduced with results probably beneficial, not only Spain, but also to the tea industry, which is now a great extent a British industry, owing to the large quantity grown in India and Ceylon. The duty upon tea entering Spain is about 10s. per lb. for nations coming under the Most Favoured Nation Clause, and 1s. 1½d. for other countries. The quantity of tea annually consumed in Spain is about 200,000 lb, a quantity which brings in so insignificant a sum for duty, that very little loss could result to the Spanish Exchequer by any reduction in the tariff, whereas a reduction in the rate of duty might cause material increase in the quantity of the article consumed, and eventually result in an actual addition to the national revenue. We venture to bring this matter before you in the hope that the influence of the Trade and Treaties Committee may be brought to bear on the Spanish Government with a view of some reduction being made in the duty.—We are dear Sir, yours faithfully, (Signed) Gow, Wilson, and Stanton.—*H. and C. Mail*, Feb. 12th.

EUCALYPTUS FOR INFLUENZA.—The remedies recommended for the cure and prevention of influenza are as numerous as they are varied. Accumulating that come at least may prove to possess the effective curative and preventive qualities generally claimed for all, we quote the following from a letter addressed by a correspondent to a London paper:—"In the office of the Royal Insurance Company, Lombard-street, only a young messenger is away through the influenza, and this comparative immunity from a disease at present so general is thought to be due, in a great measure, to blotting paper with a few drops of eucalyptus oil on it being daily placed about the various departments. This idea of the efficacy of the precaution is strengthened by the fact that when the epidemic was raging two years ago, while in one department, where it was found the oil had not been used, four or five out of about twenty-five clerks were attacked by the influenza, in the other departments, where there were three or four times the number, hardly a single clerk was away after the precaution was adopted. No doubt this precaution is now not novel; still, it may be well for those who do not know of it to try its efficiency."—*Egyptian Gazette*.

CURIOSITIES OF TEA TASTING.

The Tea Tasting Committee of the Islington Workhouse should, one would think, have been elected on the ground that it, or some of its members, were possessed of some practical knowledge of the matters with which it was supposed to deal. Unfortunately, in making the selection, it would seem to have been thought that no expert knowledge was demanded, and it may probably be concluded that similar Committees appointed by the Boards of Guardians charged with parish relief throughout the length and breadth of Great Britain are, as the rule, possessed of no greater experience in such matters than was that of Islington. There can be no doubt that, if such a conclusion be correct, a great deal of harm may have been done to the reputation of much of the Ceylon tea sent home, and a wide field available for its consumption denied to it through a very unpardonable ignorance. We doubt exceedingly if any special Committee had been appointed by the Islington Guardians to report on teas alone. There is generally in connection with every workhouse, we believe, a Supplies Committee appointed, which deals among other things with all the provisions obtained under contract from the several purveyors. Now we can readily understand that gentlemen appointed for the performance of such a duty might be sufficiently well-qualified by their experience to form right opinions as to the quality of the beef, mutton, pork and bacon, and other items of a like nature supplied for the maintenance of the inmates of a workhouse; but it must be quite a different thing when it becomes a question of judging of the relative qualities of teas, a function which, to be properly carried out, demands the services of the most highly trained and naturally-gifted experts. We see the result of the ignoring of such qualifications in this, particular case of the Islington Guardians; and, as we have said, there is every reason to fear that their instance is but one of a very large number. The facts of the case seem to be that this Committee rejected samples of Ceylon tea submitted to it because the infusion of these, after being permitted to become cold, became of a milky colour. Any expert in the business would have known that this was merely a chemical change due to the inherent strength of the tea, and that it afforded no indication of the inferior quality which the committee assigned to it. Apparently these wisecracks of Bumbledom, without seeking any outside opinion qualified to confirm or dispute their suspicion, took upon themselves to characterize their finding as a "curious discovery." It was, indeed and in truth, exceedingly "curious." Parish authorities are not generally credited with being overburdened; either with commonsense or with expert knowledge, and certainly in this case they exhibited neither one nor the other of those qualities. Commonsense must certainly, had this committee possessed it, would have informed its members that, on a point of quite, novel experience it would be desirable to consult with someone duly qualified to advise them. This view did not, however, appear to strike them; and they accordingly proceeded to give publicity to their finding, a publicity which proved to be most fortunate, as it resulted in a correspondence a paragraph summarizing the intent of which is given in our London Letter by this mail. The *Daily Chronicle*, the journal which has afforded this paragraph, is a paper which is very widely read, and has a particularly large circulation among the class from which the members of Boards of Guardians are mainly selected. The effect of the paragraph will almost certainly be to bring home to

the minds of the Supply Committees of such boards that they are not infallible, and that it would be a fairer course, and one that in the end must prove to be by far the most economical, if in all such cases which present conditions they themselves are unable to explain, they should seek for competent advice rather than by a hasty decision give rise to an unwarrantable prejudice that, as in this instance, may be productive of serious injury to particular trades. The fact is that tea-tasting should be made a subject for instruction to Committees of this character. Here we have a case of men waiting for the tea to get cold before they passed judgment upon it! No professional taster, or, indeed, anyone possessed of the slightest acquaintance with the peculiarities of tea, would have committed such a stupid blunder. If mistakes of this kind can be made, we should not be surprised to hear that all the samples submitted to the Committee, whether of Indian, Ceylon or China, were exposed by it to the same period of infusion. It is not at all unlikely that this may have been from five to ten minutes, and we all know that the longer period is far beyond what should be given to either Indian or Ceylon teas. We have a right to complain that vestrymen should be permitted to exercise functions for which they are wholly unqualified. Samples of such delicate articles as tea should be judged of for them by unbiassed experts. Until such a course becomes the rule, we may expect to hear of blunders like this being perpetrated, and as a great tea-producing colony we are justified in protesting against public acts likely to prove injurious to our staple product.

THE PATENT PAPER LINING FOR TEA BOXES.—

Mr. Maitland Kirwan writes to us on 10th Feb. — "I am sailing on Friday next by the S. S. 'Ormuz' for Ceylon. I shall not be more than a very few weeks in your island, during which time I shall be pretty fully enjoyed in my various interests I am connected with there, but should any information be required by your planting community or others, relative to the new patent paper linings for tea chests, I should be very pleased personally to meet any one requiring such. The 'Ormuz' is due in Ceylon on 9th March; letters will find me at the G. O. H."

A CINCHONA PIONEER.—Dr. Hasskarl, the scientist, who, many years ago, succeeded at great personal risk and with much trouble, in obtaining young cinchona plants from South America and carrying them to Java where they formed the nucleus of the plantations now existing in the island, now lives in retirement at Cleve, in Germany, on the Dutch frontier. The doctor recently celebrated his 80th birthday, and is still in the possession of good health and of all his faculties.—*Chemist and Druggist*.

THE RICE CROP IN BURMA.—The report received from the local Administration on the prospects of the crop on the 31st January 1892 is as follows:—

"The area under paddy cultivation is now estimated at 4,174,514 acres, or 258,356 acres more than the actuals of last year, and 66,982 acres more than the estimate of last month. The estimate of last month is unchanged in Akyab, Thongwa, Hanzada, and Shwegyin. The annual estimates of last month are unchanged except in Pegu, Tharrawaddy, and Prome. Pegu now reports fifteen annas against fourteen annas last month, while Tharrawaddy and Prome report fifteen annas and thirteen annas respectively, against thirteen annas and fourteen annas last month. There are increases of 38,535 and 25,505 acres in the estimated areas under cultivation in Pegu and Prome, and a decrease of 9,090 acres in Bassein. The changes in other districts are small. It is estimated that there will be available for export 1,250,500 tons of cargo rice equivalent to 21,194,915 cwt. of cloaved rice including what is required for Upper Burma."

A TRIP TO THE NEW HEBRIDES.

By C. P. A

When people as a rule go for a trip, they generally at least know the ports or places they are to stop at; but on this occasion, we knew little more than that we were bound for the New Hebrides and would not get much information concerning them. We left with the idea that we were going to a very little known (at least to the outside world) and uncivilized country where savages abounded and cannibals are still to be found: this however only gave it an additional charm. Our party consisted of five bound for the Islands on different vocations, to civilize the heathens, take views of the country and natives and to get some information of this out-of-the-way part of the world. One who has written of "the greatest thing in the world," and is one of the great men to whom we owe much, it is to be hoped will give us some of his impressions received there. I allude to Professor Drummond, who was one of our party.

We left Sydney on the 19th June with a fair wind and fine weather in the A. U. S. N. Company's S. S. "Rockton," having a genial, kind and careful commander, and were very comfortable on board. The weather got warmer every day. Time soon passed, talking of the different things we expected to see, looking at the shoals of flying-fish, admiring the beautiful sunsets, the description of which is a task beyond me, their brilliant colours changing over few seconds, and listening to stories of the natives told by one of our party who had been in the Islands before. One story I remember gave us rather a bad impression of the natives. A woman having died, her child was to be buried alive with her; the missionary offered to take the child and bring it up, and told them of the sin and crime they were committing, but it was no use, it was their law and the child was buried with her. Shortly after 8 o'clock in the morning of the 23rd we sighted Kogi Peak, New Caledonia, and soon the lighthouse was in view. It is on a little island, covered with scrubby but green vegetation and surrounded with a white sandy beach. Leaving it behind us, we passed between two coral reefs, one the shape of a half moon and the other of a circle, the colour of the water inside being of different shades according to the proximity of the reef, the sea being as smooth as glass inside. We passed through a narrow entrance between two islands and almost at once came in sight of the town of Noumea, the chief town of New Caledonia. The harbour is small but a good one. As we went in the convicts were to be seen at work, some mounting a gun on one of the hills; we steamed right up to the wharf and made fast alongside. The town is built on a flat with the hills varying from a few hundred feet high close to the town to about 2,000 in the distance. A few of us went ashore intent on some purchases we had to make, and were agreeably surprised to find some English shops where one could buy almost anything wanted and at reasonable prices. Next day after visiting the market early in the morning we took a drive some three or four miles into the country to a sort of farm-house, where we had some good coffee and oak brought us by an English woman, who was very kind and attentive, giving us a bunch of flowers from her garden where roses, hibiscus and collinses were growing luxuriantly. As we drove out the view was not particularly pretty, but on our way back as we approached the harbour, it was very fine. The climate was enjoyable, the temperature then being about 65 or 70 deg. in the shade. Gardens are now being made in the centre of the town square and the sides of the streets about it have been planted with flamboyant trees, which will in time give a pleasant shade. Plenty of natives were to be seen about, in most cases doing nothing, except the policemen who were natives and were busy examining the cargo and ship to see if there were any convicts escaping, as one had previously been put on board a ship in a case as goods. We left Noumea on the 24th and steamed for some time close along the land; it was very interesting going through the narrow passage called Havanah, passing many small islands and coral

reefs. During the night we passed close to Maré, one of the Loyalty Islands, and arrived at Anietyum, New Hebrides, next day, the 25th, still having delightful weather. The country is very similar in appearance to parts of Ceylon, the shore being fringed in places with coconut trees, the hills rising at the back to 2,788 feet high, two peaks called the Twins being that height covered with luxuriant vegetation and forest. After transshipping our goods and chattels to the S. S. "Truganini" of about 200 tons and called after the last Queen of Tasmania, I believe, we went ashore and were introduced to some 20 or 25 missionaries and ladies who had come down from the different islands to attend the Synod of the Presbyterian Mission which was then being held; many resolutions were passed which will greatly tend to the civilization of the natives and the advancement of the country. One or two of us in the evening took a stroll to the saw-mills managed by Mr. Martin who was particularly kind and hospitable; we saw the timber being sawn up at the mills worked by steam, some very fine, one kauri plank being 4 feet broad, also another timber boomana very much like teak. The natives here, about 850, are all more or less civilized, a good many of them speaking pigeon English. What struck me as most peculiar, the natives all came forward and shook hands with us, in some cases rather objectionable, and at meetings in some of the islands where one had to shake hands with a hundred or more, it became a nuisance. We sailed on the evening of the 26th and arrived at Tutuna Island at daybreak on the 27th, having laid to part of the night. We all went ashore and went up to the missionary's house, where we had just time to have a cup of good tea and some cake, when we had to be off again and sailed at 7:30 a.m. We arrived and anchored in Sulphur Bay, Tauna Island, at 2 p.m., the captain bringing the ship here to allow our party to see the volcano Yasner. Some fifteen of us, our party having been augmented by the missionaries from the Synod returning to their several islands, were soon off in a boat for the shore; but had to stop some hundred yards or so from the beach, owing to the appearance of the crowd of natives, which was anything but inviting, all being armed and flocking down to the beach. It was but for a short time only, as the missionary of the island who was with us in the boat soon smoothed matters and explained the object of our visit. Their arms, mostly Snider rifles, though not as effective in their hands as the poisoned arrows which some of them carried, were soon laid down, and after a little time spent in arranging for a few natives to come with us, there being some difficulty about the matter as they were at war with another tribe, we started for the volcano about 2 miles distant. After a pleasant walk through the lush, luxuriant in tropical vegetation we arrived at the plain surrounding the hill made desolate by the scoria which had fallen from the volcano and sat down previous to making an effort for our climb. I here had time to notice the repugnant and savage appearance of the group of natives who had come with us. After a quarter of an hour's rest or so, we started up the hill, which is put down in the chart as 600 ft. high, but seemed 1,000; on our way up we passed several sulphur springs, the fumes from which were not refreshing. We were well repaid however for our exhausting climb when we did get to the top. Looking down into the depths below from the edge of the crater, we saw the red hot mass of lava seething and boiling in the cauldron at the bottom, the smoke arising being of several colors as it was between us and the sun, while at intervals of different duration, the lava was thrown up half way to the top of the crater and again with a roar that made the hill tremble and shake great bolts of red hot lava were thrown high into the air. Fortunately the wind was in our favor. Some pieces I should think were thrown quite 1,000 ft. above where we stood, one red hot bolt falling on the spot where but a minute before one of our party had been sitting and from which he lit his cigar. After taking a relic in the shape of a dry drop of the crater, we descended on the opposite side to that

on which we went up. When we got down we walked along the shore of a freshwater lagoon about 80 acres in extent and reached Weasisi Bay, 8 miles or so distant at 8-30 p.m., the ship having come round from Sulphur Bay in the meantime. We went on board at once as news had arrived that the missionary's wife on Erromanga, the next island, was seriously ill, in the hopes that we might start away at once; it could not be ascertained, however, but we sailed some hours earlier, than was originally intended and arrived at Dillon's Bay, Erromanga Island, shortly after noon, and were glad to hear on arrival that the lady was better and particularly as her husband was a great favourite on board and was universally liked and esteemed. A few of us visited the graves of the missionaries, Williams and Gordon, who were killed some years ago by the natives and a photograph of the grave and tombstone was taken, with the native who is a son of the man that killed one of them leaning against the stone. It is very pretty at Dillon's Bay, about the mission-house, the steep hill on one side and the lofty trees here and there and grass land on the other, with the little cove into which a freshwater river runs forming a delightful scene. Some availed themselves of the opportunity of getting a freshwater bath in the river, while one was intent gathering curiosities and purchasing odds and ends, amongst others the native women's dresses, which are uncommon and rather to be admired, made of pandanus leaves which are strung singly on a cord, it taking some dozen or so of these to form one dress; the leaves of the outer skirts sometimes having a pattern with the ends coloured. Before leaving we were entertained in a room apart from the mission-house by our kind and hospitable host, who although he had his own troubles insisted on our having something to eat before we left. Amongst other shrubs and flowers I knew well, I noticed here lantana and the bonganvillea creeper. We sailed at 6 p.m. and anchored in Port Vila, Efati or Sandwich Island, at 8-30 a.m. the 29th. I went ashore with some others and called on Monsieur Chevillard late Mayor of the French Commune there, which has since collapsed. He entertained us most hospitably and took me over his coffee and coconut estate called Franco Villo and kindly allowed me to take from his garden some eucharis lilies and roses for the ladies on board. It was rather warm here, the temperature in the shade being about 88°. The French Company have large estates here, but owing to want of time I had to put off my intended visit. Next morning I went ashore again and got a good fern, the first for my collection. We sailed at 10-30 a.m. on the 30th June and arrived at Havannah Harbor, same island, at 2 p.m. This harbour is well protected by several islands and almost land-locked, but has not such good anchorages as Port Vila. After visiting one or two stores here we went to see a garden belonging to a Frenchman where there were various kinds of vegetables and were surprised to see even carrots and turnips doing well. We then started for the missionary's house and on the way passed through the property of the French, where some time ago they had troops stationed. The place has since been allowed to grow up and the buildings are untenanted. After spending some time at the mission-house, where we were made very welcome, we went on board and sailed at 6-40 a.m. for Tonga. *En route* we passed the labour brigantine "Helena" with 50 recruits on board, who cheered in their own way as we passed them. This traffic I learn is to be stopped at the end of the year. It was very enjoyable stowing along, with many islands in sight. We arrived at 2-30 p.m. and soon went ashore, most of the party going to the mission-house, two of us taking a walk for about two miles into the forest, which we enjoyed very much. The peeps of forest scenery were beautiful, the trunks of some of the great forest trees being half covered with different ferns and orchids and the branches festooned with creepers; the bunches of wax-like flowers on them filling the air with perfume. I was here able to make a good addition to my fern and orchid collection. I was loath to leave such a beautiful spot and would have wandered on regardless of the lapse of time, had not one of the natives suggested our return. A good

many of the natives here do their own trading in copra direct. While laying at anchor here the islands of Api, Mai or Three Hills, Makura, Matassa, and Emau were in sight. We sailed at noon and arrived at Sakow anchorage, Api Island, at 2 p.m. After staying here a short time we sailed again for Bununba to land a missionary and his wife, this being their station, and from whom I got an invitation to stay on my return. At 6 a.m. 3rd July we were off again for Big Bay on opposite side of the island, going between the islands of Api and Leminu, which are covered with dense vegetation and there is a white beach, also between the islands of Panama and Leperi on one side and Api on the other. Loperi is a volcano, conical and rising abruptly to the height of 5,000 feet, but is not active at present. Great shoals of flying-fish were to be seen as we went along here. At 9-35 a.m. we anchored in Big Bay and soon put the missionary and his house ashore, he being the first missionary to be settled here. As we went ashore, one could not help noticing the scene before us, high and broken land covered with tropical vegetation interspersed with coconut trees, while on the right of us was a very large reef over the edge of which the sea was breaking, while the natives were to be seen coming to the beach to welcome the missionary, the whole forming a novel sight. We could only get to the edge of the reef in the boat, some distance from the shore; as the tide was out, the ladies were carried over the reef by the natives and the rest of us waded. The natives here as elsewhere were armed with Suider rifles and bows and arrows, some of the arrows being poisoned which were carried in cases. The natives said they were glad that a missionary was going to live there and that war would now cease: this sounded very much like bluff. After the usual shake hands which some of them had learnt elsewhere, we started away from the hill on which the new mission-house was to be built. We were very tired and hungry when we got to the top, tucker not having been brought with us. We got some fine large bananas roasted in their covers on a fire which the natives soon had ablaze. When we got to the beach we found refreshments had been sent ashore, which we soon did justice to. Meantime the natives were busily engaged floating the timbers of the house ashore and carrying them up the beach; they were very willing and merry over it and were particularly interested in the live stock that came ashore, viz., a cat and a goat, the latter resisting all efforts of the natives to make friends with him, but at last by giving him a good scope of rope they managed to secure him to a tree. Before leaving, tents were erected as a temporary home for the missionary and those who were staying to help. After finishing the cargo and saying goodbye we sailed at 9 a.m. and anchored in Port Sandwich, Malliceo Island. The French Company have a small pier here and some good stores built of stone. After delivering mails and transshipping one of our party to H. M. S. "Royalist" which for Oulea, Sassaon Bay, stopped there for a short time, at Pangkumu, at Port Stanley, which has a good but small harbour protected by two islands Uripio and Urikire, also at traders' stations on Rano and Walo Islands, while at Walo, one of the missionaries and myself left the ship's party and went away into the bush, in the direction from whence came sounds of a sing-sing. The nearer we approached, the louder the yells became and the less inclined did I feel to go on, and suggested to my friend, that we had better go back, but as he said it would be well worth seeing as we went, and after a walk of about a mile and a half we got to a large place, cleared of forest, in the form of a square, at one side of which some 60 or 70 men and boys were seated slogging and beating time with their hands and feet. Yells were heard in the forest in the opposite direction from about the same number of men, who presently with a rush came out of the forest and advanced towards those sitting down, beating regular time with their feet. Before they reached this front line they retreated, and again advancing with a yell charged in regular order amongst the files of those sitting down, then suddenly turning to the right they left them and turning again they advanced in the opposite

direction, the front rank going to the rear in each separate advance, the whole winding up with a terrific yell as they finally retreated to the forest. This game, no doubt, would have been kept up some time longer, were they not curious to inspect the newcomers, and they soon surrounded us talking away at a great rate; they were apparently greatly interested in us and much more so when I had given them some tobacco. This was the first time in my life that I had been amongst a crowd of real live savages in all their war paint and light and airy but varied costumes, and I cannot say I felt quite at home amongst them. However we left them in good-will towards us, and soon were on board again. At day-break the 6th July we left here for Tonga, where we arrived at 11 a.m. Tonga is a small island to the southward of and within a gunshot of the large island of Espiritu Santo. Our party had now been reduced to two, the others having left at the different places we had stopped at. We were cordially invited to spend the time we were to be here by the missionary, and were only too glad to have the opportunity of doing so. We soon went ashore with him, and when we got on the beach, it was apparent that our host had shown great sense in selecting such a place for his home, instead of the stretches of low lying land on the shores of the adjacent island of Santo. The highest point in this island is about 80 ft. above the sea, and the mission had purchased a broad strip of land stretching right across the island from sea to sea, and over the highest point, from which there is a splendid view. The underwood is all cleared, and only the large trees left standing, some of which are very fine. The ground is now covered with fine couch grass, forming altogether quite a charming little park. On the way up to his house, I felt as if something was left out, and could not think what was the matter for some time; however on the approach of some more natives, the fact crossed my mind, that the shaking of hands was dispensed with. The near approach to the house is through a large flower garden tastefully laid out and many English plants were in bloom. The house is about 150 yards from the beach, and I was very glad to be once more in a comfortable room, and was soon refreshed by a nice shower-bath, which had been very ingeniously contrived. There were many things to be seen and admired both in and outside of the house, particularly his large and varied collection of New Hebridean shells, also his albums of dried ferns and mosses. Looking out in front at the flower garden and at the poultry yard behind where there were numbers of fowls and turkeys, one could fancy that we were at home, and in one sense of the word felt quite at home, in fact it would be difficult for one to feel otherwise, our host and his wife doing all they possibly could for us and showing us every kindness. After dinner I went and lay on the springy grass, under the shade of a large hanyan tree, smoking and admiring the magnificent view before me. On the opposite island of Santo, the high range of hills there with their many shadows formed a good background. The little S. S. "Tinganiui" lying at anchor in the narrow passage between the islands, whilst scores of wild pigeons with their beautiful plumage were cooing in the branches overhead. In the evening we went to church, and one could see there what the missionary had done. There were some 40 natives or so at service, many joining in the hymns which were sung in the native language. After service we went to the village, which consisted of some 25 houses, to see a chief who was ill, and a man was pointed out to me who had threatened the missionary, as he only did not want one there. The mosquitoes here are different from most other mosquitoes as they do not sing, so that one is not aware that they are near, until they bite, which they do vigorously. In the morning while at breakfast, the steamer's whistle was blown to hurry us away, and I was compelled to leave our kind friends and once more start on my travels, and had now parted with the last of the missionaries who had gone to the Synod for the time being. We sailed at 7-20 a.m. on

the 7th for Maalo or St. Bartholomew Island, and arrived about a quarter to 9, where we lay to and after delivering the mails went to Aoré Island and lay to there for a short time, then went back again to Maalo. We sailed at 8 a.m. on the 8th for Aobá Island, staying there for a short time, and were off again for a trader's station on the same island; *en route* we passed a trader's place that had been burnt down by the natives after he had left, and I learnt later on that he had been threatened. We anchored off a station for the night, and at 5-30 a.m. on the 9th we sailed for Balhogé, the Church of England missionary's place on Pentecost Island, where after landing over the mails, we left for the island of Ambrym and stayed at Rhanone anchorage a short time. There is a very high volcano on Ambrym not now active, the land here is all volcanic and the sand on the beach quite black. From here we started on our return journey to the southward. Passing by the Island of Api we saw the Union Jack flying, where we had landed the new missionary, showing that all was well. Called again at Tonga where we stopped for the night; the native who had been out gathering ferns with me on my former visit called Billy sent a message to me that he had ferns for me, and on my going ashore for the second time, soon came forward to shake hands and brought me to his house, where he had started a garden, which he had planted with ferns, orchids, crotons, eolias and many other plants. I picked out a few that I wanted, and he seemed much disappointed that I did not take them all, saying, "Why you no take this fellow? Him very good fellow; bye and bye he make plenty good ki-ki" (food). No sooner had I done with him, than another man, pulling me by the sleeve, said to come to his house, where he had all the same plenty good fellow. Fellow is a word frequently used by those who speak a little English signifying either man or woman, animals, plants or goods, as the case may be. On parting I gave Mr. Billy's hand a good squeeze, and judging from the wry expressions on his face, he felt our parting, but I told him it probably would not be our last, as I hoped by-and-by, some time, tomorrow, to see him again. The natives about were amused at the hand shaking and seemed to think it properly done. We arrived at Havanuuh harbour at 1 p.m. on the 12th, when I left the "Trugani" until her return from the south. While here I went for a trip with the missionary in a first rate whale boat to a place called Bow, about 20 miles or more away, and had a very rough time of it *en route*. We were in imminent danger of our lives on one occasion, being out all night to 2-30 a.m. In the morning, with very bad weather, and close to reefs and with an exhausted and sea-sick crew; altogether there were 17 of us including native crew and passengers.

At Bow I had the honour of seeing the foundation timbers laid for a church and the marriage of four native couples on our arrival at the village. After word was given that we were to dine there, all hands turned out and made chase for the fowls, which here could both run and fly remarkably well, as they were accustomed of an evening to fly to the branches of some of the tallest trees to roost; it was very amusing to watch this chase in which men, women and children joined. Over stone walls, helter skelter they went into the bush, after the particular rooster who was doomed, all the fowls of the village joining in the general eburn, while the pigs, which were numerous, sometimes got in the way, but over such obstacles the natives nimbly skipped and soon they returned with the object of their chase, his neck in the meantime having been wrung, many hands made light work and he was soon divested of his gay plumage and into the pot he went. Two nice clean houses were prepared for our use, dozens of nice clean native-made mats having been laid on the floors and stretchers on which we were to sleep. On our way to Bow, part of which was through forest, I killed a large non-venomous snake six feet long. All the snakes in these islands are non-venomous. In this village there was a perfect albino and it did look peculiar amongst the dusks,

the father seemed very proud of the boy and showed great affection for him. On our return journey we stopped at a village called Ebulle 5 miles from Bow. Here we were not as luxuriously accommodated as at Bow, we allest in a large native hut side by side on some mats, the smoke from the embers of a fire, which was in the centre of the room, keeping the mosquitoes away. At one end of the room, on the other side of a sack partition, reposed a native and his family, while round the fire were equatted some half-dozen natives smoking and discussing, I presume, the events of the day. We were very fatigued and when all was quiet I got to sleep, but I had noticed two tom cats on a box immediately behind us with their bristles up and tails curling about looking as if they intended a row, anticipating which I got a few articles placed handy. I was not allowed to enjoy sleep long, for I was soon aroused by an awful mêlée, the cats being engaged in a fierce fight; so great was the squalling etc. that there seemed to me to be at least a dozen cats engaged. This was not to be borne, and we were up in a moment and soon persuaded the cats to leave, after which I had a little sleep and was roused at 4 a.m. by the words "It's time to ho off." After completing my toilet with a coconut shell full of water and brushing my hair in the dark I was ready for early breakfast; when it was finished we resumed our journey to where the boat lay and sailed down to Undine Bay. Here we landed and went up and had breakfast with Mr. and Mrs. Roche, who made us very welcome. After breakfast my friends returned to Havannah Harbor. I was only too glad to have the opportunity of staying and accepted their kind invitation to stay as long as I liked and did so for four days, spending part of the time at the elder Mr. Roche's house and part with his brother who lives on the coffee estate, which he superintends. The view from the house, which is situated some 700 ft. above the sea, is very fine, the large bay stretching away to Severi Point at the south with several islands in view and with a good extent of country covered with tropical vegetation in the foreground forms a pretty scene. What with pigeon shooting, fern gathering and going about through the coffee estate, admiring the many things to be seen there, time flew, though I should much liked to have made a yet longer stay with my kind friends, I had to return on the 19th to Havannah harbor, where I found one of my fellow-passengers who had been away on an expedition to some of the islands had returned and we spent a few hours pleasantly, recounting the experiences that we had in the meantime, which as far as boat expeditions were concerned were somewhat similar and the dangers gone through in his expeditions, were quite equal to, if not worse than my own. One day he inaugurated canoe races, both sailing and paddling, the latter being very amusing, there being great excitement among the natives engaged in the race and their spouses and friends on the shore; the prizes which were arranged for by my friend were gratefully received by the winners. The opportunity of portraying such a novel sight in the islands was not to be lost, and photographs were taken. While preparing for the races, there was an earthquake and the feeling one experienced is difficult to describe, as one did not quite know, whether we were going to fall down or not. I heard since that it was felt at many of the islands and was caused no doubt by that portion of the volcano Yassuer on which our party had been standing having fallen in and blocked up the outlet. Monday, the 28th, was a day of some excitement, as the S.S. "Truganini" was expected and much wished for, as we all expected mails, not having heard for some time from the outside world. For her, she was unusually late, but at last after much waiting and watching she hove in sight and we were soon alongside and on board of her. We soon had to be away again as this busy little steamer had to anchor further up the harbour. On the 29th I left Havannah harbour again northabout with half-a-dozen other passengers, my kind friends of the Mission, some tourists and a missionary for Santo.

I soon had to leave them and stayed again at the island of Tonga, which island had a great attraction for me, it being the richest of those that I had seen and most luxuriant in vegetation. There I spent part of three days and have to thank my host there for his kindness and trouble. He lent me his boat and native crew and I sailed on the 31st July with a good strong breeze for Sakow on the adjacent island of Api ten miles away and stayed the night there in a house the Mission had put up and sailed next morning for Borumba, twenty miles off. There I stayed over a week making some trips about with my host and adding greatly to my collection of curiosities and ferns and having a good opportunity of seeing more of the heathen natives than I had yet had, and was struck with the way in which their gardens were cultivated, the yam vines being carefully trained and the ground kept free from weeds. The heathen natives here were mostly powerful and well made men and were generally occupied at something. Some were building a very fine large canoe some 45 or 50 feet long which was launched while I was there. The lower part of the canoe was in one piece, made of the hollowed trunk of a tree, and the upper consisted of some dozen or more pieces, artistically joined together with plaited coconut fibre, the bows of the canoe being ornamented with various devices. When the tide was out I spent a few hours low and again, on the large coral reef, extending for about a mile along and a quarter of a mile from the shore. Here it was simply beautiful, the colors of the many varieties of coral and of the fish were beyond anything I had ever seen. On one occasion a native shot a fish with his bow and arrow which is their favourite way of getting them. On the 8th of August I started on my final return journey, calling again at Havannah Harbour en route to the south and spending a pleasant Sunday on board H. M. S. "Dart." We called at some of the places that we were at before and had a different experience of the volcano this time, as ashes were falling from it over the ship, the man at the wheel having to hold one hand over his eyes while steering. On Friday, the 15th August, we arrived at Aneityum and spent most of the day ashore part of the time in the forest on the hills, and although I had not sufficient room in my cases for any more ferns I could not resist the temptation of pulling a few. I have heard that there are 120 varieties of ferns in this island alone. In the evening I went on board and transhipped my goods and chattels from the "Truganini" to the A. U. S. N. Company's fine large ship the "Waronga" and sailed for Sydney on Saturday, the 16th, bidding good-bye to the New Hebrides at any rate for the present, but I hope, it will be my luck to have another visit to them later on, having spent an enjoyable time and seen many beautiful, novel and interesting sights.

SOIL AND CLIMATE OF THE NEW HEBRIDES:—THEIR

ANNEXATION ADVOCATED.

Speaking generally of the New Hebrides, many tropical products can be grown there, and ought to pay choosing the locality that would be most favourable to each: coffee, tea, cacao, nutmegs, pepper, vanilla, tobacco, cinchona and bananas would I believe do well. People about to open land there would do well to profit by the experience some have had in Ceylon and not put all their eggs in one basket by planting only one product. The New Hebrides have advantages over many other tropical countries, there being no disease on coffee and having plenty of cheap labour which will be easily obtained, when the laws at present affecting it are made less stringent. Among the many plants etc. that I have seen there, as well as growing in Ceylon showing how similar the climate must be, were beside coconuts, breadfruit which attains a larger size than I have seen in Ceylon, jackfruit, I having come across but one tree of that species and from the wood of which good and lasting furniture can be made, vanilla, cotton, guavas, papaws, very fine oranges, lemons, which attain a large size, vines, castor oil tree, lantana, chillies, beans, brinjals, carrots, turpins, vegetable marrows, onions, cabbages, roses, eucharis lilies,

agerstium and iluk grass, the two last being troublesome weeds, particularly the iluk grass, the roots of which spread rapidly. Laud can be easily and cheaply purchased either from the natives or from early settlers who have obtained large tracts. It can also be leased from an Austrian Co. The British are at present handicapped to a certain degree, as the French are allowed by their Government to purchase land for rifles and ammunition while we of necessity must pay in cash or trade. Many in Australia interested in these islands are now urging the authorities either to allow us the same advantages as the French or to get them to prevent their subjects selling firearms which would place us on an equal footing. The soil on most of the islands is very rich, chiefly volcanic, but in Anicityum it is evident that no volcano has been active for many years, as there is a deep layer of surface soil composed of vegetable mould, formed by decayed leaves and timber. In some islands particularly the northern ones the climate is hot but pleasant; climates can be got on high elevations, even on Santo, the most northerly. There seemed to me to be a marked difference between the places north and south of Vila, Sandwich Island. Those south of Vila being colder, many of the missionaries and their children got fever. In some cases this can be accounted for by the fact that the houses are built on low ground and surrounded almost by forest. Some on the other hand who have been able to obtain favourable situation from the natives and particularly those living in the southernmost islands do not complain of the climate. In proportion as estates are opened and the land cleared so will fever disappear, as in most countries covered with forest and dense vegetation.

There are two seasons: summer or the wet and hot season from November to April, and winter or the dry and cool season for the rest of the year. The driest months being July and August and those with the largest rainfall February and March. The temperature at Anicityum 3-30 p.m. on 25th June was 77° in the shade. At Huvaush harbour further north in July at 6-40 a.m. it was 63°, at 12-30 p.m. 74°, and at 3-15 p.m. 76. I was told that the highest known temperature there in the shade was 92°. At the island of Apii further north still it was much higher, owing probably to the house being so closed in. The temperature there at 8 a.m. being 74° and in the afternoon 85°. Temperatures can be had in the islands from 63° in the morning at Anicityum in the south to 76° or 78° in the afternoon and in the north at Santo on the sea coast from 73° or 75° in the morning to 90 or 95 in the afternoon. At a high elevation on Santo where the mountains go to 4,000 or 5,000 feet the same temperature would be found as at Anicityum. From the records that I could get it appears that the rainfall on the different islands is from 70 to 120 inches. Hurricanes are to be feared; some years they occur and some they do not, while sometimes some islands get them and others do not. I have heard they do a lot of damage principally to coconuts and vegetation on the sea coast, yet the coffee I have seen shortly after a hurricane which I experienced did not seem to have been affected by it, owing no doubt to the fact that coffee is planted under the shade of and sheltered by forest trees and not in the open as in Ceylon.

The population of the islands is about 60,000 in some islands, there being but few inhabitants and they are decreasing, the probable causes of this being the introduction of diseases and epidemics, infanticide and tribal wars, exportation of labour to other countries and last though not least inaction and laziness among some of them. That inaction and laziness produce enervation and degradation in a race is well known, and examples in other countries are not wanting. Were the British to settle there and open up estates which I feel sure will happen when the islands are better known and that before long, as many people are now going to see the islands, since steam communication has been established, the natives would be employed at regular work and their present condition would thereby be improved in many ways. Most of the heathen that I have seen are a powerful looking well built people,

and I do not believe they will ever become extinct as they can and will work. Large numbers of them have been taken to Queensland every year for many years, New Caledonia and other places, there having been perhaps as many as a dozen vessels engaged in that trade up to 1891. This traffic I am glad to be able to say has been stopped as far as Queensland is concerned, and I trust the deportation of these islanders will entirely cease before long. I say this in their own interests and also of those who will open up land there in the near future.

Wild animals there are none, but there are snakes, however, they are non-venomous. Many species of pigeons, bush turkeys, jungle-fowl and some duck.

Toures of land: the best method for securing a title to land at present is to make out a deed defining the land bought and from whom, as there may be many people having a share in the land. Getting the acquiescence of the chiefs and natives in the vicinity, witnessed by a missionary if there should be one and where near and the chief and some of the natives about getting the deed registered by the French in Noumea and by the British High Commissioner for the Pacific in Fiji. Such a deed would be recognised were either the British or French to annex and would not be disputed by the natives. I have no hesitation in advising people to buy land there now and were the land occupied at once all disputes would be obviated. Neither England or France has annexed the islands. They are looked after by a joint commission of British and French man-of-war. A special Commissioner or one of each nation meantime is required to live in the group who will have power to register titles and agreements between settlers and their labourers and to enforce same as well as power to settle disputes. The necessity for this cannot be too strongly brought before the authorities and the sooner the better to avoid future complications. There are I dare say 500 acres already planted up with coffee in different parts of the islands some 10 years old, and the coffee I have seen is very fine and I do not think can be surpassed in any part of the world. In conclusion I would suggest to those in Australia and those who have come for a trip to Australia who would wish to spend a holiday away from the cares of business, to take a run down to these islands, lasting a month and costing £25 return ticket from Melbourne, Australia will there see something new and unlike anything they have seen in Australia in point of scenery. It is a rich and fertile country and I feel sure when better known that this valuable group of islands will be opened up. I have heard it said, "We don't want annexation," and I have seen it written. If a British minister in a weak moment consent to the handing over of this group, Australasia will assuredly when the time comes take steps to regain her heritage in the Western Pacific. But meantime the natives will dwindle away, and then of what use will the islands be? It may be presumptions of me but I say if of no use. We have not yet got machinery that will plant tea and coffee. Action should be taken at once. Why not petition the Home Authorities to send a commission there and they would then know their value to Australia and the necessity for annexation. Leaving that aside, how can we think of giving up what our missionaries have gained for us by their great labour and trouble, having had to bear many hardships and frequently been in danger of their lives? indeed several have been killed while doing their duty.

The subject would demand to have its claims and merits put forward by a more able exponent than I am, but I trust this will have created some interest amongst those here; and were I to know that it had done so in the smallest degree I shall feel fully repaid.

NOTES ON PRODUCE AND FINANCE.

CO-OPERATION REGARDING LABOUR IN ASSAM, &c.—We are glad to note that at a largely-attended meeting of the General Committee of the Indian Tea Districts' Tea Association, held this week, a resolution was unanimously passed in favour of supporting the move.

ment recently in Calcutta for the formation of a central labour organisation on co-operative principles to control the recruiting of coolies. Co-operation on this important subject cannot fail to strengthen the position of tea proprietors in Assam.

MORE LIGHT.—Mincing Lane has been amused at a paragraph which appeared in the *Daily Chronicle*, a few days since, to the effect that a tea-tasting committee of the guardians of Islington Workhouse had made a new discovery in tea-tasting. The paragraph was as follows:—"Something like thirty samples of black tea had been sent in by different firms, who sought to obtain a contract for 7,300 lb. of tea in bond at 10d. As usual a cup of tea was made from each sample, and the committee then proceeded with the operation of tasting. It is customary to allow the cups to stand for five or six minutes, but on this occasion, owing to an accident, they were left standing for twenty minutes. When the committee examined them, to their great surprise, they found that the tea in about a dozen of the cups had undergone an extraordinary change. Instead of being quite clear it had the appearance of cocoa; and, curiously enough, the change did not take place until the cups had been standing for more than fifteen minutes. Among the samples that had undergone the change were one or two which had been looked upon as the best teas. The samples will, it is understood, be submitted to analysis."

TEA TASTERS WANTED.—If this "creaming down" of tea scares the tea-tasting committee of the workhouse it is high time that parochial authorities who buy tea on a large scale, employed the services of an expert on the premises. In the absence of an adult, a youth who understood the business would be useful. As the *Daily Chronicle* says:—"It is a common experience that all good teas from India and Ceylon 'cream down,' as the technical phrase is, when cold, and present the appearance which aroused the suspicious of the guardians. If they do not, the samples are at once put on one side as being inferior. The change is wrought by the atmosphere coming in contact with the tannin developed by the process of infusion, and it is highly probable that the sample which was approved was greatly inferior to many of those rejected. In large contracts of this description the services of an experienced taster might with advantage be requisitioned."

THE DECAY OF THE CHINA TEA TRADE.—In some districts of China the tea-growers take such a gloomy view of their prospects that they are turning their attention to other things. A Foochow paper says:—"Two tea-growers are, we understand, planting poppies in the place of tea in the lower ranges of their tea plantations. If they meet with success, others will follow their example and give up tea altogether." For this China has only herself to thank. By heavy export duty and local taxes and "squeezees" innumerable, she has done her best to kill the trade which for so long gave her a proud pre-eminence among the countries of the world.

LAST WEEK'S SALES.—There has again been a falling-off in the supply of Indian tea, says the *Produce Markets Review*, the quantities offered being 28,000 packages, against 31,000 in the preceding week. Although the demand generally is by no means active, there are evidences of an improved enquiry, more particularly for all good descriptions. For medium and fine sorts the demand has been decidedly better, with a further upward tendency in values, and unless a larger supply of these descriptions is forthcoming, higher prices in the near future are not improbable. No material change has taken place in the lower sorts, although buyers find it difficult to follow previous purchases, this being more particularly the case in whole leaf kinds of good useful qualities, which are not so plentifully offered just now. On the other hand, common and undesirable teas are dull of sale, and have passed at irregular rates. At the public sale 25,654 packages were catalogued, and about 3,000 withdrawn, most of which have since found buyers. The following are the figures issued for the past month compared with January last year:—The imports were 13,600,000 lb. and 13,300,000 lb. respectively, while deliveries were about 600,000 lb.

smaller, or 9,967,600 lb. against 10,570,000 lb. The stock, on the other hand, shows an increase of 10,000,000 lb. the quantity being 49,000,000 lb. as compared with 39,000,000 lb. in the previous year. This increase in the stock almost exactly corresponds with the difference in the imports from June 1st to January 31st in each year, which amounted to 91,900,000 lb. and 81,200,000 lb. respectively. Ceylon teas have been strongly competed for, and a general but not very extensive rise in prices has again taken place. The improvement has been, perhaps, most marked in medium Pekoes, for which the competition is particularly keen, and which are about $\frac{1}{2}$ d dearer. Common grades are also in demand and show about $\frac{1}{2}$ d rise on the prices of a fortnight since. The quality of the teas has shown a slight improvement, but has not yet reached a satisfactory level. Reports as to the quantity of tea coming forward are somewhat contradictory, but it may be taken for granted that it will exceed last year by some millions of pounds, all of which will be required if the present rate of increase in the consumption is maintained. Some private advices, however, report the quantity immediately available as somewhat less than expected.

THE BOARD OF TRADE RETURNS AND PRODUCE.—The Board of Trade Returns are again unsatisfactory, inasmuch as with an increased value of imports the value of the exports has decreased. The latter feature is not, however, so marked as in November and December of last year. The imports amount to £38,485,244, an increase of £4,744,162, or 14 per cent.; and the exports of British and Irish produce to £19,146,701, a decrease of £687,611, or about $\frac{1}{2}$ per cent. Arrivals of tea were heavy, particularly from India and Ceylon, but China receipts were also large. The total quantity of tea imported in January this year was 24,678,797 lb.; value, £1,083,098; against 21,350,948 lb.; value £947,804, in January, 1891. Of refined sugar, Germany and Holland have sent more, but France only sent 83,280 cwt. compared with 209,987 cwt. This article has gone up in price, which, perhaps, accounts for the larger imports, £72,000 alone of the increased value being due to this cause. With the exception of Holland the best-producing countries have sent less raw sugar, but some producing countries have in the aggregate sent more. This article too has gone up in price. Of the articles cleared for consumption, tea is below the total of last year, but is considerably in excess of January, 1890: the check would appear to be only temporary.

BONNED PRODUCE.—The B Bill of Entry shows that on the last day of January the quantity of tea remaining in the Customs and Excise warehouses of the United Kingdom was 111,066,449 lb., against 100,646,624 lb. and 115,373,806 lb.; of cocoa, 11,317,755 lb., against 12,785,781 lb. and 11,262,786 lb.; coffee, 118,277 cwt., against 122,494 cwt.

COFFEE ADULTERATION.—Coffee planters must feel disgusted at the shameful adulteration of coffee. In vain public analysts point out the adulteration, but it is quite easy for the vendors to evade the law. At a recent meeting of St. Luke's Vestry, the analyst said:—"In the case of the coffee that was found to contain 50 per cent. of chicory no prosecution was undertaken, because the packet was labelled 'a mixture'—this one of the magistrates at Worship Street having held to be a good defence in a previous case. In another case where 85 per cent. of chicory was present, and there was no label announcing 'a mixture,' the Vestry did prosecute. The vendor, however, swore that he verbally stated to the purchaser that the article was a mixture, and the inspector swore in equally positive terms that no such statement was made. The magistrate believed the vendor, and dismissed the summons. Hence, added the analyst, it appears that a dealer may sell any amount of chicory to a buyer who asks for coffee without even pretending to label it. Certainly the taster has a worse time than the others. The law protects the purchaser from having his beer or spirits watered, but wins't take at any amount of coffee adulteration."

tion." At the Durham County Council's annual meeting, held last week, the analyst reported that he had given special attention to coffee mixtures, in order to check, if possible, the practice of vending mixtures containing an undue proportion of chicory at little less than the price of good coffee. In one case, which had not yet been heard, the chicory amounted to 83 per cent.

LONDON PRODUCE CLEARING-HOUSE.—The report of the directors for the year ended Dec. 31, 1891, states: "The accounts, after making provision for bad and doubtful debts, and including £2,346, 4s. 10d. brought forward on Jan. 1 last show a gross profit of £20,652 16s. 11d. After deducting current expenses, there remains a balance of £10,319 1s. 6d. Out of this sum the directors propose to pay a dividend at the rate of 3s. 3d. per share on the ordinary share capital, and £2 1s. 8d. per share on the founders' shares, which will absorb £8,125 0s. 2d. and to carry forward the balance, £2,194 1s. 4d. to new account. The general depression and want of enterprise which have marked the past year have made themselves felt in the company's business, the total number of contracts registered having been smaller than in the previous twelve months. The dealings in coffee continue to be unfavourably affected by restricted supplies, and also by forward prices remaining below those for immediate delivery, while it is only during the last three months that the sugar market has shown any activity. The contracts in China tea have been nearly equal to those of the previous year, notwithstanding a considerable contraction at the close, which contraction has, however, been counter balanced by the increased dealings in Indian tea. In grain the year's transactions have been extremely limited and disappointing; but with the revision which has just been made in the company's rules it is hoped that the new form of contract will attract business. The only additional commodity introduced during the past year has been silver bullion, for which a market is being sought through the Clearing-house, in conjunction with a system of storage and warrants, which cannot fail, it is thought, to benefit London trade in the metal."—*Il. and C. Mail*, Feb. 12th.

CEYLON PLANTERS' AMERICAN TEA COMPANY.

A general meeting of the shareholders in the Ceylon Planters' American Tea Co., Ltd., in liquidation, was held this afternoon at the registered office of the Co., 9, Queen Street, Fort, Colombo, "to consider (in compliance with sub-sections 10, 11, and 12 of clause 107 of the Joint Stock Companies Ordinance, No. 4 of 1861) the accounts of the liquidators of the winding up of the Company, and such further business in connection therewith as may be brought before the meeting."

The Hon. W. W. MITCHELL occupied the chair, and the others present were the Hon. J. J. Grinlinton, Mr. W. H. Davies, and Mr. J. F. Headrick. Mr. Mitchell held proxies from Messrs. H. Whitham, Jas. Westland, J. F. Millington and W. Morton Smith. The notice calling the meeting and the minutes of the previous meeting having been read,

Mr. HEADRICK read the following report by Mr. S. T. Richmond, auditor:—"On examination I find the accounts in order, and that in accordance with resolution of the shareholders on 9th April 1891 confirmed by the meeting of 28th May 1891, the assets of the Coy. have been transferred to the Ceylon Planters' Tea Company of New York except the cash in hand, of which all that may remain should be sent to the Company on final closing of the accounts after they are confirmed by the shareholders. The statement of the share scrip received from the New York Company, and the issue of same, shows, that the scrip in the Ceylon Company for 52 shares has not been received from shareholders and consequently the

scrip in return for these shares has not come from New York. The expenditure of the capital is shown to be—less as per accounts of 30th June 1890 £29,036-95; expenditure since 30th June 1890 (including cost of liquidation) £10,853-64; remittances to New York £29,487-17; amounts due at New York (including value of furniture) £15,186-32; cash in hand £355-62—84,980, less for transfer fees £20—£84,960."

It was stated that Mr. Richmond had been appointed by the liquidators, and thereupon the meeting passed the following resolution which was proposed by the CHAIRMAN and seconded by Mr. DAVIES:—"That this meeting confirms the appointment of Mr. S. T. Richmond to inspect the accounts."

Afterwards it was resolved on the motion of Mr. DAVIES, seconded by the CHAIRMAN:—"Having received and considered the accounts of the liquidators this meeting is of opinion that the affairs of the Company have been fairly wound up."

Mr. DAVIES asked if any information had been received from the New York Company as to the progress that had been made during the past year.

The CHAIRMAN in answer read from a letter dated 21st January received from New York:—"We now wish you to purchase and forward to us lots of our Standard grades, of orange or flowery pekoe, pekoe and souchong. We have had no teas more satisfactory or taster arrived in better condition, than those forwarded to us by you in January 1890, and we desire that you will blend them as you did then, pack them in convenient sized packages and if possible send by one ship. The cases should be marked as directed in our letter to you of the 4th September 1891. Unless you hear from us to the contrary you may ship us monthly lots of Uva and Nona and Ranta. We would also like to have you send us with each shipment, high grown plantation packed in barrels and native or garden parchment clean coffee. Mr. Farr, our treasurer, will advise you to draw against the credit now in your possession. By mail please send us Clarke's series of photographs and say four dozen additional representative of Ceylon native character, architecture and scenery and copies of those relating to tea taken last year expressly for us. Mr. May, the president, wishes you to sound a note of warning to the planters of Ceylon, and to urge upon them the absolute necessity for them to maintain the highest standard of quality. If this is not done their business with America will be a total failure. Our annual meeting takes place in May. Our sales for 1891 were 56,818 lb. and during that year we distributed free 3,034 lb., in small samples." Mr. Mitchell remarked that the Company had been buying supplies almost wholly in London during the past year and they had only now reverted to purchasing in Ceylon which he hoped they would continue to do. They had telegraphed for native servants, and he was in communication with the Rev. Mr. Thomas of the Tamil Cooiy Mission to procure a Tamil man and his wife to send over. All that looked like business, and although the progress had been slow it was evidently sure. He could only express the hope that the interests of the Company would benefit very greatly as they hoped the interests of Ceylon generally would benefit by the mission of Mr. Grinlinton to Chicago. (Hear, hear.) The attention of the people in America would, of course, be largely centered upon tea at that Exhibition, and it was to be hoped that the demand for the tea that this Company supplied would go on increasing.

The proceedings then terminated,

A JAPANESE SULPHUR MINE.

A writer in the *Japan Mail*, of Yokobama, describes a visit to a sulphur mine in the northern part of the main island. The works are situated on a platform made in a gorge partly by hand and partly by a landslip, and from the back a road goes up to the *solfataras*. On each side are high hills well wooded, save where landslips have occurred. They possess a bath, deliciously warm, containing sulphur in suspension and iron and alum in solution. The sulphur is melted by super-heated steam. About a mile up the gorge are the springs which supply the baths at the works, and also a bathing establishment in another valley some miles away, and another spring is used by the miners to cook their rice. All are boiling when they issue, but unless enclosed in covered pipes they cool rapidly and deposit fine "flowers of sulphur," which is collected and sold for local consumption. Leaving the springs, the sulphur region proper is entered which is almost at the top of the gorge, or head of the valley. Before coming into the hands of the present proprietors, the *solfatara* was worked on Government account, and one of the old workings is very curious. It is a small gallery with a hot ceiling, and exudes very beautiful needle-shaped crystals of pure sulphur, boiling hot, and transparent when first gathered, but they soon become opaque and change into small octahedral crystals that will not bear much pressure, but crumble to the touch—showing that the sulphur has been deposited at fusing heat. Arriving at the head of the stream the ascent of the crater begins. There is a toboggan slide of 720 ft. from the crest of the crater down the steep cone to the upper workings. The ascent is neither safe nor easy. A miner went in front with a pick to cut steps, and the clouds were entered about half-way up. At the bottom of the crater are very rich moulds of sulphur ore in inexhaustible quantities. The workings give off fumes and gas, and great care is needed by the workmen. The places seemed much like that described in one of Sinbad's voyages—no life, no vegetation, no water, only mud and sulphur. It is on record that 315 years ago the crater exploded like Bandaian and did great damage. The path down the gap then made in the crater is a difficult one, overhanging rocks threatening at every step, the path entirely obliterated, and the chasms left by the torrent being both steep and dangerous. Above the neighbouring town of Numajiri there is a sulphur factory on the old Japanese principle of smelting in an open boiler and refining in a close cylinder furnace. It was not at work, but must be a most wasteful method, and hurtful from the fumes given off. The deposits are enormous, and must amount to millions of tons. The proprietors profess to turn out on article equal to the "roll" sulphur of commerce. In the sulphur regions there is no sign of life, vegetable or animal, but the cone and descent are well wooded, and rare plants and flowers flourish in profusion. These, however, become stunted as one descends into the crater, and on the mud plain there is not a vestige of verdure. There are, of course, no fish in the rivers. —*Chemical Trade Journal*.

NUX VOMICA LEAVES PARASITIC, WHILE PARASITES GROWING ON THE TREE ARE NOT.—Our correspondent "T." will be interested in the following extract from the *S. I. Observer*, unless indeed he has received the information direct from Mr. Hooper. That the parasitic guest should, in imbibing poisonous juice from its host have power to eliminate the poisonous principles, is surely

Curious:—

It will interest our plating readers to know that the leaves of the *Nux Vomica* are to some extent poisonous. In November 1820 Mr. J. Cameron of Bangalore enquired if fresh *Nux Vomica* leaves were poisonous informing Mr. Hooper the Government Quinologist that a gentleman residing near him had lost three horses from, it was supposed, their eating leaves of this tree. Another case was that of a cow belonging to Sir Oliver St. John dying under suspicious circumstances, and *Nux Vomica* trees were growing in the compound where she was in the habit of grazing. The cow had convulsions, bled at the mouth and nostrils, and only lived a short time from the commencement of the attack. The poisonous nature of the leaves Mr. Hooper tells us has never to his knowledge been investigated, so he considered this a sufficient reason for prosecuting an inquiry into the subject, and we learn that an analysis of the leaves resulted in the separation of an alkaloid having the properties of brucine, and amounting to 0.35 per cent. Brucine is associated with strychnine in the seeds of the *Nux Vomica*, as well as in the wood and bark, and has the same physiological effects as strychnine in including well-marked tetanic symptoms. The leaves of the *Nux Vomica* therefore Mr. Hooper says: "Taken in sufficient quantity, would produce poisonous results and precautions should be taken in keeping cattle from feeding on them."

Another question of interest has also been recently investigated in connexion with the poisonous nature of the vegetable parasites growing on the *Nux Vomica*: "It is recorded in the Pharmacopœia of India that species of *Viscum* and *Loranthus* growing on this tree become just as poisonous as the tree itself, and that in the leaves of one species the *Viscum Monoicum* the two alkaloids, strychnine and brucine were detected. These statements have been copied into other works without experimental confirmation, and the small sample obtained from the Ganjam district for analysis by Mr. Hooper showed that the alkaloid present was neither strychnine or brucine. The leaves contained a peculiar tannic acid similar to that found in other mistletoe, and a resin soluble in ether and alcohol, striking a blood red colour with strong sulphuric acid, and the chemical constituents are said to be altogether different to those found in the leaves of the *Nux Vomica*, "and this fact" Mr. Hooper says "goes to disprove the theory that parasites partake of the properties of their hosts." In confirmation of this M. Cbatin recently contributed to the Paris Academy of Sciences a note on the biology of parasites in which he asserts that the tannin of the mistletoe is not identical with that of the Oak on which it grows; that the *Loranthus* on the *Nux Vomica* does not contain a trace of either strychnine or brucine and that the *Balanophora* parasite on *Cinchona Calisaya* does not contain any of the alkaloids of *Cinchona* bark. "It is evident therefore" says Mr. Hooper "that the sap absorbed from the host plant must be modified by the parasite to form its own peculiar products."

ANALYSIS OF TEA IN PARIS.—The *Chemist and Druggist* states that at a meeting of the Paris Society of Pharmacy on February 3, Mr. Bürker made some remarks on the analysis of tea. With his usual interest in all that appertains to the chemistry of articles of alimentation in daily use, the affable vice-president has gone into the matter with various tea-merchants, besides studying the latest works on the subject. He gave the meeting a digest of these with his own observations thereupon. He thought it pretty well established that the commercial value of black tea is in direct proportions to the amount of tannin contained in the sample analysed. In the case of green tea, this test does not answer, the question to be studied being rather the amount of tannin. These remarks aroused evident interest, and a lively conversational discussion followed. Some five or six members raised various points, but M. Bürker apparently succeeded in satisfying his interlocutors.

THE GIANT BAMBOO IN FLOWER.

Dr. Trimen, Director of the Royal Botanical Gardens of Ceylon, having seen our notice of some stalks of the "giant bamboo" having flowered at Abbotsford, asked for specimens, as he had never seen the inflorescence in its fresh state. We accordingly, before returning from a recent visit to the estate, had specimens despatched. We expressed some doubt as to the flowering being quite normal, because only a few stems out of probably one hundred in a dense clump had blossomed. But from Dr. Trimen's report which we append, it will be seen that the flowers are quite natural:—

"Peradeniya, Feb. 26th.

"The specimens of Giant Bamboo reached me yesterday afternoon. There is nothing abnormal about them; they are the natural flowers, and I have examined them with much interest, as I have never before seen them in a fresh state. Our numerous plants at Peradeniya were all derived by division of one received from the Calcutta Gardens in 1856 and still growing here; but none have ever shown any disposition to flower. I am told, however, that about five years back a clump at Nawalapitiya produced flowers, but I did not get an opportunity of seeing it.

"There is some difficulty in ascertaining the native country of this fine bamboo, *Dendrocalamus giganteus*. Wallich obtained the original plant in the Calcutta Garden from Penang, and Kurz states that it grows only at Malacca and adjacent islands. Munro, the monographer of the bamboos, gives also Tonasserim, on the authority of Dr. Brandis, but Kurz says this is incorrect. This latter botanist has however a Burmese species, which he calls *Dendrocalamus Brandisii*, 'common in tropical forests of Pegu and Mataban up to 3,500 ft.,' which is probably the same and our plant.

"In the Calcutta Garden, where it was introduced in 1831, it did not flower till 1861, and the plant though weakened did not die; we may hope therefore that this is not one of those kinds which succumb to the effort of flowering. It will be most interesting to see if the Abbotsford plant ripens seed, and I hope it will be carefully watched and all the seed sowed."

We are very glad, indeed, to be the means of enabling Dr. Trimen to see and examine fresh blossoms of a very interesting plant. We have always regarded Burma as the habitat of this grandest of the bamboos, the late Mr. John Armitage having reported after a visit to the rice region of Pegu that there sections of the stems were used as grain measures and vessels for carrying water. In Darjiling we saw sections of a closely allied species, *Dendrocalamus Hamiltoni* (which is also grown on Abbotsford, from seed sent by Mr. Gamio), employed by the Bhooteas to carry milk and butter to market, and also for holding supplies of the mild beer which many of them imbibe made from crushed grains of kurakkan with water poured on it and allowed to ferment in the bamboo sections, which the beer-drinkers carry slung over their necks. We got plants of the giant bamboo from Peradeniya about the middle of 1874; so that the stems which have flowered on the banks of the Dimbulandaya at an elevation of 4,460 feet above sea level were between 17 and 18 years of age. At the elevation mentioned the growth and size of stem are quite equal to what can be seen at Peradeniya or in the Pavilion grounds at Kandy; while at an altitude of 5,200 feet on the summit of "Knock Ferrol," the height and circumference of the stems are not very greatly diminished. Split, seasoned and properly prepared, stems of the giant bamboo have proved useful as water spouts and as substitutes for tiles,—tared in this latter case. Of course they could be employed for a variety of structural purposes, and at Peradeniya they are largely used as

flower-pots. It may be interesting to state that sections of the stems, well seasoned, and the outside siliceous covering well cleaned and polished, are favourite substitutes for canvas with lady artists. We prize very much a section on which a lady visitor to Abbotsford painted two of the most prominent of our flowers,—strong contrasts in form and colour,—the snow-white "lily of the Nile" arm and the orange and scarlet "hot poker." A large stem was cut down during our recent visit to meet requisitions from lady amateurs. The clump which has blossomed is one of two which flank a pretty bridge, and up through the centre of one, a blue gum tree grows and flourishes. specimens growing in a ravine and around a lakelet are magnificent in growth and size of stems, while the curving downwards of the feathery foliage at the tall summit branches of the groups has an exquisitely beautiful effect. In Java, where the prevalence of earthquakes renders bamboo houses a necessity, the life of such a building is calculated at twelve years. This is surely an encouragement to use giant or other bamboos for estate lines, cattle sheds and out-houses. Indeed we see nothing impossible in a factory and drying house of giant bamboo.

ARE LARGE OR SMALL HOLDINGS DESIRABLE?

MILDURA SCHEME—SMALL FARMS—PERPETUAL STALL-FEEDING OF CATTLE—NECESSITY OF CONSTANT LABOUR—WORKING FOR HIRE—HARVEST TIME—TENDENCY OF FARMERS TO IDLE—PIECE OR TASK WORK—FURLONGS—MARKET GARDENING—VALUE OF LAND—PECULIARITIES OF MILDURA—PROFITABLE INVESTMENT—EXCESSIVE POPULATION AND SUBDIVISION OF PROPERTY.

Melbourne, Jan. 26th, 1892.

With reference to Mildura or any other similar project of small holdings with "intense culture" I think a few notes taken from a book entitled "A Plea for Peasant Proprietors" by W. T. Thorston, O.B., would be of interest. He says:—"However, since political economy was raised by Adam Smith to the dignity of a science, its British professors have been almost unanimously of opinion that small farms are incompatible with the prosperity either of agriculture or of agricultural labourers. Land, they assert, cannot be properly cultivated unless it be held in large quantities by men of capital, nor can its cultivators be in a satisfactory condition unless they be hired servants, and chiefly independent for subsistence on the wages they receive. The eminent men by whom this notion has been promulgated have supported it by many ingenious and plausible arguments; nor has their advocacy been confined to theoretical reasoning. They have ventured to appeal to experience and observation, and have been able to point to several facts, which, at first sight, and until carefully examined, seem to justify their views." He goes on to show that these facts were:—the undeniable progress in agriculture, arrangement of land, and regular labour to those whose ancestors had been deprived of their lands. Then the produce of small farms may preserve its occupier and his family from downright starvation, but it will prevent him from accumulating stock, this again will rot him of the help of animals in the work of the farm. Thou the same individual has to do everything himself—instead of benefiting by division of labour and the skill of specialist experts in the different lines. Then there is the temptation of idleness; also the habit or necessity of going to market for petty sales, thus not only wasting time but being exposed to temptation of dissipation, extravagance &c. Also periods of no work or slack work would be a source of temptation.

Well the Flemish calculation of holdings gave rise to the British election party cry of "Three acres and a cow."

There they have found that 10 or 12 acres should maintain 4 or 5 cows. This may sound astonishing but it is notorious in the Waas country. Then our author describes the absence of the coloured cattle in the fields and describes the perpetual stall-feeding of the cattle which produces better beef and an enormous increase in manure. It may look inhuman and may in time breed disease, as the method of absolute imprisonment does not appear natural. That however is long ago exploded. In Ceylon where cattle were never allowed out they enjoyed better health, and this method cheapened the manure immensely. To return to our author:—"Combination enables small farmers to construct expensive works for irrigation." Then again. But of all the charges brought against small farmers the most amazing is that which represents them as slothful, so diametrically is it opposed to truth, which literally leaps into the eyes of all who are willing to look in the right direction small farmers (such of them, that is, as are either owners or lease holders of their farms; and it must be distinctly understood that this vindication is intended to apply to no others) are not only not generally indolent, but their most distinguishing characteristic is ardent, constant, nay almost excessive, industry. Circumstances may no doubt be imagined in which it would be impossible for them to be uninterruptedly employed. If in any district all the farms were of the same size, and if that size were insufficient to occupy the entire labour of one man, the occupiers would sometimes be without work at home, and would be unable to procure it elsewhere." This is one of the most serious drawbacks to Mildura, that is to say, if the fruit growers are dependant on their labour. And why not? In such a colony the able bodied men should be constantly employed or assuredly the evils mentioned above that spring from idleness will arise. Though not in pocket set in health and morals, constant labour (though light) is an absolute necessity. Of course if occupants have literary resources, or professional acquirements that can be made use of in slack times than it will be all the better. But still the fact that the holding will be generally about the same size, the products of the same character, and the periods of work and slackness general throughout the colony, the fact will tend to rob the colony of the advantages of constant outside work. Of course there will be many to whom the idea of labouring for others will be utterly repugnant but I am referring to the poor man. Be he gentleman or not, in a colony like Mildura there will never be any disgrace in working for a neighbour for hire. Let the colonists realize this, let them thoroughly consider if it be not better to keep out the ordinary hired servant with his unions and club and strikes, and let all help—let there be none idle. Mildura should never be dependant on the working man. Harvest time will require special assistance, but extra efforts and mutual help on the part of the colonists will almost be sufficient to cope with the special needs. There will be always a mustering of harvest hands from the town centres, when the railway is made, who hope to get employment, just as in the hop-fields of Kent the owners have the poor of London off-ripping themselves in large numbers for present healthful work. This influx, if it be necessary, will entail extra sanitary and police precautions. Mr. Thornton continues:—"But when small farms are defended it is of course understood either that the smallest is sufficiently large to keep its tenant in full work, or that, if any are below that size a proportionate number are above it, unless therefore it be supposed that small farms have a tendency to decrease in size the apprehension that small farmer must necessarily be occasionally idle from absolute deficiency of work may be at once dismissed.

"It is further asserted, however, that the small farmer even when he has work to do, will be apt to shirk it. He is subject to no compulsion. No one can forbid his sitting down as soon as he is tired, or taking a holiday whenever he feels inclined; and it is presumed that he will not fail to abuse this liberty. But although he is exempt from the same compulsion,

he is stimulated to exertion by influences much stronger than any that affect the hired labourer. The latter must not indeed openly dawdle about his business or he may be dismissed; but provided he works hard enough to content his master he is himself content and aims at nothing more."

Mr. Thornton proceeds to argue that the great stimulant to the hired servant is to pay him by "piece work," or as in Ceylon, you call it "task work." (The Tamils call it *'antrap vaele.*) Ceylon planters know how that puts life into coolies. The coolies can do work with a will when it is a case of knocking off work: "*Kanikmoodinjappulay.*" Thus a hired servant is stimulated to work first by fear of dismissal, secondly and still more strongly by piece-work, but this work is of less value than work on his own land. He will not deliberately waste his own time on his own land in working unprofitably. In Zurich where the holdings are small the industry is simply marvellous. Adam Smith says:—"A small proprietor who knows every part of his little territory, who views it with all the affection, which property, especially small property, naturally inspires, and who on that account takes pleasure, not only in cultivating, but in adorning, it is generally of all improvers the most industrious, the most intelligent and the most successful," and Mr. Thornton adds "the most enterprising." In this light does not Mildura compare favourably with Ceylon? Has it not been the great stumbling-block and rock of offence the pernicious greed that led to large acreages which was bred in the unhealthy atmosphere of speculation. But in Ceylon and India, the exotic European is greatly to be excused. All these years the struggle, the end of the struggle, is to be able to "go home." That is almost if not quite hopeless now to the great majority. How many have, how many could, how many will ever clear out? It is not a climate for Europeans, therefore salaries or profits should be on such a scale that frequent furloughs and a speedy retirement should be easily possible. But, alas! the pay of educated planters, the profit of men who were once capitalists, the returns of most of the merchants: men in other countries would be simply astounded when they learned for what a small pittance Englishmen endured exile, loneliness, deprivation of the pleasures of a cultured life, and from amusements, and from good food, and all the concomitants of modern life among white people. And the future is blacker. Then how could he who it is impossible to work, think of small holdings. The thing is out of the question in Ceylon, but not so here. It is not only in Mildura or any such like scheme. But near Melbourne where the rains are sufficient and the market is near—market gardening is a splendid employment. It is true Chinamen are the chief market gardeners of Australia. Well, as one's business increased it would be perfectly possible to employ a Chinaman or even our old friend Kamasamy—but this is the best line to take up. I could give you particulars. In the manual published by Birchnell, Barridge, and Porter, I find a great deal of interesting matter.

"Ten acres can be bought for £150; £1 deposit per acre and balance in monthly, quarterly, half yearly, or yearly payments extending to, 5, 8, and 10 years which is little more than an ordinary rental. "Tomatoes grown in a practical way will produce at least £150 per acre after paying all expenses. Robert sometimes gives £250 per acre as it comes early in the season. Strawberries is also a very profitable product, small holders can go in for poultry-breeding, fruit-growing vegetable-growing, perfume plants and trees, flowers, nurseries, dairying and general cropping. There is no mono culture here and variety enough. Sand with water available for irrigation may be had. I must call on the firm whose pamphlet I have been quoting and get more particulars. Many say Mildura is too far away, and too much money is required for the land which makes it hard work to recover the interest and capital. There is land to be had near Melbourne and a man can enjoy town life with a country occupation and a ready market. Horses are cheap, and a spring cart would not cost much to take in produce. That need to be the way with farmers

of the old days. They had a spring cart which could take the family to church or produce to market but new the mansion, the carriage, the piano, and—an empty purse! No financial crises, or employers' whims, can rob you of your land and its fruit. Honest sweat in a good climate and plenty of market—surely this is tempting. Then soon there will be the comely, if not beautiful partner of one's joys and sorrows, the ruddy children, (schools are all first here)—who are indeed a blessing in a country like this. The cosy home and plentiful food. The Railway and Tram, taking you to town to pleasure, business, society, or church."

Mr. Thornton proceeds:—"He (the small proprietor) need not carefully calculate whether an outlay will be fully repaid to him within a certain number of years; he has only to consider whether the addition of the annual value of his land will be equal to the interest of the sum which the improvements will cost. He does not consider it essential that the principal should ever be returned. He is satisfied to sink it for ever in his own land, provided that, in that safest of all investments, it yields a perpetual annuity equal to what would be its annual increase in another employment." This "unearned increment is just what Europeans in Ceylon and India can never benefit from. Arthur Young, in "Traveling in France," says: "The magic of property turns sand to gold." Thus in my former paper we saw first in California and Australia real gold dug out; then rivers of water turning harrow wastes to gold; and now the "magic of property"—as a tremendous stimulant to energy and enterprise bringing profit out of small holdings. "When the hired labourer has earned his daily wages and gives himself up to rest or amusement the small free-holder is content to recreate himself by turning to some lighter work. For him it is sufficient diversion to weed and water his cabbages, or train his fruit trees."

Now comes what has been in Ceylon a curse, and may prove a curse in Mildura. It was a curse in the Scottish Hebrides. I refer to excessive population and the necessary subdivision of land when bequeathed to the numerous heirs. The 5-125th part of a coconut tree has caused amusement to outsiders in Ceylon, bitter feuds and murders among members of Sinhalese families, and fearful work in the judicial courts of the island. Mr. McCulloch in "Wealth of Nations," says: "The children of small land-owners will choose to reside in the little properties they have obtained from their ancestors, and the process of division and sub-division will continue until the whole land has been parcelled out into patches and filled with an agricultural population equally destitute of the means and the desire of rising in the world." This has been one cause of France being much crippled, wealthy country as she is. Now this is a very serious drawback with respect to Mildura. We have read how in the Scottish Hebrides the people increased by each farmer having a very large family, by each member of the family speedily marrying and having a very large family, and all attempts to occupy the same area as the first original couple occupied: then came the "Crofters' Riots" and emigration was the only means of relief to buxom women and muscular men who were simply lumbering ground which was unable to support them.

How are Chaffey Brothers to provide for what is a certain contingency more or less remote, but still certain? Will there be a law against subdivision of the blocks? How do they propose to provide for it? I might suggest that all bona-fide Mildura natives, born in the colony, will receive a grant of land from the Company to start them in life, on their attaining the age of 18 years. This would pay the Company as it would rapidly increase the number of colonists and remove the terrible evil of over-population and subdivision of property.

ABERDONENSIS.

THE TEA DUTY.

(From the *Speaker*, Jan. 30th.)

When the tea duty was reduced by twopenny in 1890, it was prophesied by the pessimists of the tea that the reduction would not benefit the public.

While they admitted that an increased consumption of tea would follow the reduction, they contended that quality would be lowered in a larger proportion than price. Consistently with their belief, they prophesied that cheap China teas, with all their drawbacks, would once again become popular, to the comparative exclusion and at the expense of Indian and Ceylon teas.

We can now look back on twenty months of results. During the greater part of the time we have had to face a great financial crisis, followed by heavy business depression and by a consequent lessening of employment, which has materially diminished the purchasing power of the working classes. For several months we were in the grip of a winter of exceptional severity—to the cost, again, of the working man's pocket. Further, during a large slice of 1891 we suffered from a positive dearth of Indian teas of the common kind. Scarcity drove them up to famine prices from February to June and lower grade Ceylons followed their lead. Circumstances, indeed, seemed in a conspiracy to minimize the increase in the consumption of tea, and at the same time to encourage the use of cheap Chinas preferably to their "British-grown" competitors.

Even during the worst of the "famine" the refusal of the public to take to China teas again was very marked. The price of these was driven up by the gamblers of the Clearing House, but only momentarily. It rose like the rocket and fell like the stick. Whatever the height of Indians and Ceylons, dealers had to take them, grocers had to buy them—at the extra rates—and to retail them at a reduction of 2d per lb. on the former retail prices. Their low-priced Chinas were saleable only on condition of being concealed in blends. The explanation is that competition in the trade was too keen to permit of the consumer being done out of the benefit of the duty reduction. In all probability he lost no part of it even then. And be it remembered that the great rise in market values during this period was entirely confined to the lower-grade teas. At one time there was but little difference between the values of Broken Pekoes, Pekoes, and Pekoe Souchongs.

For the twenty months the total increase of "Home Consumption" has been, in round numbers, 17,000,000 lb. The remission of 2d in the duty was only in operation during the last eight months of 1890, so that the more convenient method of testing the increase in consumption is to compare the completed year 1891 with 1889.

The "Home Consumption" in 1889 was (in round numbers) 185,500,000 lb.

The "Home Consumption" in 1891 was (in round numbers) 202,000,000 lb.

An advantage to 1891 of 17,000,000 lb.

The "poundage" gain is far less on paper than in reality. The increase was exclusively in Indian and Ceylon teas, and was accompanied by an enormous decrease in the consumption of China teas. It has been estimated that Indians and Ceylons show, on an average, 50 per cent greater strength than China teas; that is to say, they are capable of more economical use. Consequently, we may claim that, had China tea been our only staple last year, the increase for 1891 over 1889, in consequence of the reduction of duty would have been much more than 17,000,000 lb. Even without counting the increase, the mere displacement of China teas by British grown teas would still have argued a far larger number of cups of tea drunk in 1891 than in 1889.

The assertion that the increase is due not to the reduction of duty, but to greater liking for the new than for the old tea, may be safely rejected. Probably the "greater liking" had a little to do with the increase. But it was itself the product of the effect of the reduction of duty in lessening the price of the new teas. If, for argument's sake, we assume that the "greater liking," and not the reduction of duty, was responsible for the bulk of the increase, we are bound to the conclusion that, when the duty was reduced, the public got better value for their money. The cheapened better teas drove out the cheapened worse teas.

Before the reduction, the opponents of the tea duties contended that the effect of even a partial reduction must be to give the consumer better quality at a reduced price. They pointed out, at the close of 1889, that the duty was then equivalent to 130 per cent upon average Chinas, to 100 per cent on average Indians, to 80 per cent on average Ceylon; that any appreciable reduction must enable smaller capitals to engage in the tea trade, and that, as a consequence there would be keener competition between sellers, with the probable result that the public would get even more than the full money benefit conferred by the reduction.

To measure of the meaning of an increase of "Home Consumption" in 1891 over 1889, it is useful to note that, in view of the future production of British-grown teas, our Indian and Ceylon planters are congratulating themselves on being able to dispose of 9,000,000 lb of leaf, annually, in the Australian markets. But the reduction of duty has given them already a fresh field of consumption in Great Britain equal to *two Australias*. The 17,000,000 increase—effected under singularly adverse circumstances—is about equal to twice the total consumption of an entire continent whose inhabitants drink more tea per head than the inhabitants of any other country in the universe.

Consider, from the producer's point of view, the position at the end of 1889. A fast-rising rate of production in India and Ceylon was met by a home consumption tending towards the stationary stage as regards quantity of leaf. "Bond" values for tea were rapidly declining to a non-paying level. The new teas were more economical in use than the old, and the prospect before producers was that the supplanting of the old teas by the new would be accompanied by an actual decrease in the quantity of leaf consumed, because of the 50 per cent. greater strength of the teas. To supplant 80,000,000 lb. of the old teas only 54,000,000 lb. of the new teas would be required. To the Indian and Ceylon producer the prospect spelt ruin, unless he restricted his output or else confined his manufacture mainly to high-class teas. Either alternative would have been injurious to himself, still more so to the consumer. For cheap teas the latter would have had to revert to common China Congous, or if, after having acquired a taste for the new teas, the prospect was unbearable, he would have had to content himself with a smaller allowance of new tea—so much the worse for the cause of temperance and morality!

If notwithstanding a fortuitous combination of adverse circumstances, the reduction of twopence has already proved an important benefit to the public and to the producer, we may hope for vastly more favorable results from the remission of the remaining fourpence.

C. J. ROWE.

PERAK PLANTING NOTES.

(A Short Report on the Agriculture and Agricultural Prospects in Perak, by Mr. O. Marks, Superintendent Government Plantations, formerly of Ceylon.)

Perak is a comparatively new field for agricultural enterprise, and although a few planters are beginning to see the advantages offered to successfully cultivate such products as Arabian and Liberian coffee, cocoa, tea, cardamoms, &c., there are still thousands of acres of magnificent virgin land as yet untouched.

Unlike Ceylon the land is not divided into distinct low country and up country districts. Ranges of hills of 1,000 to 5,000 feet traverse the country in all directions, with valleys of great fertility lying between them. These hills, and in fact the greater part of the country, are covered with jungle of very fine growth. The trees growing on the ridges point to the fact of there being no wind as they are quite undisturbed and free in their growth; but in the eastern districts traces of the north-east monsoon are to be found, the trees here having a tendency to lean to the south-west. The abundance of undergrowth and number of orchids in all the forests preclude the idea

of severe droughts, so detrimental to coffee where leaf disease is liable to attack the trees.

The rainfall is evenly distributed during the year, the greatest rainfall being in October, November and December, and may be taken at an average of about 120 in. This varies considerably, and runs as high as 180 in. near high ranges of hills, which attract the clouds.

Krian comes first at present as the agricultural district of the State, there being upwards of 20 fine sugar estates, covering an area of 21,663 acres, cultivated mostly by Chinese, who, as a rule, have only primitive machinery for crushing the cane; in spite of this, 81,282 pikuls of sugar were exported from this district last year. Gula estate is under European management, and there only the latest improved machines are used for crushing the canes and refining the sugar.

Besides these estates there are huge tracts of land under paddy cultivation, and for miles round Parit Buntar some of the finest paddy land may be seen. This district is almost entirely devoid of hills, and the soil is very rich dark loam, which, when deeply drained, becomes most fertile. The rainfall in this district is about 140 inches a year.

In Larut, paddy cultivation is also largely undertaken by natives and Chinese. Pepper is also very successfully grown in this district, and may be seen on the estate belonging to Mr. Light, who has also successfully experimented in silk-worm rearing. There is a large quantity of suitable land near Taiping where the mulberry tree grows well, and as the Chinese have also taken up this employment, it is hoped that it will become one of the chief industries of the State in the near future. The rainfall in this district runs at about 180 to 200 inches.

Kuala Kangsar district has a future before it as an agricultural district. Coffee of both varieties is very successfully grown, and the natives are cultivating pepper and coffee.

Waterloo estate, the property of Sir G. Elphinstone, is under Arabian coffee, and some of the younger coffee could not look better. This estate is on the Taiping range of hills, which extends away to Upper Perak, and on which several fine blocks of land are available for Arabian coffee cultivation. Waterloo runs to between 3,000 and 4,000 ft. above sea level. Being the only hill estate in the district where Tamils are employed, some difficulty has been experienced with labour.

Government successfully grew coffee, cinchona and tea on the Hermitage and Cicely estates which are now leased out to Mr. L. Chin Hoh. Mr. Watson manages the estate, on which Chinese labour is employed, and the tea turned out compares very favourably with Ceylon tea grown at even a higher elevation. The soil on these estates is rich red loam of great depth, and would compare favourably with estates in Dimbula and Dikoya.

At Kuala Kangsar there are some Government fruit gardens where oranges, pomeloes, lemons, limes, pineapples, and other fruits are largely grown, and where nurseries are kept of gatta, cocoa and all kinds of fruit trees for distribution and sale among people requiring them.

Kannang estate shows how successfully Liberian coffee can be grown. Nothing could look better than the trees, which are bearing very heavily, and this year give promise of a very large crop. The soil here is very rich, and the finest fields are those near the limestone hills in the centre of the estate. A large number of these limestone hills are to be found both in the Kuala Kangsar and Kinta districts, and the soil near them is especially suitable for Liberian coffee. Several large native Chinese pepper gardens are near Kuala Kangsar, and the natives are also beginning to cultivate coffee.

Kinta is a large district with a very rich soil, and several ranges of hills run through the district. The Kinta Village is cultivated principally by the Malays, who are planting up coffee as quickly as possible, the demand for the seed being very large. Rajah Mahomed has a garden of over 100 acres planted

with coffee and all kinds of native fruit trees near Batu Gajah; and at Batu Gajah, Father Allard, the Roman Catholic priest, has a large acreage of land cultivated by his Chinese converts.

The railway from Teluk Anson to Ipoh runs through the Kin'ra Valley, and will, when completed, enable the fine land towards the Sim hills to be opened up. Batu Gajah is also connected with Taping by a fine metalled cart road and the land between Kamuning estate and Ipoh is all suitable for the successful cultivation of coffee, cardamoms, cocoa, tea, and especially Liberian coffee, as along this road timber trees are to be found in great number.

Lower Perak is a district very much like Krian in many ways; it is almost devoid of hills, and the soil is of the same nature. All round Teluk Anson land has been let out in small blocks to Tamil immigrants, who now have very valuable little gardens, planted with fruit trees of different kinds, and tapioca, sago, &c. A cart road is now being constructed to open up the land lying beyond Changkat Jong, which is of very fine free soil, in which almost anything grows luxuriantly. Some very fine nutmeg trees can be seen here quite free from disease, and bearing very heavily. Sungai S'tiawan is a large settlement of Javanese, in the Lower Perak district, and here nilam or patchouli is grown in very large quantities. Pepper, coffee and tapioca are also grown here with very good success, some of the pepper having been produced to be as fine as any grown in the State. Land is being given out here every day to new immigrants, and before long the whole of the land between Sungai S'tiawan and Passir Panjang will be under cultivation.

Transport in the country is very easy, either by road or river, and in three years the Kin'ra Valley Railway will be a means of transport for any estates opened in the Kin'ra Tapah, and Teluk Anson districts. Good metalled cart roads open up the best land and traverse nearly the whole state, besides there being many elephant paths through the thicker jungle towards Upper Perak.

The labour used is mostly Tamil, and although the rates of pay are rather higher at present, there is every prospect of labour becoming cheap and plentiful. The Government now rule that all contractors for large public works must import at least 50 per cent of their labour, and this brings a large number of coolies to the country. Felling and clearing works done by the Malays, who are good men at jungle work. Every inducement will be given to encourage planters to take up land in Perak, and already several large blocks of land have been chosen by Ceylon planters.—*Perak Hand-Book*, 1892.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, Feb. 10.

CINCHONA.—The auctions held on Tuesday were rather slight, the total weight of the bark offered being about 20 tons, composed as follows:—

	Pkgs.	850 of which	800 were sold
Ceylon	...	750	do
East Indian	...	149	do
Java	...	312	do
South American	...	10	do
African (West Coast)	...		

Total 2,110 do 1,776 do

The competition was good throughout the sales, and the market remains very firm, although the advances occasionally paid over the last auctions were so slight as to be practically inoperative. The unit averages fully 1½ per lb.

The following are the approximate quantities purchased by the principal buyers:—

	Lbs.
Agents for the Brunswick works	116,583
Agents for the Mannheim and Amsterdam works	105,471
Agents for the Frankfurt o/M. and Stuttgart works	70,811
Messrs. Howards & Sons	55,485
Agents for the Italian and American works	37,819
Agents for the Auerbach works	15,975
Sundry druggists	16,320

Total quantity of bark sold

Bought in or withdrawn

Total quantity of bark offered

Messrs. Lewis & Peat review the position of cinchona bark and quinine as follows:—Although the advices by wire show a large falling off in Java bark shipments for December and January, it is probable that, unless artificial restraints are enforced, supplies from Java will continue very large for this and the next year or two. Ceylon shipments will probably again show a falling off for 1892, while we look to see those from India and Bolivia fully maintained. The imports into London during 1891 showed a decrease of about 1,500 packages, the falling off being almost entirely in Ceylon barks, East India.—Imports of Wyand and Nigiri show an increase of nearly 2,000,000 lb.—viz., 4,800,000 lb., against 3,080,558 lb. in 1891. The average price obtained during 1891 was 3½ per lb. Bolivian.—The quality brought forward was rather better than in the previous year, and met a ready sale when importers accepted market values. Central American.—The imports have again been insignificant current rates being prohibitory. West Coast African.—766 bales, weighing 97,000 lb., chiefly druggists descriptions have been offered and sold at from 2½ to 6d per lb. Jamaica.—Nothing offered of any note. Darjeeling.—190 bales, weighing 21,000 lb., mostly old import, were offered and sold at auction from 1½ to 4½ per lb. Ceylon.—During the past year 21,275 bales, weighing 5,345,000 lb. were offered, of which 18,683 bales, weighing 4,830,750 lb. were sold; against 30,113 bales, weighing 7,715,255 lb. offered, and 23,862 bales, weighing 6,359,630 lb. sold in 1890. The average price obtained for Ceylon barks during 1891 was 2½ per lb.

QUININE.—Towards the end of last week a sale of 10,000 oz of Brunswick quinine at 10½ to 10¼ per oz spot was reported. Since then the market has gone dull and lower, and today it is said 4,000 oz second-hand have sold at 30d per oz. There are further sellers at that figure. The following notes are taken from Messrs. Lewis & Peat's annual review of quinine:—"The sale and resales of quinine in Mining Lane over 1891 (partly for export, but chiefly on speculation) show a marked falling-off when compared with 1890. We estimate them at about 2½ millions of ounces, against about 3½ millions in the previous year. The shipments from Europe to America have also decreased, and we estimate them—including quinine in bark to manufacturers—at rather under 4 millions of ounces, against 4½ millions in 1890. The total quinine contents of barks that have passed into the hands of manufacturers during the year we estimate at rather under 9 million ounces, as against 9½ millions in 1890. This is to some extent accounted for by the fact that one large factory on the Continent has suspended working for the past six months. With such figures as these it is difficult to recognise the possibility of consumption over the world having increased to such an abnormal extent over the past two years as to have occasioned the material reduction of the excessive stock in second-hands which is currently reported. We estimate the quinine contents of the London and Amsterdam stocks of bark at about 6 million ounces."

NOTES ON POPULAR SCIENCE.

By DR. J. E. TAYLOR, F. L. S., F. G. S., & C.,

EDITOR OF "SCIENCE GOSSIP."

There is little doubt that synthetical chemistry is at present only in the cradle. For seventeen or eighteen years past the belief has been growing among chemists that the sixty or seventy "elements" are in reality compounds, or dynamical modifications of the same matter, whatever the latter may be. Professor Austen has recently reminded us that the researches of certain chemists have demonstrated that the atomic weights of the chemical elements occupy definite and unchangeable positions in a geometrical figure, and that the properties of matter may be considered merely as mathematical functions of numbers. Not long ago a distinguished German chemist split up the metal didymium into two other elements, thus proving, what has for some time been suspected, that some of the heavy metals could be resolved into simpler elements, if we had the requisite forces wherewith to break them up. Welsbach, the German chemist just referred to, as the conclusive demonstration of his discovery, then reunited the new elements and restored them to their didymium state. Some time ago, the most brilliant of our English philosophical chemists, Professor Crookes broke up the element yttrium into a number of new substances, which he also reunited into the yttrium state. Lastly, another German specialist has published his conclusions, derived from spectroscopic research, that all the chemical elements can

be reduced to two primary forms. Iodine has been heated until it assumed the atomic condition. Among the rarer and heavier metals is gold, and Professor Auston thinks that if it were subjected to the same treatment as didymium and yttrium, it would be resolved into something else, could be recombined into the gold state, and thus teach us how to make gold.

Most Englishmen, and men of English descent, love their beer. I never yet met either a brewer or a publican who did not sell good, sound beer. Nevertheless, the trade organs are crowded with advertisements of various drugs and chemicals all intended, of course, to make "good, sound beer" better. A great "trade" authority, the other day, when under examination, ingeniously defined beer to be "a fermented, saccharine, fluid, flavoured by some bittering principle." The popular notion that beer is always made from malt and hops shows what a many-headed old fool the public is, and how simple-minded is its trustfulness. Most of the beer sold knows nothing of malt and hops. It knows more of sugar and molasses, and quassia, cocculus indicus &c. These "bittering principles" go by the euphonic names of "hop substitutes," and, of course, are many times cheaper than hops. When the new Beer Bill comes into operation in England, obliging brewers to state on the outside of the cask what the liquid within has been concocted from, I expect there will be some fun.

I have, on several occasions, called the attention of my readers to the exceedingly ingenious experiments and discoveries of Professor Boys, one of the youngest of our eminent scientists. Some time ago he exhibited at the Royal Institutions, and also before the Royal Society, the results of his experiments with his artificial fibres of quartz. At the recent British Association meeting Professor Boys delivered a discourse on the subject. How fine these artificial quartz threads can be made was illustrated by means of the oxyhydrogen lantern and screen. A living spider was shown running over the lines of its own web. The spider was then transferred to a web made of the artificial quartz fibre, but the latter was so much more delicate and smooth that the spider could be seen slipping about like a bad skater on unusually smooth ice. How sensitive these quartz threads can be made was shown from the fact that the heat from a candle at the extreme end of the hall was sufficient to turn a mirror suspended by one of the fibres. Even a musical note had the same effect. Professor Boys demonstrated that the attraction of gravity of the twenty-five millionth part of a grain, acting on a torsion-balance made of quartz fibre, can be rendered visible.

A curious fact has just been brought before the notice of the Paris Academy of Sciences, by M. Bonnier, that the amount of carbonic acid decomposed by plants increases with the altitude. One would have thought the opposite to have been the case, seeing that the lower strata of the atmosphere are more charged with that gas than the upper. Facts, however, are proverbially stubborn things. M. Boumier shows that plants cultivated in an Alpine climate undergo a modification of their functions such that the assimilation and transpiration due to the green colouring matter (chlorophyll) are augmented, whilst respiration and transpiration in the dark are little modified or slightly diminished.

With regard to the chlorophyllian assimilation by plants with red leaves, another French scientist, M. Jmelle (who has been specially investigating the subject), proves that in trees with red or coppery-coloured leaves the chlorophyllian assimilation is always more feeble than in trees of the kind which bear green leaves. The intensity in the copper beech and the purple sycamore is only about one-sixth that of the ordinary types of the same trees. Coloured leaves, therefore, are in all cases evidence of decreased or decreasing vitality.

The following is a capital receipt just given in the *Journal of the Royal Microscopical Society*, by Professor Goddall, for the disintegration of woody tissues, which may be of practical importance to some of my readers. The tissue is soaked for a sufficient length of time in a ten per cent. solution of

bichromate of potassium, then quickly freed from the excess of the salt by once rinsing in pure water, and immediately acted upon by concentrated sulphuric acid. After the acid has acted for a short time, the tissue must be placed in a larger quantity of pure water, and immediately it will be found to have undergone more or less complete disintegration, each structural element being separated from its neighbours, with little or no corrosion of the wall.

We have heard, at various times within the last few years, a good deal about the wonderful action of the new drug cocaine. Now, I have just heard from an Indian surgeon, Dr. Pant, that he injects cocaine hydrochlorate (half to one grain in ten to fifteen drops of water) hypodermically, as a cure for the stings of scorpions. He has been injecting it at or near the seat of the sting, with the result that the pain is gone before the nozzle of the syringe is withdrawn. A fresh solution acts better than one long kept. Dr. Pant has used it in nearly one hundred cases, without the slightest untoward symptoms. He says that during May, June, and July scorpions abound in Srinagar, in Garhwal, India, particularly after a stormy or rainy evening. A village a few miles distant from Srinagar was deserted, owing to the scorpions in it. Of course, all the rest of India is not like Srinagar in this respect. I do not see why the remedy above mentioned should not be applied to the bites of venomous snakes.*

A very practical paper was read at the recent meeting of the British Association at Leeds, by Mr. Thomson, of Manchester, on vulcanised indiarubber. He showed that copper salts have a very injurious effect on this well-known substance, and, as copper is not unfrequently used in dyeing blacks and other colours, the indiarubber cloth so dyed are liable to decompose, and the rubber to harden on their surfaces, or in their tissues. Mr. Thomson stated that metallic copper placed in contact with thin sheets of india-rubber brings about oxidation and hardening of its substance, although no appreciable quantity of copper enters the indiarubber. Metallic zinc and silver have no appreciable effect on the rubber. When oils contain the slightest amount of copper, which they often do, and ordinary cloths are oiled with them, or if the oils come into contact with them or the action of the bleaching agent on the copper damages the cloth. Linseed oil contains an acid which damages cloth. The well known smell of indiarubber is a sign that it is decomposing. Indiarubber can best be preserved in water, glycerine, or coal gas. All oils, except castor oil have a very injurious effect on indiarubber.

A French scientific agricultural journal has been discussing the important question as to whether hay, and then water, and afterwards oats, ought to be given to horses; or whether the hay and oats should be given them before the water? The first plan is recommended, on the ground that drinks ought to be given after a meal of dry and fibrous foods, as they aid digestion. Water, however, should not be given after grains, possessing a floury substance, whether the latter be bruised, broken, or softened. All animals should take water before they receive grain, and if fed on cooked foods, they ought to drink frequently but very little—tipple, in short.—*Australasian*.

NOTES FROM PEERMAAD.

February, 1892.

It is with much satisfaction that I note the improved averages for Travancore tea generally, and especially for Peermaad. Your correspondent, St. Louis, some time back, drew attention to the low prices then prevailing, and attributed them to the desire on the part of the planter for quantity not quality, in fact to coarse plucking. In this surmise, however, he was incorrect. At the time, there was a general depression in the market and the teas referred to were monsoon growths, which seldom, if ever, equal the produce of the drier months of the

* And to those of centipedes, which are worse than scorpion bites.—*Ed. T. A.*

year. By the bye, I most unintentionally did some of my friends an injustice in my last "Notes" when alluding to the cost of plucking, and for this I apologise most sincerely. The average cost of plucking in this district is considerably cheaper than in Ceylon, and with this we ought to be satisfied. By last mail I received a letter from an old Travancore planter, from whom I have not heard for many a long year, who, after alluding to the great pleasure with which he reads from time to time "those interesting notes from Peermad"—one for me, Mr. Editor?—extracted from the *Madras Times*—(I am writing by next mail to tell him he should subscribe to *The Times* and so get his notes, &c., direct—one for you, Mr. Editor?) asks me the following pertinent question:—"Why do Ceylon teas bring to much better prices than Travancore?" and adds "they certainly are not a bit better in the cup." The italics are mine.

To him I would reply:—"Prestige and advertising," and, I would add, with all humility, that even Ceylon cannot expect to live for ever on the former, and that that Travancore will soon go in for a little of the latter.

To give your readers some idea of the strides tea is making in Peermad, I cannot do better than describe a visit I paid last week to "Bon Ami," the largest tea estate in this district, and unless I am much mistaken, in Travancore. Bon Ami is situated on the northern side of the Annan-Thurly Ridge, which separates the Perinthuora from the Peermad (proper) and Arrnday country. The range of hills run almost due east and west, for about 10 miles, from the big peak of Ammeratha Malia on the west to Shaitan Malia on the east; the only break being at the foot of the latter, where the Peryar rushes through a gap, a little over 20 yards wide. By the bye, it has often struck me, that this is the spot that should have been selected for the great dam which is being built across the river some 15 miles higher up. There is only one drawback that I know of, and that is, that the one very fine coffee estate, and two equally fine tea gardens would have been completely submerged, and the amount of compensation that the proprietors of these properties would have demanded would probably have reduced the Government of India to a state of utter and hopeless bankruptcy!

From the verandah of the Manager's pretty little bungalow—by the bye, I hear, he is to have a new one soon, and not before it was wanted—one obtains a lovely view of the grand old peaks; but I must not linger over views, lovely though they be nor trespass on your space by even an allusion to the wealth of lovely flowers, so tastefully grouped about the little "bijon" of a garden, but proceed to business, and to the factory, which, a most imposing cruciform edifice forming a very conspicuous feature in the landscape, stands to the left front, and within a stone's throw of the bungalow.

When I mention that the withering lofts measure some 400 by 24 feet, you will have some idea of the capacity of the buildings. But it is the machinery that naturally attracts our chief attention. A new 20-horse power engine has just been erected by Mr. William Pottie, Engineer to the Colombo Commercial Company, Limited, (who came over expressly from Ceylon to erect two of Brown's Dessicators, which have lately been introduced into this district, and of which I shall have something more to say later on). The fly wheel, 9 feet in diameter and weighing 3 tons, took the greater part of a month in its journey from the coast to the estate and, if no body or thing also deserves it, great credit is due to the wheel for having behaved itself so well under very trying circumstances. Having duly admired the engine and its surroundings our attention was drawn to the two Jackson's 32-inch Rapid Rollers, the Senter's Patent roll-breaker and sifter combined, by Brown, Rae & Co., of Hatton, Upper Dikoya, Ceylon; a most perfect machine, acknowledged to be the best, especially since the new motion gear has been added. Next come the two large Davidson's Siroccos, one up, and one down-draft, and then, "the gem of the Factory," a Brown's No. 2 Dessicator (tea drier). The working of this is simplicity itself, and certainly

the Dessicator not only does, but does well; all that the makers claim for it. It is simple and easy to work; it is next to impossible to burn the tea, as the temperature is under perfect control, it is economical as regards fuel, the power required to work the exhaust fan is nominal, and the leaf requires no hand turning, as the hot air current passes alternately through the trays, first from below and then from above. The Dessicator is made in two sorts. No. I. turns out 80 lb., and No. II. 120 lb. tea per hour. In addition to this, an Elston's patent carer is shortly expected, and then I think the manager will, for a time, at any rate, feel perfectly satisfied with his machinery. I may mention that "Bon Ami" is expected to turn out during the present year 250,000 lb. of tea.

"Kudawa Karnum," and "Gleu Mary" are the only two other estates that have erected steam machinery, and I may have something to say about them on another occasion. While on the subject of machinery, I may mention that Messrs. Brown, Rae & Co. of Hatton referred to above as the makers of the patent Roll breaker and Sifter, have also patented a triple action Roller,* of which I hear most excellent reports. It requires only 2 horse power to drive it and rolls 300 lb. of leaf: *verb. sup.*—*Madras Times*, Feb. 24.

COLOMBO COMMERCIAL COMPANY, LIMITED.

DIRECTORS

John Brown, Esq., *Chairman.*
Edward Conder, Esq. | L. Famin, Esq.
H. H. Potts, Esq. | Norman Stewart, Esq.

REPORT.

To be presented to the Seventeenth Ordinary General Meeting of the Company, on Monday, the 22nd day of February, 1892, at 12:30 o'clock p.m.

The Directors are now able to place the following Annual Accounts before Shareholders, viz:—
Profit and Loss Account for the year ending 30th September, 1891.

Balance Sheet made up to 30th September, 1891.		
It will be seen from these Accounts that the result of the year's operations is a profit of	...	£5,453 13 9
A balance was brought forward from last year of	...	221 0 6
Making a total at the credit of Pro. fit and Loss of	...	£5,679 14 3

The Directors propose to apportion this sum as follows:—

To the payment is full of the Dividend on the 6% Preference Shares for the year ending 30th September, 1891	£1,089 0 0
To the payment of a Dividend] of 5% on the Ordinary Shares for the same period	3,500 0 0
To be carried to next account	1,090 14 3
	£5,679 14 3

Under careful management, the Company's General Trading business has made satisfactory progress during the past year.

The result from the working of Company's Estates has also shown an improvement. This was due to increased crops of tea being secured, and the yield should continue to improve as the tea bushes mature.

The area under tea on the Company's Estates has been added to during the year, and now stands at 1,510 acres, and the Board are still further extending the area under this product.

The Tea Market at the present time is low, no doubt due to the increased supply from Ceylon, but partly as a set-off against this, it is satisfactory to report that the price of silver keeps down. The im-

* "Triple action roller"? Is there another "Richmond [Brown] in the field"?—Ed. T. A.

portance of opening up new markets abroad for the consumption of tea cannot be over-rated, the yield from Ceylon having increased from 47,000,000 lb. in 1890 to 68,000,000 lb. in 1891, and the yield for 1892 being estimated at 85,000,000 lb.

Mr. John Brown, Chairman of the Board, left for Ceylon in October, and will inspect the properties in which the Company is interested.

Mr. Edward Conder, a Member of the Board, retires from office on this occasion, and being eligible, offers himself for re-election.

Messrs. Deloitte, Dever, Griffiths & Co., the Auditors, also offer themselves for re-election.—By order,

J. ALCO ROBERTS, Secretary.

London, 13th February, 1892.

BALANCE SHEET, 30TH SEPT. 1891.

Dr.	Capital authorized:—		£	s.	d.	£	s.	d.

WYNAAD PLANTERS' ASSOCIATION.

Proceedings of a general meeting held at Vayitr Jubilee Hall, on the 3rd Feb. 1892:—

Roads.—Read extract from the proceedings of the Taluq Board (dated 16th November 1891, and received by the Association in January, 1892), in which a proposal is made to alter the trace of the Kulpetta-Moppadi road; approved of. The Honorary Secretary was instructed to write again to the President of the Taluq Board and call his attention to the complaints made about the state of the Sultan's Battery-Tulloor bridge road, of which he has taken no notice.

Coffee stealing.—Insufficient sentences.

Read judgment given in the court of the 2nd Class Magistrate of Gndalur, dated 29th December, 1891, Calendar case No. 333. The chief offender is the head man of the Pundalur Badugars and was caught in the act of stealing. He is sentenced to three months' rigorous imprisonment and £20 fine for his audacity in having "ventured to commit theft on the Estate of a European planter whose proper guards are sure to be stationed."

Read letter from Mr. W. R. McKenzie reporting the detection of a coffee receiver at Kulpetta and asking for a reward to be given to the Police. The Honorary Secretary was instructed to apply for the official records of the case.

Cinchona.—Read Government Order 11th January, 1892. No. 211 forwarding a letter to the Madras Government from the Governor-General of Netherlands India, dated Buitenzorg 28th October, 1891 No. 27, Cabinet, forwarding a statement showing the areas under Cinchona cultivation in the island of Java on the 1st January, 1891.

The figures show an area of 18,126 bouws of land, equal to 31,000 acres approximately.

The Honorary Secretary was instructed to thank Government for having obtained this information.

Tea.—The Honorary Secretary stated that Mr. Punnett had favoured him with the following report and valuation made on his tea by Messrs. Patry & Pasteur. January 6th, 1892. 38 Mining Lane, E. C.

These Teas are as near perfection as possible; there has been nothing to approach them in quality offering on this market for some time and a ready sale would be commanded at once. The infused leaf is very bright, and the liquor when hot draws ruby red, which is so much liked. With fine sized breaks higher prices than our valuations might be realized.

Pekoe Souchong.—Brownish grey leaf, fine pure flavour, 1s 1d to 1s 2d per lb.

Pekoe.—Brownish grey fairly even twisted leaf mixed gold, bold tips, thick rich Pekoe flavour 1s 8d per lb.

Orange Pekoe.—Very hand some Pekoe leaf with fine golden orange tips, thick rich Pekoe flavour 2s 4d to 2s 6d per lb.

Broken Pekoe.—Even blackish crapy leaf, some tips, fine strong crummy liquor 1s 8d to 1s 10d per lb.

Dust.—Should be marked Orange Pekoe fannings. Brownish very tippy or Pek; fannings, thick and strong liquor nominal 1s to 1s 2d per lb.

ESSENCE of cinnamon is asserted to have been used with excellent results in the hospital in Margue-lane, in Turkestan, in the treatment of all forms of malaria. Spraying the essence several times during the day in the wards is alleged to have proved more efficacious than eucalyptus, and to have met with success in cases which have resisted the action of quinine and arsenic.—Fiji Times.

THE REPORT OF THE COLOMBO
COMMERCIAL COMPANY.

When recently making some comments upon the report of the Lanka Plantation Company, we remarked that such documents, when issued by companies that have worked through the transition period from coffee to tea which Ceylon has passed through, were possessed of far more than the ordinary interest attaching to the reports of more recently established Associations of the kind. We observed that such reports indicated the results to the endeavours made to overcome the difficulties consequent upon that transition, and that they therefore formed a sort of mileposts, marking how far this colony had emerged from the heavy cloud which for so long overhung it. The Colombo Commercial Company, with whose latest report we propose now to deal, is one of those companies. All of us must remember for how many years its shareholders have had to deny themselves any return—or at least any adequate return—upon their investments; and for a long time it seemed almost impossible that a day of brighter things could dawn for them. Gradually, however, the heavy coach has been drawn out of the slough of despond; and year by year we have seen the dividends paid slowly increasing in amount and giving promise of better things in store for the unfortunate and long-suffering shareholders. The report under review informs us that for the past year not only will the full payment of six per cent be made upon the preference shares of the Company, but that after doing so moneys will remain available to pay a dividend of five per cent on the ordinary shares. It cannot, of course, be pretended that five per cent is an adequate dividend, or one, indeed, that can be regarded as anything but trifling, as compared with the dividends paid by tea companies working in this island of later establishment than is the Colombo Commercial company. But everything, it is justly said, is comparative; and we have only to exercise a reminiscence as to the dividends of previous years to acknowledge that there is now good cause for congratulating the shareholders on the present dividend, and on their future prospects. The character of the Colombo Commercial Company sets it apart by itself from those other Associations working in Ceylon with whose reports we are in the habit of dealing. It is not alone a planting company, but it is besides a trading company; and the second function must necessitate a greater reticence ruling the character of its reports than has to be observed as regards those of companies having the first function only. Hence it follows that we are unable to deduce from the terms of the present report the interesting details always to be obtained from those of other Ceylon companies. But although we admit the necessity for the exercise of the reticence we have mentioned, we can scarcely admit that there need exist any with regard to the noticeable exclusion from this report of any figures showing, for instance, the quantity of produce from the Company's estates and the price obtained for it. We can only imagine that the directors fear, were they to give such information, that shrewd guesses might be made by the outside public as to the balance of profit which has arisen from merely trading transactions. With these last we do not, however, concern ourselves. Doubtless the shareholders will be permitted to learn all the facts which are kept back from outsiders. It contents us to know that the Company, as one strongly representing both planting and trading interests in Ceylon, has at length

seemingly secured an improved and stable position once more, so evidencing that in both respects this island is advancing towards fully regaining the standard of prosperity of a former epoch.

MR. CLARK'S REPORT ON PERU.

This able, comprehensive and well written document will astonish those who have appreciated the intellectual calibre and the literary accomplishments of the gentleman who has, on its titlepage, styled himself "Curator" of the Peradeniya Botanical Gardens his real status being that of Head Gardener. The more would it be to his honour if the elaborate report of which we publish the first part today were his own in matter in style. But "the Commissioners," to whom Mr. Clark alludes rather patronizingly, complain, we have good reason to believe, that the member of the expedition who was deputed to report especially on the flora of the regions traversed has taken advantage of his association with them to steal their thunder, the lightning of the style being supplied by "a clever Glasgow sub-editor brother." We have learnt that "it was entirely Mr. Sinclair's idea to judge of rainfall or moisture by the character of the vegetation, and the spring-water which Mr. Clark got analysed was simply entrusted to him by Mr. Ross to carry home. In fact what is of value in the report (a cleverly written one) is not Mr. Clark's own, and what is his own is most unreliable, in some cases nonsense (about sugar for instance)." Sharp practice of this kind is more clever than creditable, and the Commissioners, who find themselves anticipated with their own observations intended for their comprehensive and general report, by one who was attached to the expedition in a special and subordinate capacity, will no doubt represent the matter to the Corporation. Of course this does not lessen the value of the really reliable portions of Mr. Clark's report, for which he so successfully sucked the brains of two such able and experienced observers as Messrs. Sinclair and Ross, whose more elaborate reports when they appear will be placed at just the disadvantage which attends the full report of a speech, the more interesting and important portions of which had previously appeared in a summary form. Indeed we suspect many of the directors and shareholders, when they have read and digested Mr. Clark's report, and carefully examined the elaborate coloured map which accompanies it, will be apt to doubt the utility of the further and more extended reports which it is the duty of the Commissioners to furnish. Anyone merely reading Mr. Clark's report and not knowing the circumstances would certainly conclude that he, with his boasted eleven years of tropical experience and delivering *ex cathedra* judgments on soil, climate, vegetation, cultivated crops, labour, communications, prices, demand, &c., was really the head of the expedition whom the Corporation had specially appointed not to report on vegetation and flora alone, but to deliver final judgment on every possible question involved, from soil and seed to altitude and climate. The only points he has left untouched are the rather important problems of upheavals, political and natural; social earthquakes and volcanic outbursts. Such cataclysms apart, there is abundance of excellent soil: in dry regions on the banks of rivers, the waters of which afford means of irrigation; and, better still, in uplands well supplied with rain, where all tropical products grow and where, beyond all, coffee, unaffected by any disease, flourishes up to an altitude of 6,000 feet,

Malaria is absent; and all that is wanted is the presence of a sufficient labour supply. A good account is given of the Indians who at present labour on estates. But they are not sufficient even for present requirements. Mr. Clark, however, with his long tropical experience, sees no difficulty, in what many regard as the difficulty. Are there not Tamils and Chinese in multitudes? Yes; and the latter once were employed in Peru under circumstances which led to trouble. The two great difficulties are connected with political peace and an adequate labour supply. But Mr. Clark proposes, as an initiatory measure, the establishment of an experimental garden of which he would no doubt consent to take charge. As we mean to publish the whole of this elaborate and interesting report, we need not indulge in further remarks about what may be regarded apart from the merits of its matter, as a literary curiosity and the certain source of an addition to 'the quarrels of authors.'

THE PERUVIAN CORPORATION, LTD.

REPORT ON THE CENTRAL TERRITORY OF PERU, BY
P. D. G. CLARK, CURATOR, ROYAL BOTANIC GARDENS,
PERADENIYA, CEYLON.

66, Old Broad St., London, E.C., 19th Dec. 1891.
To the Directors, Peruvian Corporation, Limited,
London.

GENTLEMEN,—I have now the honour to submit herewith my report upon the expedition into the interior of Peru undertaken by me at your request.

That a better idea may be conveyed of the country traversed, I have thought it advisable to accompany this report with a map, on which are indicated, by distinctive colours, the different conditions of climate and agriculture.

Of the country traversed I have treated—

First.—That part lying between the Coast and the great Andean range of mountains.

Second.—The mountain or cold zone, included in which is the milning region.

Third.—Tarma and the lands adjacent which may be included in what I term the temperate zone.

Fourth.—The district lying between the limit of the temperate zone and Naranjal, which I term the semi-tropical zone.

Fifth.—The Chanchamayo Valley and its various industries, in what may be called the tropical zone.

Sixth.—The land selected by the Commissioners appointed by the Corporation, situate in the region of the river Perené, the flora and wild products, with suggestions on what appear to me to be the best means of development.

Seventh.—Huanuco, the centre of coffee plantations. Labour.—So important an item in the success of this undertaking as labour has also received my careful attention, as well as other subjects of interest to the Directors of the Corporation.

I trust that my report, after perusal, may be considered as in some measure commensurate with the importance of this great field of enterprise.

The true agricultural wealth of Peru exists in its vast interior region. An extent of land on the western slopes of the Andes and adjacent to the coast has, however, an interest peculiarly its own on account of the capital employed in the various industries already existing.

The country lying between the coast and the western chain of mountains known as the Cordillera de la Costa, is so influenced by the dry climate (a feature of this district) as to be of necessity a part of the country unlike any other on the opposite or eastern slope of the mountains. To account satisfactorily for this state of matters is beyond the scope of this Report; but I am of opinion that to the Antarctic current, which sweeps the western shores, may be attributed the chief cause.

Extending about 15 miles inland, as if forming at one time a natural sea bottom, is a stretch of land at present under cultivation; and to this region

and its capabilities I shall now shortly address myself before treating at length on the country beyond the Andes, a district of more interest to the Corporation.

COAST DISTRICT.

The atmosphere is dry and bracing during the day time. At night heavy dews fall upon the lower reaches of the hills, especially during the winter months, which extend from June to September. To the absence of sufficient rain may be attributed the want of abundant vegetation, but what the country lacks in rainfall is compensated in the adaptability to irrigation.

All the available land in the highly fertile valley of the Rimac is occupied, the river serving as a means of irrigation. The soil is chiefly composed of disintegrated rock, and is, therefore, of a light sandy character, but is capable of producing prolific growth.

The flora is of a truly dry country type, supported by the heavy dews, and is chiefly represented by Cactaceae and straggling Solanaceae plants with half parasitical Bromeliads. The number of exotic species is not large, especially in timber trees; but I see no reason why the Australian flora should not be drawn upon with advantage to the surroundings, such as the more profitable species of Eucalyptus and Acacia, the former yielding timber and fuel of a superior quality and of rapid growth, the latter, while useful for timber and fuel, being extensively grown in similar climates for the useful commercial properties of its bark for tanning purposes.

In treating, throughout my Report, of the various agricultural products, I propose dealing with each product relatively to its importance agriculturally.

Sugar cane is undoubtedly the chief product here. The variety of sugar grown, while yielding a fair average return, is not in my opinion equal to the varieties selected in such colonies as Mauritius and Demerara, whose exhaustive experiments have been carried out.

A high state of cultivation exists on the more important plantations around Lima, where the implements used are of the most modern type, with a consequent saving of labour. The planting adopted here is that usually in practice in most sugar producing countries where irrigation is carried out. The cane is so planted as to allow of a succession of cuttings being made throughout the year.

On investigation I find the average yield per acre to be about $2\frac{1}{2}$ to 3 hogsheds of refined sugar. The exports during 1889 amounted to 45,000 tons, a ready market for which was found in Chili and elsewhere.

My experience in tropical agriculture enables me to state that the plantation in this vicinity could be more economically conducted, especially in out-door management.

Cotton gives indication of being a promising product wherever it is grown within easy reach of transport. The climate is eminently suited to all the varieties, while the plantations are remarkably free of all insect pests so common to this plant in other countries.

The descriptions cultivated are chiefly the New Orleans and Peruvian varieties, while the Tinnovally and other less valuable sorts are also represented, the two first-mentioned yielding a cotton of superior staple and excellent quality. The plant seems to crop well, but no definite information could be obtained of the yield per acre. I was assured by most of the principal growers that, were several cleaning mills erected in central situations, the cultivation of this plant would be largely extended.

Maize is more generally grown in small patches around houses than in the form of large plantations. This important grain enters largely into the food supply of the people throughout Peru. The varieties are numerous and their productiveness is unequalled.

Attention is paid to vine cultivation by a few Italians in the vicinity of Lima, who assured me that it was a remunerative industry. This might, in my opinion, be largely extended by practical vine growers. The climate, along with irrigation, is certainly suited to the production of a high-class grape.

On investigation I found that "Phylloxera" had not yet appeared.

There are other economic products grown around Lima such as olives, *Opuntia vulgaris* (the edible "prickly pear"), as also the *Opuntia cochinellifera*, upon which the cochineal insect (*Coccus cacti*) lives.

I was also shown specimens of "Rhea," or China Grass (*Boehmeria nivea*) which was the finest sample of this valuable fibre plant that I had ever seen. It measured 9½ feet long, and had also the appearance of having been cut too soon for commercial purposes.

This plant only awaits the invention of machinery for the separation of the fibre to make it one of the most extensively cultivated products.

HILL REGION.

Commencing our journey by rail and passing up to an elevation of 7,000 feet above the sea, we traversed a country almost in every respect similar to that just described.

At Matucana (7,788 feet) a cereal-producing district is entered upon, thinly populated by Chola or Hill Indians, who take full advantage of every stream of water to irrigate their small patches of wheat, barley and root crops. Amongst the fruits produced in this district are peaches, apples, pears, palta or Avocado pear, figs, oranges and chirimoya, which are mostly grown in the vicinity of the stations, where they find a ready market.

The topography of this region is very irregular and renders cultivation difficult.

The cereal and root-producing districts would appear to extend from an elevation of 7,788 feet to, in sheltered situations, 12,000 feet.

On leaving Chila we enter a rich mining district with Yauli as a centre, immediately ascending to the summit at 16,700 feet elevation, and thence descending by way of Pachachaoa and Oroya. The road leading to Tarma from Oroya immediately ascend until the summit of the most easterly range of the Andes is reached at an elevation of 16,700 feet, the distance from Chila being about 62 miles by road.

This tract of country possesses few if any attractions to the agriculturist, chiefly owing to its extreme altitude and consequent low temperature. The soil, moreover, is poor and is productive of little vegetation other than pasturage.

The grazing land around Oroya is, however, capable of rearing large flocks of sheep, and is only partly occupied by a few Indians and their flocks.

This ore-producing zone embraces such rich silver mining centres as Vaull and Cerro de Pasco, and need only here be mentioned as presenting a large field for further development by capitalists interested in this industry.

The flora of this district is chiefly represented by herbaceous perennials, with short grasses, and is of little interest beyond that of a cold mountain flora.

The supply of labour required for the existing mines in the neighbourhood of the railway is drawn from the more populated villages at lower altitudes. The men are paid at the rate of 70 to 80 cents of a sol, with small perquisites.

Cerro de Pasco and its neighbourhood is dealt with towards the end of my report.

TEMPERATE ZONE.

Extending from 13,000 feet to 8,000 feet; or in the locality of Palca. Coloured yellow on the map. Average temperature, taken in July and August at Tarma, maximum 72 deg. minimum 52 deg. Fahr. (In shade).

On reference to the map accompanying my report it will be observed that this zone includes important centres of trade and agricultural conditions in the interior.

The climatic and general characteristics of the eastern slopes, looking down upon the Amazonic region, at an elevation of 13,000 feet, are similar to those found upon the Western Cordillera, facing the Pacific, at an elevation of 12,000 feet.

The average temperature of the zone may be taken at the town of Tarma (9,800 feet).

The rainfall is very slight, probably not exceeding 15 inches per annum. This, however, could only be judged

from the flora, as no accurate data could be obtained. An exception might be made with regard to the rainfall at an elevation of above 12,000 feet, where it would seem to be heavier than at a lower altitude in the neighbourhood of Tarma.

The atmosphere is bracing, and the district generally is recommended by the medical profession as an excellent health resort in cases of pulmonary complaints.

The flora native to this region is represented by such plants as are generally found in a dry climate, aided as they are by a heavy dew-fall. The existing vegetation is of a dwarf character, and is chiefly represented by such orders as Compositæ, Papilionaceæ, Onocaceæ, Liliaceæ and Amaryllidaceæ; the latter by its two species of Agave. Wherever water is applied to the land by way of irrigation, the type of flora changes, masses of beautiful Calceolarias, Geraniums, Ageratum, and Salvias, with the striking forms of Tacsonias and such-like garden plants taking the place of the usual dry country orders.

The conditions of agriculture in this region are very favourable.

The soil is rich and of easy cultivation, being of volcanic origin. So far as is possible, use is made of the small streams from the hillsides for irrigation, the root crops usually occupying the land so situated. The mode of cultivation is of the most primitive character, the old-fashioned wooden plough drawn by oxen serving all the purposes of our modern implements.

Farming operations commence during the short season of slight rains or dews, in the months of October and September; the grain ripening in May and June.

The cereals cultivated are wheat, barley and oats. The extent of land under cultivation could not be definitely ascertained; but judging from the area visited, and from information obtained, it was evident that every available acre was under crop. Making an estimate of what was seen, I should say that the cereals grown are in the proportion of two-thirds to the other crops.

The land yields well, while the grain is heavy and of good quality.

There is a considerable quantity of maize produced in this zone, more especially in the warmer elevations. Land capable of being irrigated is preferred for the cultivation. Among the food plants of the natives it holds a prominent place.

The plant has a range of altitude of from 11,000 feet to 1,200 feet, although it would seem to thrive best at about 8,000 feet. The dry climate of Peru favours the extensive cultivation of this valuable product, which forms a considerable article of trade with the mining districts.

Of the root crops, potatoes rank next in importance to cereals. The varieties are not numerous, but are excellent in quality. The far-famed potato, known to the natives as "Papa amarilla," or yellow potato, is of medium size, round, with a very thin skin, having a yellow flesh, which, when boiled, retains its distinctive colour. It commands the highest price and is much in demand. The other varieties are also very superior in quality.

The yield per acre is, in my opinion, above the average English crop; but, as with cereals, so with potatoes, no correct estimate could be obtained of the production of this district.

Araucaria esculenta.—This herbaceous perennial resembles the parsnip in foliage, and is grown in the cooler regions for the sake of its tuber-like root. It is a nutritious food plant; but, from the rather objectionable flavour it possesses—which, however, after several boilings can be removed—has only a limited demand.

"Alfalfa" (*Medicago sativa*) affords the principal pasturage. This highly nutritious perennial is largely cultivated.

It thrives best in the dry districts of Peru, the cultivation of the plant extending from an elevation of 11,500 to 3,000 feet, at which low altitude it appears to rot from excessive heat and moisture. The land is prepared as for cereals; the seed is then sown broadcast and irrigation follows. The plant, which

is about 2½ feet high, can be cut in six months after sowing, and yields as many as three excellent crops per annum.

So prolific is the growth that, without re-sowing, the plant can be depended on to produce good crops for 15 years. It could be well preserved by ensilage; but this beneficial method of storing has not yet been adopted by the people.

This district presents very favourable conditions to the rearing of cattle; and it is somewhat surprising to find that the town of Lima receives most of its supplies by steamer from Pacasmayo and elsewhere, while this district could amply meet all its demands. The cattle are in very good condition and are fed on Alfalfa and the straw of the cereals.

Communication is carried on by means of horses, mules and llamas, as pack animals.

Tarma, the seat of Government of the Junin Province is a town of considerable importance, geographically, being in direct communication with Jauja, Oroya, Cerro de Pasco, and the Chanchamayo Valley. The population, largely composed of traders, numbers from 5,000 to 6,000.

It is the centre of the religious ceremonies of the Romish Church, and possesses ordinary schools.

Tarma may be considered as a great receiving, or trading, station. To it the Chanchamayo and Vitoc Valleys send all their production of coffee, rum and coca, which are again transmitted by rail to Lima and the coast. The towns of Junin and Jauja obtain their supplies from Tarma, from whence are also obtained all the requirements of those districts. There is an open market held every day in the Plaza, where the produce of the surrounding hills is exposed for sale. With the exception of agriculture, no special industry exists.

With the development of the surrounding districts, and of the Chanchamayo and Perené Valleys, Tarma should become a town of vast importance. It has fair facilities for transport at present; but, with the extension of the railway to the town, a great impulse would be given to the general trade of the whole province.

For present requirements there appears to be sufficient labour. The native Indian, content with his lot, makes no effort to seek new fields of work. Possessing a soil so fertile, growing almost every necessity of life, he is perhaps to be excused for regarding any extra exertion as superfluous.

On enquiry of the representative of Government, however, I was informed that a supply could be obtained from the district of Jauja; and, on consultation with several merchants I found this statement to be substantiated.

The general results derived from the mode of cultivation by the natives are so satisfactory that it appears to me difficult to suggest improvement.

The natives are in full possession of the land all around this district; but I see no reason why Europeans could not, with very great advantage to themselves, enter into terms and arrange for the purchase of blocks of land.

A large and profitable industry could be introduced in the cultivation of the "Sisal Hemp" plant, which, in the neighbourhood of Ambo, is already found growing wild in this zone, and is known in that locality by the name of "Pita" (see note p. 24). As a fibre producing plant it has received very great attention in countries favourable to its growth, and from a commercial aspect is highly remunerative.

Another industry which might be taken up with advantage is that of olive growing.

With the continued diminution of the supplies of olive oil from Italy has arisen a large demand for the oil in other countries; and from the very favourable conditions prevailing in this region, I am of opinion that its introduction would prove of great value to the growers.

The climate and soil would also favour the establishment of vineyards, should a sufficient demand arise.

SEMI-TROPICAL ZONE.

Extending from Palca 8,000 feet, to Naranjal, 3,650 feet, coloured on map pink. Average temperature in shade, maximum 75°, minimum 55° F. abt.

The district extending from Tarma to Palca, the

limit of the temperate zone, is of great fertility, and is highly cultivated, giving results as gratifying as these already described.

The present road to the tropical region follows very closely the river Chanchamayo, passing the village of Acobamba, at which place there is a good highway leading to Junin and Cerro de Pasco.

There are indications here that the whole district is but the entrance to a large valley; and, as further progress is made, ample confirmation of this is obtained.

The river at Palca runs north-eastwards through high and precipitous hills which admit of but scant cultivation.

Entering the semi-tropical zone at Palca, we traverse a country so closely allied to the tropical zone lying beyond, that a detailed description of the flora, climate, and agricultural conditions generally, need but a passing reference.

Gradual signs of a change of temperature now begin to manifest themselves. The country assumes a more clothed appearance, and nature generally is indicative of a semi-tropical aspect. The atmosphere contains more moisture, and as we proceed further down the valley the climate and temperature gradually merge into those of the tropics.

The characteristic flora in this zone is what might be expected to be met with when approaching that of a truly tropical type. The following orders may be taken as representative.

The hill-country genera of Melastomaceæ, the straggling forms of Rubus, the showy Bromeliads or Echinæ and Billbergia, growing upon the branches of small trees, with an undergrowth of Commelinaceæ and other creeping plants. The forest presents as striking a transitional form as that of the climate, from the small scrub to the giant monarchs of an Amazonic forest.

Agriculture in this district loses much of its attraction when so closely allied to the tropical region beyond, which presents to the cultivator so much more favourable a scope for his efforts.

Moreover, the lay of the land passed through, being so precipitous, cultivation is much restricted.

The road which runs through the entire valley is being rapidly extended eastward, and will serve, when completed, as the outlet to the Chanchamayo and Perené Valleys. Too much importance cannot be attached to this undertaking, as by means of this route all the produce of the valleys will be transmitted to Tarma, Lima and the coast.

The gradient of the road is such as to admit of easy transit, being 5 in 100.

Any land suitable for cultivation is so limited in extent as not to merit further notice.

TROPICAL ZONE.

Coloured green on the map, extending from the Chanchamayo Valley, 3,650 feet, to the Cascades on the River Perené, 1,050 feet elevation. Temperature taken in the shade during July and August, maximum 82°, minimum 70° F. abt. Average estimated rainfall 86 inches.

The scenery in this valley, especially in the lower reaches of the semi-tropical zone, is truly magnificent. The hills are rugged and stand out in bold relief while the river bounds headlong down until a gorge of about 200 feet deep, and 50 feet in breadth is reached. Here the eye scans a long expanse of beautiful undulating land, part of which is richly cultivated, presenting a scene of activity that would gladden the heart of the most eager of agriculturists. This is known as the Chanchamayo Valley.

Rumour had led me to form very favourable opinions on the fertility of this valley, and I had anxiously awaited the opportunities of verifying for myself, at first hand, the information I had received.

Favourable as this information had been I am pleased to be able to report that I found the actual facts to warrant even more glowing descriptions of so splendid a prospect.

There; as far as the eye can reach, lie thousands of acres of the most beautiful land, suitable for all tropical products.

The study of this locality and of the cultivation is valuable, inasmuch as it furnishes an indication of what might naturally be expected, but under much more favourable conditions, from the vast stretch of land adjacent to the Perené which your Commissioners have selected.

Further, as will be observed, I have in my description of the various branches of agriculture in this region, observed first the present state of these products and their importance commercially and incorporated with them my suggestions on what, in my opinion, would prove the best means of cultivation and generally the development of the district.

I desire also that these remarks be held as applying to the land selected by the Commissioners, as I regard the Chanchamayo Valley, somewhat in the relation of an experimental garden to that rich territory beyond, which it is now proposed to take up.

The time of the year when the Commissioners visited this district was in the months of July and August, which we then learned was the dry season. This season extends from the latter end of May to the middle of October. During that period, however, there are frequent showers, and I am informed on reliable authority that the district is not subject to droughts of any great length of time. This information received corroboration by the method of cultivation adopted on all the plantations throughout the valley.

The wet season extends from the middle of October to the latter end of May.

The absence of any statistics regarding the rainfall prevents me giving accurate figures; but from my experience in the tropics, and from a careful analysis of the flora of the district, I estimate the rainfall to be not less than 75 inches, in the neighbourhood of Chanchamayo.

The extraordinary healthiness of the people, European and native, throughout this valley, may be taken as the best criterion of the salubrity of the climate. Under ordinary precautions no fear need be entertained of any attacks of malaria; and dysentery is of very rare occurrence. Compared with the climate of other tropical countries I have visited, I have no hesitation in stating that it may be regarded as one of the best.

In such a climate the flora is of the most varied and luxuriant description, and, from a purely botanical point of view, is of the greatest interest.

The flora of the Chanchamayo and Perené, districts being essentially similar, or nearly so, I have to refer the Directors to my description, under this heading, of the Perené—see p. 16.

The lands at present under cultivation are only those situated in the immediate vicinity of the river. They are more or less flat and extend down the valley for about seven miles.

Examination of the soil—a rich loam and of great depth—throughout the entire district enables me without hesitation to state that it is admirably suited to the successful cultivation of most tropical products.

There is a sufficient supply, from the surrounding hills, of water of a good quality, which could be utilized in the cultivation of rice and other plants requiring similar treatment.

Dealing with each product according to its relative importance, sugar cane here again ranks first.

The plantations throughout the valley number 16 in all, and vary in extent from 20 to 150 acres each. The variety of cane is that chiefly grown around Lima, named "Salaagore," and by its luxuriant growth, rising as it does to a height of from 8 to 10 feet, gives evidence of the fertility of the soil. The cane is capable of yielding "cuttings" 12 to 16 months after planting, and for a period of from five to seven years continues to bear profitable crops, after which period replanting is necessary. The cultivation differs from that of Lima in that no irrigation is required.

The damp climate favours a growth of cane more suited to the production of rum, for which purpose entirely it is grown; so much so, that the demand for sugar to meet the want of the people has to be obtained from Lima. The yield per acre is about 150 gallons of rum. A ready outlet for this is found in the markets of Oroya, Cerro de Pasco and Tarma, at

the rate of \$2 50 cents per arroba of 25 lb.

The cultivation of the sugar cane appears to be better understood by the estate managers than that of any product; but even here the management is deficient in agricultural knowledge, and the out-turn of sugar could be materially increased by the introduction of more profitable varieties.

More expeditious means of transit would enable sugar growers to employ more recent and economical machinery in the process of manipulation than that now in use, and would facilitate the conveyance of manure, an indispensable to successful cultivation in other sugar producing countries.

To a coffee planter, the Chanchamayo Valley and surrounding lands present a field of vast importance and may be compared to the most favourable situations in Ceylon, every condition favouring the modern cultivation of this most remunerative plant.

The Coffee Gardens here number about 100, varying in size from 8 to 30 acres in extent, and from the primitive mode of cultivation, such as the want of systematic pruning, &c., the plant would, to a Ceylon planter, be considered "Native Coffee."

It is with pleasure I have to report that, so far as my observations and investigations went, no insect pest common to this plant, or indications of *Hemileia vastatrix*, "Coffee leaf fungus" were apparent.

Up to the present the fertility of the soil has been such as to render the use of manure unnecessary; so much so, that on a visit to one of the gardens, I found the bushes laden with ripe fruit to such an extent as to cause the primary branches to break, and, to all appearance, promising a yield of from 8 to 10 cwts. per acre.

The curing of the bean is here carried out in the most primitive style, the process consisting of simply drying the berry in the heat of the sun, and thereafter ponding it, giving consequently a broken sample which presents a poor appearance.

The total yield of the Chanchamayo Valley amount to 2,500 cwts. per annum; and, as a representative instance of local value obtained, I may state that a parcel of a few cwts. grown in the valley fetched \$15 per quintal (100 lb.) at Tarma, selling again in Lima at \$23.

For the information of the Corporation, I embody a report by Messrs. Wilson, Smithett & Co., of 41, Mining Lane, London, upon a sample procured by myself in this valley, and cured as described by me. This report I consider highly satisfactory:

"LONDON, Nov. 24th, 1891.

"Dear Sir,—We have examined the sample of coffee from Peru as requested by you, and report as follows:—Fine ordinary palish green, rather small berry, uneven size, fairly well garbled, clean flavour value per cwt. 85s.—Your obedient Servants,

"WILSON, SMITHETT & Co."

They further add in a letter covering their report: "We enclose our report on it (sample) and in addition have to say, that the coffee is of a most saleable and desirable kind, and the flavour is much superior to the small imports of Peruvian growth we have already sold."

It might be here worthy of notice that on the adjacent hills I came upon a small patch of coffee growing at an elevation of 5,350 feet although I consider the cultivation could be extended to as high an altitude as 6,500 feet, judging from the climate and the character of flora found.

The advantages accruing from a systematic pruning and handling of the coffee bush do not appear to be known, or, if known, do not appear to be practised; while in the utilization of the land at command, no regard is made in planting to distances. Coffee, in fact, is allowed to grow wild; and if, as I have shown, such splendid results are already obtained—results which I can only compare to the palmiest of Ceylon days—what might be expected from an intelligent and systematic cultivation.

I am convinced that were modern methods of cultivation adopted, pulping machinery employed, adequate drying sheds erected, and speedy means of transit available, a coffee would be produced in this region of the very highest class, commanding the topmost

figure in the open market.

The production of rice is entirely in the hands of the Chola fedians, who cultivate this product on the dry lands of the valley. Under similar circumstances in the East Indies this would be termed "Hill Paddy," or hill rice.

Sowing commences with the rains in November, and reaping takes place about May, only one crop per annum being raised.

I can only speak in the highest terms regarding the rice grown, it being superior in my opinion to that known in the Bengal market as "Muttu Samba."

The price obtained in the town of La Merced is from \$12 to \$15 per quintal of 100 lb., a price I consider to be very high.

Rice and maize form the chief food stuff of the people. The extent of rice grown is scarcely sufficient to meet the local demand, and in time of deficiency the grain is obtained from the Tarma market, where it is received from the coast at slightly increased rates.

To the capabilities of the land, and to the climatic and other conditions necessary to a very extensive and regular supply of this invaluable grain, I have directed my most careful attention, and can report with the greatest confidence to the Corporation that this district and the district of the Perené offer a field in every way suited to the growth of first-class rice.

In this important cultivation there is great room for improved methods of culture. The wet system of cultivation is apparently not understood, or at all events, is not adopted here. With a good supply of water such as now exists, with lands capable of being irrigated, with the introduction from India of such varieties of the plant as will bear two crops per annum, and with modern cleaning machinery, I see no obstacle to the production of a very extensive supply. This supply would not only meet local wants, but would act as an inducement to the hill Indians to remain in the valley, a result much to be desired. Even at considerably cheaper rates, I am of opinion that the cultivation of rice could be taken up by European capitalists as a very sound investment.

The Coca plant, *Erythroxylon Coca*, is a native of this region, is found at elevations ranging from 2,000 to 4,500 feet, and is cultivated throughout this and the Vitoc Valleys chiefly for local demand. Its cultivation is chiefly in the hands of the natives, with whom it forms a considerable and indispensable article of trade.

The plant is grown in situations fully exposed to the sun's rays and is never found in a state of cultivation under shade. For the convenience of plucking, the bush is kept at a height of two feet, and only the fully developed leaves are gathered, which are dried first in the shade with a free current of air and finished off in the sun. It is packed in bales of one quintal each, and is chiefly despatched to the hill regions. The market value in Tarma is from \$22 to \$23 per quintal.

I cannot offer any suggestions on the present mode of cultivation and preparation. Those seem to be sufficient to the satisfactory production of a good growth of leaf. In view, however, of the large and increasing demand for cocaine, the active principle of the plant, I would recommend the establishment of a central factory for the extraction of this valuable alkaloid. Were this adopted I am of opinion that the cultivation would be considerably extended and that a large business would be opened up.

I might here add that in the German colony in the locality of the Pozuzo river, a factory similar to the one now recommended is already in active operation.

The extent of the cultivation of Tobacco is limited, and is entirely in the hands of the natives.

From the appearance of the plant as presently grown, and from the nature of the soil and climate, it is evident that this district is eminently suited to its growth.

The variety grown is not productive of the best results, judging from the thick, coarse ribs of the leaf. The prepared leaf is deficient in colour, which can be attributed to the indifferent curing, especially in the

process of fermentation. The tobacco, as cured here, finds a ready sale in Tarma and the hill region, at prices ranging from \$15 to \$18 per quintal.

It is evident that the curing of the leaf is not sufficiently understood, and to this cause and this only can the present limited cultivation be attributed.

I would strongly recommend the introduction of the best Hevasana and Virgiana varieties, as the leaf is in every way so well adapted to a successful industry being established.

The cultivation of Indigo was entered upon a few years ago by the more energetic planters, but owing to an inadequate knowledge of the preparation of this valuable dye stuff, the industry is now almost entirely unknown. No reason exists, in my opinion, why a remunerative industry could not be established; an opinion, verified by the fact that, even in a semi-wild state, plants are found growing to a height of 2 feet.

Previous attempts at the cultivation of cotton have not proved very satisfactory; but this can, in a great measure be attributed to a too heavy rainfall. From specimens of the plant found in the neighbourhood of the houses, it is apparent that the soil is capable of raising a very healthy growth. The further cultivation of this plant in the Obanchamayo Valley, however, is not recommended by me.

Maize here, as throughout the hill region, occupies an important place as an article of food of the people. The natives cultivate the grain in small patches around their houses, and from the growth of the plant I am enabled to state that an extensive supply could be raised if required.

This valley has at present only one outlet, namely, by way of Huncapitana and Tarma.

The road now in course of construction is expected to be completed in May, 1892, when it will afford better security for the safe transmission of the produce, thus supplying a great desideratum of the Obanchamayo planter.

All produce is despatched by mule and donkey to merchants in Tarma, who in return send back other goods needed in the district. As indicative of the freight on articles of commerce between this district and Lima, I may here state that coffee is conveyed to that town at the rate of \$3.40 cents per quintal.

Judging by the number of estates in the valley and from their several requirements, I estimate the number of laborers at about 5,000. These men are drafted from the hill regions around Tarma, and (as laborers) are active, industrious and persevering in their habits. The estate managers speak highly of their general ability and easy management.

The women do not work on the estates, as might be expected; but I have no doubt they would be available for a certain class of work. The men receive as wages 30 to 45 cents of a sol each per diem, with sleeping accommodation for themselves, their wives and families.

The boys are engaged at the rate of 20 cents per diem, and are found to be very useful. This important subject, in its more general aspect, has received from me further treatment elsewhere.

Having thus fully described the whole of the cultivated part of the Obanchamayo Valley, its products, its capabilities, and its probable future under better methods of cultivation and with other improvements, it may prove of interest to the Corporation if some reference be made to that portion of the valley lying between La Merced and San Luis, at the junction of the River Pancartambo.

This stretch of country, a distance of 18 to 20 miles, I was informed was not available for colonisation by the Corporation, and in view of this fact, I did not devote the same attention to the land (beyond noting its outstanding features) that would otherwise have received careful explanation. I am in a position, however, after giving due consideration to the interests of the Corporation with special reference to the Perené district to advise that should opportunities present themselves the Corporation should not hesitate to extend their territory by acquiring the land referred to.

That a direct connection with La Merced will be of great value to the Corporation is in my opinion an

undisputable fact, for I consider that when the Perené district become the field of a busy agricultural industry, the town of La Merced with the connection to San Luis will then become an important trading centre.

This portion of the valley is under no system of cultivation, being in fact still in a state of natural wildness.

The river banks, unlike the upper portion of the valley, rise rather abruptly from the water to an average height of 250 feet, where there exists a large expanse of rich undulating land presenting similarly favourable conditions to those of the district already described and in my opinion only awaiting development by the skilled planter.

San Luis, at which place is a convent of six years' standing, is situated on the banks of the Paucartambo river, about 7 miles above the junction of that river with the Chanchamayo, and is a district possessing many excellent conditions favourable to tropical agriculture; giving, however, only an indication of that vast expanse of land selected by your Commissioners upon which it is now my intention to report.

Leaving San Luis and crossing the Paucartambo by the suspension bridge erected by the Government of Peru, the land now entered upon has, I understand, been selected by the late expedition of Basque farmers, which territory has received my attention in a separate report. This block of land as shown on my map accompanying this report is bounded on the East by the river Eneuo, from which point I would now direct your attention.

THE PERENÉ VALLEY.

Land selected by the Commissioners as indicated on the map extending from the river Eneuo (1,700 feet) to the Cascades (1,050 feet elevation) and to a distance of 10 leagues or 30 miles on either side of the Perené.

Average temperature taken in the shade during the month of August, maximum 87°, minimum 70°, Fahr. Average estimated rainfall 86 inches.

In treating on the region of the Perené it is my intention to adopt the method hitherto observed in my report; but I may be permitted in the first place to make some reference to the route taken by the Commissioners, and otherwise to summarise the conditions under which the journey was accomplished.

Arriving on the night of the 27th July, at the junction of the rivers Perené and Eneuo, it was decided we should remain until arrangements could be made with the Chauchoo Indians for our trip down the river. After repeated disappointments during a stay of eight days in the house of an Indian King, Chocery by name, we were at last provided with four "Balsas" or rafts, upon which our entire Company, consisting of 15 persons, embarked on a venturesome voyage to the Cascades. The downward journey occupied two days and the return six days.

The Perené river is of considerable importance, having many tributaries, some of which, arising at considerable distances inland, issue from such districts as the Chanchamayo, Acobamba and Paucartambo valleys, as also from the regions drained by the Colorado, Eneuo and Pichana rivers. The volume of water is large and the quality fairly good.

The average breadth is about 75 yards, although in some places it extends to about 120 yards.

The average depth I compute to be about 3½ feet, while the average rate of speed I reckon to be about 3 to 3½ miles per hour, more or less affected according to the contracted or expanded area between its banks.

From the Eneuo the river's course runs first east, then south-east, and afterwards east as far as the Cascades, at which point it turns almost due north for a short distance.

The river in its course from the Eneuo to the Cascades, a district of 40 miles, embraces some of the finest scenery I have yet witnessed, the banks being clothed to the water edge with luxuriant foliage, while the landscape of undulating land is much relieved by an occasional tree in full flower, making the whole scene one of unsurpassed beauty and grandeur.

Leaving the Eneuo, and for a distance of about 10 miles down, the general tendency of the banks is precipitous, the promontories rising to a height of

about 250 feet; but below this and to within four miles of the Cascades, the character of the banks resembles very closely the beautiful slopes of the Chanchamayo in their most favourable situations.

While there are several smaller steamers running into the Perené, those of more importance are respectively the Pichana, Quimiri and Ipuji.

It is of importance to know that to all appearance the river does not overflow the banks to any extent disadvantageous to probable cultivation.

As may be imagined from the wild country through which we passed, many difficulties had to be encountered and overcome; but the balsas enable me to make several separate excursions into the interior where I had opportunities of examining minutely the flora, soil, and land generally, and from these I gathered my information and facts.

It is necessary to explain here that we were unable to thoroughly explore the Cascades in consequence of the Indians having decomposed up the river with our "Balsas" and provisions while we were in the act of inspecting the neighbourhood. That portion of the Cascades visited was, however, sufficient to my purposes, and convinced me that this part of the river is the only obstacle to free navigation, and that in its present condition it would certainly be a barrier to an outlet by water eastwards. I am of opinion, however, that a roadway or tramway could be laid down, conveying, if necessary, the produce to a navigable portion further down the river, although railway communication from this district via Tarma to the coast would be a more efficient system.

Wet season extending from latter end of October to middle of June; dry weather from June to October.

Having treated at some considerable length upon the climate of this zone, taking the Chanchamayo Valley as representative of what exists over all, more or less changed according to elevations and rainfall, I may but summarise these outstanding conditions with special application to this district.

The climate is certainly tropical, but has none of those unhealthy indications pertaining to most tropical countries. A better estimate may be formed of the climate when I state that from an experience of the tropics extending over 10 years, I can positively state that it surpasses even the climate of Ceylon at such parts as are at similar altitudes.

The Indians who inhabit this region are fit and typical representatives of the salubrity of the climate. They show no signs of malaria or other tropical complaints, and are of exceptionally healthy constitution and manly physique, and live to a considerable old age. The atmosphere is particularly free of any objectionable odours arising from stagnant matter; and while, no doubt, a European may, through unguarded and reckless exposure, induce an attack of fever, it is my unbiased and firm conviction, supported by my own experiences, that the whole region offers such climatic conditions as would amply justify my recommending the appointment of European Managers over any agricultural enterprise.

The average rainfall I estimate at 86 inches per annum, a figure which, from the type of flora found, I would say is often exceeded; the most easterly limit being about 10 inches in excess of this estimate.

Another important feature of the climate of this region, and one favourable to a uniform degree of cultivation, is that, at no time does a condition approaching to severe drought occur, although like every district visited it has its periods of wet and dry weather. The Chauchoo Indians, from whom I repeatedly elicited such facts, assured me of this; but I desired from personal knowledge to verify these statements, and on examination of the flora found sufficient confirmation in the great variety of Lycopodiaceous plants growing upon exposed rocky situations supported only by a thin film of soil. These, I need hardly state, could not exist unless under such circumstances.

Of almost equal importance to the latter is the fact that the district is not wind blown.

I trust that I have conclusively shown from facts gathered, that the climate is one exceptionally favour-

able to the establishment of tropical plantations, and suited in all respects to the conditions required for a large European settlement.

To a botanist the flora of the Perené Valley is of the deepest interest, and in some respects unique. Here are met the giant monarchs of an Amazonic forest, with an abundance of kinds of parasitical growth.

Everything impresses the mind with the fact that here nature is indeed primeval. But although interesting in this botanical sense, and possessing a value peculiarly its own, the interests of the Corporation demand from me more practical treatment.

The variety of flora, but especially that of the undergrowth, is of a most varied and luxuriant description, presenting a scene of great richness.

Here is the home of most of the species of Anthurium, Philodendron, Caladium, Peperomia, Dieborisandra, and dwarf Palms, with the beautiful tropical species of Begonia, the striking leaved and flowered Gesneraceous plants, and the terrestrial Orchids, with their epiphytal allies, such as *Oncidium*, *Epidendrum*, *Cattleya*, &c., &c., all lending a charming colour to the deep green surroundings of a tropical forest. Here also the *Sotaguella*, forming a carpet-like growth, are represented by seven species, some of which were quite new to me; while the beautiful and feather-like tree ferns which here abound grace this really magnificent display of nature. Never has it been my privilege to witness such a collection of horticultural rarities.

The most prominent feature which at once arrests the eye is the enormous dimensions of some of the larger specimens of tree life. To render these of commercial value, speedy and economical means of transport are absolutely necessary; and with such beautiful and valuable timber trees so adaptable to the various requirements of trade, it would seem a positive waste to fell indiscriminately the whole jungle in opening up this region.

The following are the most conspicuous trees of commercial value which I noted during my limited opportunities:—

The "Black Walnut" (*Juglans nigra*): This tree the wood of which is so valuable, is most commonly met with at elevations ranging from 2,000 to 4,000 feet. Specimens were found which gave a diameter of 49 inches, with a column-like stem of about 75 feet.

The "Toon" (*Calyptra odorata*) is very common throughout this district at similar altitudes, and attains almost as large dimensions; one tree I happened to measure giving a diameter of 36 inches, with a stem 60 to 65 feet high. This tree, so allied to the mahogany, provides a timber used for all light work, and has the advantage of not warping when cut. This is the wood principally used in Cuba and South America generally in the making of the well-known dark coloured cigar boxes, and it could be largely employed here for such purposes.

A species of wist I take to be *Facaranda brasiliensis* commonly known as "Koso Wood," having a beautiful grain, was also found. This would be highly prized for choice cabinet work.

Equal in value as timber for building purposes is the *Calophyllum Calaba* and the *Mimosa elata* while others of less value, but equally common, are a very high species of *Erythrina* with its conspicuous red flowers, and the "Sand Box" tree (*Itura crepitans*) with its huge trunk.

Cacao was found at elevations ranging from 1,050 feet to 2,700 feet, and extending all along the valley from Chanchamayo to the Casendes. Trees were found 50 feet high, with a diameter of 18 inches at 3 feet above ground, and generally found growing under shade. So far as I could ascertain, there is found wild only one variety, the fruit of which, when immature, is of a greenish colour, turning when fully ripe into an orange yellow.

The pods, which are about 8 inches long, are deeply fluted or ribbed, and contain from 27 to 30 seeds of a triangular shape and of deep rose or purple colour. The variety is one of the most superior of the Forastero class so much in demand in Ceylon

The crop would seem to ripen in April or May. In no case did I find the plant cultivated. The natives however, collect the beans and prepare a sort of cocoa from them, and a kind of vinegar from the husk.

In this valley I found the Vanilla plant growing wild, and in no case under cultivation.

Within the elevations 1,500 and 3,000 feet, the valuable plant seems to thrive best. Three varieties were found, one with leaves 12 to 14 inches long bearing triangular pods 14 inches long, having a strong aroma; one with smaller leaves with round pods 12 inches long, equally strong in flavour—the plant (*Vanilla planifolia*) in general cultivation throughout the tropics; another with thin pods with little or no aroma.

While yet green, the natives collect the pods and cure them by simple exposure to the sun resulting in the production of a very poor article indeed.

The plant is very common throughout the entire valley, and the growth is exceptionally good.

Whereas in most countries where this plant is cultivated, fertilization is artificial, the flowers here are naturally fertilized.

This herbaceous plant (*Cephalis ipecacuanha*) was found in the low damp shady forests near San Luis, but not in quantity. I have every reason, however, to expect that on a more diligent search being made in similar situations it might be found in quantities sufficiently large to attract attention with a view to exportation.

Of a creeping habit, this tubaceous plant grows to a height of about 12 inches, and produces long wiry annulated roots, the portion of the plant used.

The valuable properties of this important drug do not seem to be recognised by the natives.

Cinchona.—Of this valuable plant there would appear to be three species peculiar to the valley of the Obanch-mayo river; but as it so happened, neither of these were found in flower. I had, therefore, only the foliage of these plants by which I could define the exact species, and consequently have had considerable difficulty in naming them. From the foliage, however, I would suppose them to be *C. micrantha*, *C. laevis*, and another unknown. The bark of these plants, however, on analysis proved to be poor in alkaloids compared with the more valuable species found further south.

The plants found were quite 50 feet in height and are very common indeed.

On more searching exploration of this vast territory, I have every reason to expect that the more profitable species would be found.

Coca.—This valuable plant (*Erythroxylon Coca*) was found wild at from 2,000 to 4,800 feet elevation, and, as a cultivated plant, in the neighbourhood of the Indians' houses. The leaves are only gathered for local consumption.

Sarsaparilla (*Smilax officinalis*).—This drug of less importance was found growing wild, generally in the warmer regions of the river, in free or sandy soil. The roots, which are the commercial part of the plant, were of exceptionally good size and could be exported in large quantities.

Tobacco.—In the neighbourhood of the houses of the Chanchuco Indians, this plant is found in a semi-wild state, and is chiefly collected by them for the nicotine which is used, along with coca, in their masticatory. This extract is obtained by a process of pounding the leaves, previously partly cured, when water is applied; after which fermentation takes place, the whole being strained through a perforated ground.

ARNATTO.—The product of a plant (*Bixa orellana*) common throughout the whole valley below an elevation of 4,000 feet. The dye is made from the seed and is used by the Chanchuco Indians in colouring their bodies.

It is largely grown in the East Indies, whence England and the Continent receive their supplies.

As a colouring matter for butter and cheese it is sold in Europe from 3d to 6d per pound.

Logwood (*Hematoxylon campechianum*).—In the act of clearing the jungle for plantations it would, in my

opinion, be advisable to preserve this tree for the sake of its properties as a dye-wood which is largely imported into England from the West Indies. The tree is chiefly found in the Chanchamayo and upper end of the Perené Valleys.

VEGETABLE IVORY.—This is the product of a palm (*Phytelephas macrocarpa*) found very abundantly on the slopes of the hills at an elevation of from 4,500 feet to the neighbourhood of the Casacaca.

It may be easily distinguished by the peculiar black round spicy fruit, which encloses seeds of about the size of an ordinary peach. The value of this product is not recognised by the Indians of the Perené, although I am informed that large quantities are shipped to Para from the neighbourhood of the Ucayal River.

The seeds are largely exported to England and the Continent for the purpose of making studs, buttons, and such like articles, and are sold at prices ranging from £16 to £20 per ton. Large quantities of these seeds could be collected.

VEGETABLE WAX.—This is the product of a palm (*Copernicia cerifera*) commonly known as "Carnauba Palm," which is found growing extensively on the higher reaches of the valley at an elevation of about 4,200 feet. The plant attains a height of about 20 feet, and can be distinguished by the ashy grey wax powder found more especially upon surface of the young foliage.

This wax, although not collected in this valley, is largely exported from Brazil to Europe, where it is chiefly used in the manufacture of candles and for like purposes.

DIU DIU.—This hard-wooded tree (*Cesalpinia coriaria*) of medium size is common throughout the valley, at about 3,000 feet elevation. The strangely twisted pod of this tree is a powerful astringent, and is exported from the West Indies to England and to the United States for tanning purposes. This article could be used on the coast, not shipped to England.

RUBBER (*Hevea brasiliensis*).—This is the tree the rubber of which is so highly valued, and is imported into England from the neighbourhood of the tributaries of the Amazon.

From personal observations I cannot report upon it as growing in large numbers in any of the districts visited by me, although specimens were found in the region of the Perené at 1,100 feet elevation. It is important, however, to note that, on repeated enquiries on my part from individuals who had visited the rubber producing localities, I was assured that the supply of this product is within reasonable distances of the Perené Valley, being largely found in the locality of the rivers Pichis, Pachica and Ucayal.

With the destruction and ultimate death of all rubber yielding plants under the present system of collecting that product in the Amazonian region has arisen the necessity of providing for future demands, and already extensive plantations are under cultivation in Oeylon and elsewhere.

In view of this fact I would strongly recommend the planting-up of extensive tracts of land with this product—one of the most remunerative in tropical agriculture—the commercial value of which is certainly on the increase.

YUCCA.—Yucca, maize, sweet potatoes, the nut of a palm (*Euterpe edulis*) with fish, form almost the only articles of food, and upon these the natives manage to build up a strong, healthy and muscular system. "Yucca" (*Manihot utilisima*) holds the same place as a food to the Indian as does rice to the Madraso. It is very abundant over the Chanchamayo and Perené regions, growing to perfection in the gardens of the natives, the roots or yams attaining a large size. These when properly boiled form an excellent vegetable, and are quite palatable to the taste of a European. They were the chief articles of diet during my expedition into the interior.

The plant is cultivated at elevations of 5,000 feet and under. A period of six to eight months elapses before the yams attain to maturity.

MAIZE.—This grain grows equally well in this district, generally round the huts of the natives. A sufficient supply is always maintained for their own wants.

RICE.—Although the land is extremely suitable for

the cultivation of rice, that grain is not grown throughout the valley.

The general configuration of the whole of this great extent of country is, for the purposes of tropical agriculture, of the finest possible description.

Nothing in my opinion could surpass the suitability of the soil, the lay of land, and the climatic conditions generally, to the most successful of cultivations.

From the Great Andean range of mountains, rising to an elevation, of over 22,000 feet, the general tendency and slope of the whole country is one continuous fall, broken here and there with hills rising above the general elevation. This characteristic feature extends throughout the entire valley of the Perené, resulting in the formation of a valuable tropical region.

With so extensive a stretch of country, I need hardly point out, there must be of necessity a variety of situations, each in its own way more adapted to a particular branch of agriculture; and in the location of the different products depends much of success or otherwise of any probable enterprise. I have much pleasure, therefore, in assuring the Corporation that there are here present the conditions required to meet the successful cultivation of the products I now intend enumerating.

From its commercial importance I am of opinion that coffee might form one of the chief products of the Perené Valley; and in support of this view I have only to refer the Directors to the most satisfactory condition of this industry in the Chanchamayo Valley, already reported upon by me; conditions which, I believe, would find a parallel in this region.

Judging from altitude (and consequently climate) as the chief factor in the production of a high class coffee, the Perené Valley offers most favourable conditions. Extensive tracts of land can be obtained for this product at an elevation of between 3,000 and 5,500 or 6,000 feet.

From the fact that cocoa is here found growing wild, presenting a luxuriance of growth such as the most favoured countries engaged in its cultivation cannot offer, and, from a personal knowledge of the requirements of the most profitable varieties, I can report that the large extent of land within the elevations of from 2,700 to 1,050 feet includes a suitable area for the cultivation of this equally remunerative product.

The cultivation of the sugar cane being here independent of irrigation, the restriction of the area suitable to its growth is not so limited. In the more tropical parts it would, therefore, prove another and not less profitable product to those enumerated.

In treating of the three preceding products, it will have been observed that they each occupy separate or distinct ranges of elevation, and consequently divisions of the whole area; the elevated or cooler region being better adapted to coffee; the intermediate or warmer district for cocoa; and the level or more tropical land for sugar cane. Embraced in these three divisions are the conditions required by a number of economic plants; and I would here enumerate these, which, with the products found wild, are capable of being cultivated with equally satisfactory results.

Tea, cardamoms (both varieties) and cinchona; rubber, pepper, nutmeg, clove, allspice, gambier, indigo, Liberian coffee, tobacco, and manilla hemp; with rice, coconuts, and the area nut.

To these I would add the cola nut plant, a product which is now attracting considerable attention, and which requires the warm damp valleys, or similar conditions to that of cocoa.

That an efficient and expeditious means of transport to the great markets of the world is absolutely necessary to the successful development of any country is well known.

In the present railway system, extending, practically speaking, to Oroya, the interior regions of Peru will have an outlet for their general produce; but I am of opinion that the operations which are already engaged in around Tarma, the Chanchamayo Valley, and, still further the more extensive industries which the opening up of the new territory will necessarily create would warrant my recommending the Directors to extend

that communication still further into the interior.

While, no doubt, the outlet by the Perené river which is in direct communication with the Amazon, may in future years have a certain attraction to traders should the natural obstacles of this river be overcome there can be no doubt that in the railway lies the more expeditious of routes.

When the Perené Valley comes thoroughly under cultivation the volume of trade which must pass to the coast will be considerable. It is, therefore, to the interests of the Corporation to provide a suitable outlet.

The configuration of the land in the region of the Perené is of such a character as to afford an easy approach; roads or tram lines could without much difficulty be constructed, the present pathway being of no account.

Given a suitable country for development, the question of greatest importance to the agriculturist is that of labour.

This fact, which has so universal an application, finds no exception in Peru.

Labour may be regarded as the only obstacle to progress of South America in general, as well as of all the West Indian Colonies.

The Cholo or Hill Indians of Peru are few in number in comparison to the great extent of hill country they occupy. Rather small in stature, but of good physique, they are strong, and, in my opinion, capable of being taught to work in a more thorough manner, and with a greater regard to the interests of the capitalists than the present system would seem to favour.

It is my impression that the difficulty of the labour question, even taking the present limited supply, is in no small measure to be attributed to the fact that the native so easily acquires his means of subsistence from the fertile soil, and lives in a climate which makes everything so conducive to a comfortable life.

That the present supply of labour would be inadequate to extensive operation is evident from the scarcity which exists in those districts already under cultivation.

With such circumstances as these before me, I devoted particular attention to the possibilities of the country providing a food supply sufficient to a large immigration of foreign labour, but more especially Tamil or Chinese, and I have much pleasure in assuring the Corporation that there is nothing either in climate or otherwise to prevent a large and constant supply of the finest quality of rice and other necessaries being produced in the tropical districts.

In support of this, I have only to refer the Directors to those portions of my report which deal with these special cultivations. Moreover, I was informed by numbers of the German colony in the neighbourhood of the Pezuzo River that the cultivation of rice in that district was capable of considerable extension in the event of a demand arising for that article.

From my experience of foreign, but more especially Tamil, labour, and with a knowledge of the stipulations formulated in the regulation of emigration, I am convinced, so far as the actual conditions of life in the interior are concerned, that there is nothing to prevent the required articles of agreement being fully complied with.

From the very suitable climate, the certainty of an excellent food supply and other indications enumerated by me, no hindrance in my opinion need be expected in the settlement of this—the most necessary—element in the success of this important undertaking.

To the successful development of the extensive land enterprises of the Peruvian Corporation, it is my firm conviction that a central agricultural garden is of the first importance.

That experimental gardens have been invaluable to our Colonies in the furtherance of all agricultural and commercial interests has been proved by results so apparent as not to require further mention here.

I would take the liberty therefore of directing the attention of the Corporation to the importance of organizing such an establishment in the interior of Peru

should the region just reported upon be taken up.

It would be the object of such an establishment to study the interests of the Corporation in general from an agricultural point of view, by the introduction of such plants as would prove of commercial interest to the tropical planter and hill farmer, keeping up a supply of such plants as were likely to be in demand. Periodical reports upon the condition of the planting enterprise, and also any suggestions regarding the further development of the Corporation's lands could be made; while with a view to supplying their wants, the requirements of the home and continental markets could be studied.

Being under the impression that such an establishment might be organised at some future date, I took advantage of my stay of two days at Jamaica, en route to England, where I had the pleasure of interviewing Mr. W. Fawcett, the Director of the Botanic Garden, with a view to his support in the introduction of those economic plants which might prove of value in Peru, and in exchange for which he would receive any plants or seeds of botanical or commercial value found in the regions of the Corporation's lands, and I have great pleasure in informing the Directors of the hearty co-operation offered by the Director of that establishment.

I might here add that this Botanic garden is thoroughly equipped in the economic plants of the East Indies and elsewhere, at the same time being free of any traces of the coffee leaf disease so prevalent in the East.

I would impress upon the Corporation the importance of dealing only with this Botanical Station in preference to others throughout the West Indies. Moreover, it has appeared expedient to the Government of Jamaica to enact a minute prohibiting the further introduction of seeds or plants from such colonies as are known to be suffering from the ravages of *Hemileia vastatrix*.

I am confident, moreover, of the support that such an establishment would have from the authorities of the Royal Gardens, Kew; more especially in the identification of rare plants and rendered in the valuation of any new economic product which might be found in that rich but as yet unexplored region taken up by the Corporation.

The maintenance of such an Institution, when once organised, would be of small account compared to the immense benefits accruing therefrom, while the income derived from the sale of economic plants would materially lessen the yearly expenditure and assist in the purchase of those plants and seeds required to further and improve the existing cultivations.

In concluding this report on the extensive tract of land selected by your Commissioners, it gives me very great pleasure in congratulating the Directors of the Peruvian Corporation on the excellent prospects which the careful development of this region will ensure.

With a climate of such salubrity and adaptability to a European settlement, a soil of exceptional fertility, an immunity from most of the insect and parasitical plant pests, the tropical products found, with an adaptability to the introduction of other economic plants, which have proved so important to the development of other countries, together with the opening up of the country by means of improved transit, I have every confidence in the future prosperity of tropical Peru.

I only hope that at some future date it may be my pleasure to know that many of my practical suggestions and other matter contained in my report have proved of value to settlers, and to the Directors of the Peruvian Corporation.

HUANUCO DIVISION.

The Representatives of the Corporation at Lima had advised the Commissioners to visit the famous coffee producing district of Huanuco with the object of selecting land suitable to this cultivation. In this portion of my report attention will be given to the products of the districts passed en route, and especially of the prospects at Huanuco.

Taking Tarma as a centre, the Commissioners left

that district by the road leading off at Acobamba. My description of the agricultural conditions around Tarma and in the temperate zone will serve as fully embracing in every particular the locality as far as Junin.

This village (12,000 feet elevation) is situated in the middle of the large pampa, or plain, known as the Junin Pampa, and serves as a place of resting and trade between the smaller hamlets in the hill districts. Around Junin sheep farming is the chief source of industry. The animals are in good condition, the pasturage is abundant, and is capable of maintaining large flocks. An attempt at wheat growing, chiefly for the sake of the straw, is not a success.

From this point until Cerro de Pasco is reached, there is a general ascent with a corresponding diminution in the productiveness of the land. Cerro de Pasco, the centre of the mining region, is a town of 5,000 to 6,000 inhabitants. There are about 400 mines in the district. The ore is reputed very rich, the lower workings being the much more valuable.

A considerable trade is done with Chanchamayo in rum and coca; the former being sold at \$4 per arroba of 25 lb.

Labour here is more plentiful, and the average pay of each man is 70 cents of a sol per diem.

A rich seam of coal is found here and, being accessible from the surface, operations are conducted at a small cost.

There is a decided and general request on the part of the inhabitants for some more expeditious mode of transit than at present exists; and it is my opinion that the Corporation could with advantage to themselves extend their railway system to this town, and thus tap all the traffic to and from the mines.

This mining district extends about midway to Huariaca at which point the country begins to assume an agricultural appearance similar in every way to Tarma.

The valley is rich in the production of temperate cereals. The land in the immediate vicinity of the valley is steep, while the soil is of a rich loam, an admixture disintegrated rock. The crops grown here compare very favourably with the Tarma district.

Not until within ten miles of a village, Ambo by name, is there any alteration in the general character of the country.

No accurate or reliable data could be obtained regarding the output of any of the crops, with the exception of a district between Cerro de Pasco and Huariaca, where some 25,000 quintals of potatoes are produced after supplying the needs of the mountain towns.

Leaving Ambo, the very fertile valley leading into Huanuco is entered upon. Here the arable land on either side of the little stream is fully occupied by agriculturists. The valley is about 15 miles long by, in some places, 2 miles wide. The climate resembles that of Tarma but, being a lower altitude, the temperature is higher.

The flora of the valley, especially on the precipitous hills on either side, is of a very dry type, and is represented by such plants as Cactaceae, of which the only plant of economic value is the *Opuntia cochinellifera*, on which the cochineal insect lives. It was here, also, that I found the species *Agave* which is known to the Spanish as "Pita," (and which on my return to England I identified as *Agave rigida*, var. *sisalana*), or what is known to commerce as "Sisal Hemp." This is a very valuable fibre plant, and is at present receiving special attention in tropical countries. The plant is found wild here, and is used as a fence round small properties.

The natives use the fibre for binding purposes, but do not know the value of it commercially.

The plant can be distinguished by its long green leaves with a uniform breadth except in the middle of the leaf, which may be one to two inches broader; no marginal spines; only the large black terminal spine.

The plant could be largely planted throughout this zone, and as will have been noticed, is highly recommended to the dry zone about Tarma.

All agricultural pursuits throughout the valley are carried on by means of irrigation which the stream affords. The surrounding hills are very dry, and are only

ospable of being cultivated where water is obtainable. HUANUCO.—The town stands at the foot of the valley, and has a population of 3,000 to 4,000, among whom are a number of German merchants having interests in the Pozuzo district.

The chief products cultivated around Huanuco are sugar cane, coffee, cotton, maize, with English vegetables and fruit trees, such as apples, pears, peaches, chirimoya, and Luciona.

Sugar cane is grown for the sake of rum, which commands a high price here, being sold at \$3.50 per arroba, and is chiefly despatched to Cerro de Pasco and the villages on the hills.

I am of opinion that coffee could not be grown other than by means of irrigation. That produced is of very fine quality, and is chiefly despatched to Lima by way of Cerro de Pasco.

The other products are of minor importance, being grown only for local consumption.

All the available land at Huanuco is already fully under cultivation. The Corporation, therefore, need not expect any territory for development there.

While at Huanuco, I was pleased to have an opportunity of interviewing two of the leading settlers in the German colony. Perhaps it would be better to give the answers elicited to questions.

Mr. Luis Egg said:—

"The German settlement is made up of 90 to 95 families, or numbering 500 people. The colony is situated at the junction of the Pozuzo and Huanacabamba rivers, and is known as the Colony Alemana.

"The Colony is fifty miles S. E. of Huanuco and is reached by a very bad road or path. The district is at about 1,500 feet to 2,500 feet elevation. There is no forest land between Huanuco and the Settlement until about five miles distant from the Colony. The chief cultivations are coffee, cocoa and sugar-cane, with a little cacao.* The labour (chiefly Chola Indians) is scarce; payment is made at the rate of 30 cents of a sol per day, with a supply of coca. There is ample land available between the Mayo and Pozuzo rivers for colonization, which territory is about 1,500 feet elevation.

"There is a distance of ten leagues or thirty miles between the junction of the Pozuzo with the Palcazu to the river Pachitea. There is a general desire to have an outlet by the Palcazu and not by way of Huanuco.

"There is about 1,000 cwt. of coffee sent from the district to Huanuco by mule, besides tobacco, cocoa, and maize. We would be quite content if we had an outlet, schools, and a market for the produce, which could be considerably increased if required. The local market is supplied with rice, while the cultivation could be considerably increased if a market were found."

On the return journey after leaving Huanuco, Cerro de Pasco was reached, whence a road leading west of the Junio Lake or laguna was taken.

On reaching the small village of Banios (13,800 feet) a remarkable hot spring was noticed, the water of which was clear, and registered a temperature of 129° Fahr., and was a reputed cure for all skin diseases.

From a sample of the water taken to England, I now embody an analysis by Messrs. Savory and Moor, 143, New Bond Street, London.

"London, November 19th, 1891."
"... No arsenic or other poisonous metals were found."

"The most was made of the very small quantity of water at our disposal, and the following component parts were determined:—

Calcium	...	(parts per million)	347.5
Magnesium	74.3
Chlorine	630.0
Sulphuric Acid	1484.0
Nitrogen (as Nitrates)	1.6
Sodium present, quantity not determined	
Silica	
Carbonic Acid	
Total solid	4075.0
Total hardness	grains per gal.	Clark's scale	77.0

* So in original; but either "cocoa" or "caca" should be "coca."—ED, T. A.

"The chief characteristics of the water are its alkalinity, the presence of sulphuretted hydrogen, and the large proportion of salts, chiefly sulphates, carbonates and chlorides of calcium (lime), magnesium and sodium.

The remaining part of this road passes through a district resembling Cerro de Paseo, and ultimately leads into Chicla.

From this point the journey was completed *via* rail to Lima, where I arrived on 28th October, 1891.

I am, Gentlemen,
Your obedient Servant,
P. D. G. CLARK.

APPENDIX.

The tribe inhabiting the regions of the River Perené and known as the Campas or Chanchoo Indians, are of a migratory inclination.

They are a healthy race, of medium height, strong muscular build, and of a coffee-brown colour. They live in groups of two to three families in huts, constructed of palm leaves.

Their chief occupation is that of catching fish, with which the river abounds. This is accomplished by means of lines with primitive hooks. They are also expert in hunting wild animals and shooting birds by means of bow and arrow, the region affording ample scope.

Trading, so far as was carried on by us, was paid in kind, the Peruvian currency being valueless.

P. D. G. C.

THE PLANTING COMMISSION TO PERU.*

The report of Messrs. Ross and Sinclair has not yet appeared; but these gentlemen have been forestalled in rather a curious way by their Assistant and subordinate, Mr. P. D. G. Clark of Peradeniya Gardens, who came back some weeks in advance of them, according to one story because the Commissioners had no further use for his services. However, Mr. Clark has with the aid (it is rumoured of a clever relative on the Scottish press, as also) of the Peruvian Corporation office prepared and published a report on the work and results of the Commission which if not "exhaustive," was certainly, with justification, designated by the Corporation Manager in handing me a copy as both "very able and interesting." As six copies of this Report were forwarded by last mail or the one before, direct to Mr. Clark (who left for Ceylon the day the Commissioners landed from Peru), no doubt you as well as other local editors have seen the document by this time and the elaborate map with routes, with which the Corporation accompanied it. The first thing that staggered me was the "title page" which gives Mr. Clark (who is not even No. 2 on Dr. Trimen's staff) the designation of "Curator, Royal Botanic Gardens, Peradeniya Ceylon." As I find that Mr. Clark has not added this, or any, designation to his name in signing his Report, I put this down as a blunder of the printer or publisher; but on enquiry I learn that the Corporation staff hold Mr. Clark responsible for the title page as for the rest of the printed matter, that in fact he either called himself, or allowed himself to be called, "Curator." This may be ignorance, but it is rather an awkward slip; and I have ventured to tell those concerned that they could easily see Mr. Clark's official position in a "Colonial Office List" or "Ceylon Directory." I should never for a moment have publicly found fault with Mr. Clark for what may be an inadvertent blunder, but for what follows in the general tenor of his Report which, I feel sure, must be both astonishing and amusing to his friends and acquaintances, no less than to his superiors, in Ceylon. For, this Report is couched in language which could only be justified if Mr. Clark were at

the head of the Commission, and had he an experience as a planter and director of labour wider than even Ceylon can afford, and certainly far wider than he could have gained in the Peradeniya Gardens and neighbourhood! The opening paragraph and that on "Labour" may be taken as illustrations. The sensible as well as shrewd idea, to judge of the rainfall and dew of the different districts in a country, in which no meteorological observations were available, by the appearance and character of the vegetation was, I believe, entirely Mr. Sinclair's, though no acknowledgment is made to him, nor his name nor that of Mr. Ross once mentioned in the report before me. The latter indeed has been even more unhandsonely treated; for it was his idea to give some notice of hot springs at Banios and he himself bottled some of the water for analysis and report, entrusting the carriage of it to the Assi-taut, with the intention no doubt of dealing with the matter when he got home. Unfortunately, though Mr. Clark thus largely benefited by his association in a great portion of the journey with two such experienced planters as the Commissioners, he has not kept free of blunders; for I understand that his criticism of "sugar" cultivation is considered to be egregiously out of place; the sugar planters in Peru being better able to teach, than to be taught by, anyone from Ceylon. In their wonderfully dry climate they can even produce good sugar at as low a rate a price as 5s 6d a cwt., which sells at Liverpool from 13s to 18s per cwt. in bulk; and there are plantations (some of them under Scotchmen from Morayshire) which give a clear profit of £20,000 a year. Again, a German medico who recently returned from Peru, after nearly ruining himself as a cinchona planter, has made a fortune in "cotton," growing the very finest kinds and getting several crops in the year in that most wonderfully dry and productive climate. The "Alfalfa," the pasturage so much praised by Mr. Clark (and of which I believe he sent seed to Kew) is simply "the Lucerne" grown in England since the time of our grandmothers, though it no doubt prospers exceedingly in Peru. On page 8, Mr. Clark confounds the position of two towns; for Tarma is smaller than "Jauja" and is served by the latter. Under the "Tropical Zone," I doubt if Mr. Clark does not advance his personal experience ("of other tropical countries I have visited") and opinion, after a more liberal fashion than probably Dr. Trimen, Mr. Neek and the two modest Planting Commissioners would have ventured to do. I refer to page 10, and among the rest the opinion expressed regarding the "soil" is likely to be contradicted. On page 11, some figures are given regarding "coffee" which are scarcely encouraging as I work them out; for in the valley of "Chanchnayo" we are told that coffee bears up to 8 and 10 cwt. per acre, and yet the total outturn of 100 gardens of from 8 to 30 acres each, is only 2,500 cwt. or the equivalent of a miserable 1½ to 3 cwt per acre.

On page 17, information is given respecting the size of cacao pods, but I am told that the Commissioners never saw any mature pods.

I might pursue the criticism, but what has been said will perhaps serve to qualify to some extent, the statements made in this very long, "able and interesting" report of Mr. Clark as Assistant to the Commissioners, which you will no doubt reprint in full for the *Observer* and *Tropical Agriculturist*. The more modest, though perhaps more practical and reliable report of the actual Commissioners themselves, will probably appear

* By Mr. J. Ferguson.

before next mail-day comes round; and if I am favoured with an early copy I will take care you have the benefit.

Meantime, undoubtedly Mr. Clark deserves credit for his great effort, and I am only sorry that for his own sake, and that of the Peruvian Corporation, who can only want to set forth everything correctly, he should have gone into print with an incorrect designation, and without due notice of his superiors, the Commissioners, and due acknowledgment of all he owed to, and learned from them.

A TEXT-BOOK OF AGRICULTURE.—The Royal Agricultural Society announce that the text-book on the "Elements of Agriculture" which has been prepared by Dr. W. Fream, in conjunction with a sub-committee of its council, will be issued on the 1st of January. This work, which will consist of 450 pages, with 200 illustrations, should prove one of the most valuable works on agriculture that we have. It is not intended to be—as most text-books are—something to cram from for examinations, but a clear and definite exposition of the principles which underlie the art of agriculture in its relation to the soil, the plant, and the animal, and the various sections have been carefully revised by such sound and eminent authorities as Sir John Lawes, Sir John Thorold, Sir Jacob Wilson, Mr. Alfred Ashworth, Mr. Thomas Bell, Mr. Bowen-Jones, Mr. Chaudos-Pole-Gell, Miss E. A. Ormerod, Mr. D. Pidgeon, Mr. Martin J. Sutton, Mr. Charles Whitehead, Dr. Voelcker, and others. —*Chemical Trade Journal.*

CULTIVATION AND AGRICULTURAL STATISTICS FOR MADRAS PRESIDENCY.—The net area cropped in the several districts of the Madras Presidency during the official year 1890-91 was 23,702,280 acres, but the acreage under crops was 26,095,518 acres, which is due to 2,393,238 acres having been cropped more than once. Of the grains, &c., cultivated, rice comes first with an acreage of 6,159,628 acres; cholam or jowar (millet) 4,429,081 acres; cumbu 2,716,812 acres; ragi 1,639,109 acres; grain 137,650 acres; maize 42,040 acres; wheat 18,258 acres; barley 3,534 acres; and other food grains 5,358,810 acres. The lands cultivated with oil-seeds were 1,918,705 acres in extent; of this 751,986 acres were under gingelly, and 26,065 acres under linseed. Condiments and spices took up 375,629 acres; sugarcane 56,870 acres, and other sugar produces 33,942 acres. The extent under cotton was 1,737,722 acres, and under other textile fibres 91,370 acres. Indigo was cultivated on 255,511 acres, and other dyes on 3,349 acres. Opium is but sparsely cultivated in this Presidency, and occupied only 181 acres, of which 177 was in the Kistna district, 2 in Anantapur and 2 in Coimbatore. Indian hemp took up 105 acres in Nellore, Kurnool, North Arcot and Salem. Coffee was cultivated on 70,219 acres; cinchona 13,407 acres; tea 89,989 acres; and tobacco 89,989 acres, and other drugs and narcotics on 12,381 acres. Padder crops occupied 24,895 acres, and miscellaneous food crops 18,631 acres. According to statistics prepared by the Agricultural Department the total number of bulls and bullocks in the Presidency during 1890-91 was 4,226,332; cows 3,888,481; male buffaloes 900,036; cow buffaloes 1,497,530; calves and buffalo calves 4,458,434; sheep and goats 12,560,076; horses and ponies 46,106; mules and donkeys 127,302; camels 42; ploughs 2,536,167 and carts 413,549. —*Madras Times.*

THE GOVERNMENT AND AGRICULTURE.—The *Singapore Free Press* of March 1st, writes:—

It is to be supposed that the Government are in earnest in issuing, to district officers and the British Residents in the Native States, their recent circular relating to the encouragement of padi cultivation. In connection with the Forests Department, and also with the local agricultural shows at Malacca, Jasin, &c., the introduction of some systematic encouragement of agriculture by Government has been strongly

advocated by us, and we also suggested that local committees and district officers should be made the agencies for carrying the schemes recommended by a central board in Singapore. Something should be done, and Mr. Ridley has only to be invited to outline a scheme for the idea, so long mooted, to take practical shape. The district shows, in addition to their social uses in bringing the people of the district together and also affording much useful instruction by the opportunity given of examining and comparing products, display the Government in a pleasant paternal way, as the giver of rewards rather than as a collector of revenue. That relation between Government and the people cannot be too frequently exhibited, and with this view we would suggest that to fit Civil Service cadets as the district officers of the future they should be retained longer in Singapore and be required to go through a course of instruction in economic products and agriculture under Mr. Ridley's direction. Ceylon is far ahead of the Straits in the fostering of agriculture, and we now extract a few passages from the report of the prize distribution, presided over by the Governor, at the Ceylon School of Agriculture. Extracts are then given from the speeches of Mr. Driberg, Mr. Cull, and Sir Arthur Havelock; and our contemporary continues:—

With all the natural advantages possessed by the countries of the Malay Peninsula for the cultivation of many valuable products it is surely the business of Government to take upon itself the duty of fostering and encouraging agriculture in a systematic manner. In turning the minds of the people to the cultivation of many useful products with which at present they may not be acquainted, or to the improvement of their present agricultural methods, it should not be lost sight of that by thus importing fresh matters of interest into their life, not only are the cultivators benefited materially, but influences are brought to bear of a distinctly educative and civilising value. And this indirect aspect of the Government fostering of agriculture and planting among the native populations is by no means to be under-rated.

TROPICAL AGRICULTURE IN COSTA RICA is noticed in the following letter to our address:—

San José de Costa Rica, C. A., Jan. 23, 1892.

I have recently become very much interested in tropical agriculture by residence here and connection with the banana business.

We ship over a million bunches yearly of what is known commercially as the 'patriota banana,' a third of which comes from our own estates. Our 'suckers' were obtained eight or nine years ago from Colon.

Nothing has been done yet by way of cultivation except clearing the bush twice a year and planting the trees 15 to 20 feet apart. We are paying grower 40c paper, say 25c gold, for bunches having over ten hands at which they make a fair profit as estates on good land are supposed to pay for themselves in five years.

Having the general management of the estates of my uncle, M. C. Keith, Esq., am anxious to try the improvement of the fruit by inter-crossing and such cultivation as the scarcity of labor and the value of the product will permit. Am therefore collecting all the data possible relating to the banana plant, but as yet have failed to collect anything of practical value. No botanical work that I possess contains much more than the mere mention of the plant.

Should you know of any literature on the subject or could direct me to anyone that could give me information I would be extremely grateful.*

The coffee crop this year is much smaller than usual, and there is much uneasiness on the part of the growers and shippers over the expected 'drop.' Money is very tight and exchange is 'booming.' Many of the leading men are expecting a crisis soon. Fortunately we have been spared the 'leaf disease.' So far it exists only on old places that have been neglected and planted too close.†

* Our correspondent will, we think, find what he wants in Watt's Dictionary of Indian Plants.—*Ed. T. A*
† A coffee disease, but not the deadly *Hemileia vastatrix*.—*Ed. T. A.*

Correspondence.

To the Editor.

VEGETABLE PARASITES.

Colombo, Feb. 19th.

SIR,—As you surmised, I was greatly interested in your extract from the *S. I. Observer*, referring to the poisonous nature of nux vomica leaves and the non-poisonous qualities of the parasites growing on the tree. In my communications to your paper on parasitic plants, I pointed out that *Loranthus*, mistletoe, and such green plants were partial or false parasites. Now these do not imbibe the elaborated sap consisting of organic substances, but they glucosify, vegetable acids, or alkaloids such as brucine or strychnine, but only absorb the ascending sap consisting of substances in solution, which the host has derived from the soil. The difference between the partial parasite and an ordinary plant is, therefore, that while the ordinary plant is fixed in the soil the partial parasite is fixed on another tree; they both absorb substances in solution derived from the soil and not yet elaborated into organic compounds. The manufacture of the materials found in the crude sap into organic compounds is done by each green plant for itself, no matter what the source of those materials and whether they be derived directly from the soil, or only indirectly through the medium of another tree. Thus it is quite possible that while *Strychnos nux vomica* elaborates strychnine and brucine, just as some plants elaborate citric acid, or tartaric acid, or alkaloids such as papaverine, daturine &c., *Loranthus* and *Viscum* elaborate neither of the alkaloid found in their host. Plants are able not only to elaborate specific and characteristic compounds, but also to exert what appears to be a selective power with regard to the food they derive from the soil. No wonder that some people who are apt to draw too hasty inferences, attribute intelligence to the individuals of the vegetable world!—Yours &c.,

T.

POISONOUS VEGETABLE PARASITES.

DEAR SIR,—I read with interest an article in your issue of the 18th inst. It wakes past recollections, and as the matter is of importance, I am induced to write to you. The article I refer to is "*Nux Vomica leaves poisonous while parasites growing on the tree are not.*" I shall shortly prove that one of the parasites, at least, is poisonous.

I may premise that only the seeds of *Strychnos nux vomica* are used in medicine under the name of *Nux vomica* or *Poison nut*. The seeds are rarely used in the form of powder; the preparations more commonly used being the extract, Tincture and the Alkaloid *strychnia*. The poisonous properties of the seeds are due to three alkaloids closely related—*strychnia*, *brucina* and *igasuria*; but the most important of these is *strychnia* (now named *strychnina* or *strychnine* in the British Pharmacopœia). *Nux vomica* is a valuable remedy in proper doses; but given in too large quantities, it acts as a powerful poison, speedily causing tetanic convulsions and death.

In my student days in the medical college of Calcutta (1838-42), I was clinical clerk to Dr. O'Shaughnessy, the author of the "*Bengal Dispensatory and Pharmacopœia.*" I have an infinitesimal share of credit in the production of the book, having helped to index the contents.

Dr. William Brooke O'Shaughnessy (afterwards Sir Wm. O'Shaughnessy Brooke) died at Southsea

only three years ago (January 1889), in his eightieth year. He was a learned physician; but was better known as a chemist and an electrician. Dr. O'Shaughnessy came out to India as an Assistant Surgeon in the Bengal Medical Service in 1833. He was already known to be an able chemist from contributions to the *Lancet* and his other writings. On the establishment of the Medical College of Calcutta in 1836, he became Professor of Chemistry and *Materia Medica*. In 1852, he was appointed Superintendent-General of Telegraphs in India, a post which he resigned in 1862, when he retired from the Indian Medical Service. He was a fellow of the Royal Society, and was knighted on account of his valuable services in establishing a system of telegraphs throughout India and Ceylon.

When Professor of *Materia Medica* in the Medical College and Physician to the College Hospital, Dr. O'Shaughnessy carried on investigations into the properties and uses of Indian drugs. The work I have mentioned was published chiefly as a class book for the students of the Medical College and was issued "by order of Government." I have still the old book with me, and also an old case-book containing reports of cases in which Indian drugs were prescribed by Dr. O'Shaughnessy, the effects of which we were to watch and note. One Indian remedy at least has, through his labours, found a permanent place in the British Pharmacopœia. Indian Hemp (*Cannabis Indica*) was one of the remedies we were frequently using. In Squire's Companion to the British Pharmacopœia, it is stated—"We are indebted to Dr. O'Shaughnessy for the first introduction of Indian Hemp into this country. He brought over a quantity from India, which the author ("quire) converted into extract for him, and distributed amongst a large number of the profession under Dr. O'Shaughnessy's directions."

Dr. Waring's "*Pharmacopœia of India,*" published in 1868 under the authority of the Government of India, may be considered to be an enlarged and improved edition of Dr. O'Shaughnessy's book; and was also intended to be a text book for students in India. I subjoin extracts from the "*Bengal Dispensatory.*" Dr. Waring states that the distinctions between the true and false *Angustura* barks were pointed out by Dr. O'Shaughnessy in 1837; that the bark of the *Nux Vomica* tree is poisonous and that Professor Christison (Sir Robert Christison) considered it might be advantageously substituted for the seed in the preparation of *Strychnine Casparia* or *Angustura bark* obtained from *Galipea Casparia* a South American tree, is in the British Pharmacopœia; but although the infusion of it is a good stimulant and tonic it is, so far as I know rarely or never prescribed. *Angustura bark* came into use in England in the latter part of the last century and was imported directly or indirectly from South America. The bark of the *Strychnos Nux Vomica* began to be imported and used as *Angustura Bark*, and owing to the serious consequences which ensued in the beginning of this century from the adulteration the true bark began to be but little employed. Dr. O'Shaughnessy traced the origin of the "*False Angustura*" of commerce. He also prevented serious consequences which might have arisen from another source. He ascertained that the *Nux Vomica* bark was being sold at Calcutta for an Indian remedy, the bark of the Rohun tree (*Soymda febrifuga*) astringent, tonic and febrifuge. A chemist obtained what he thought to be a new alkaloid, allied to quinine from Rohun bark; and it was being manufactured for use in

the Indian army as a substitute for quinine. Dr. O'Shaughnessy discovered that the bark which was being used, instead of the harmless Rohun bark, was the bark of the Nux Vomica tree, and that the alkaloid which was being extracted was *brucia*.

There can be little room for doubt that the leaves of the Nux Vomica tree are poisonous. The parasite (*Viscum monoicum*) growing on the tree is also poisonous. The analysis given in the extract from Dr. O'Shaughnessy's book shows the presence of both strychnine and brucine in the leaves of viscum. Dr. Waring in the "Pharmacopœia of India" (page 108) states that in a communication to him Sir W. O'Shaughnessy had mentioned a case of poisoning from viscum. The occurrence took place when I was a student in the college. Dr. O'Shaughnessy was trying to bring viscum into use as safer than Nux Vomica. A robust European sailor under treatment in the surgical wards, had by mistake half a drachm of the powdered viscum leaves administered to him instead of rubets. The poor man died from violent convulsions in less than an hour. Dr. Anthonisz, who was my fellow student, will remember the occurrence, the excitement and the coroner's inquest in the occasion.—Your obedient servant,

JAMES LOOS, M. D.,
Retired Colonial Surgeon.

P. S.—Since writing the above, I have read in your issue of the 20th inst. the letter of your correspondent "T." He writes ably, and I have no doubt is an expert. Parasites on the nux vomica tree may not be always poisonous, but from what I have stated it will, I think, be evident that "the parasitic guest in imbibing poisonous juice from its host has not always power to eliminate the poisonous principles."

(Extracts referred to.)

This family (*Loranthaceæ*) consists of parasites, which are not only sustained upon, but take root in the substance of other trees. The chief genera are viscum and loranthus, the former well-known as the mistletoe of the druids.

No medicinal properties of any importance had been observed in these plants until we accidentally discovered, in 1836, that the viscum found on the nuxvomica trees of Cuttack possessed all the properties of the supporting tree. As we believe the occurrence has attracted some attention, and is of considerable interest in botanical physiology, we deem it necessary to state the particulars in detail.

In 1837, Lieut. Kittoe, then with his regiment at Cuttack, received information of the existence of a parasite on the nuxvomica trees, to which extraordinary medicinal powers were attributed by the natives. They call it *kuchila ke mulung*, held it to be an extremely powerful narcotic, and poisonous in small doses, and they used it in the treatment of agues and rheumatism. Mr. Kittoe having procured specimens of the leaves sent them to the editor for experiment.

Given in three grain doses to dogs and kids tetanic spasms set in, in the course of from five minutes to a quarter of an hour, recurring at intervals, and proving fatal by fixing the diaphragm, and causing asphyxia. The convulsive movements were precisely the same as those occasioned by strychnine, brucine, and the nuxvomica seeds or bark. On analysis the powdered leaves yielded—

Green colouring matter and fibre	64
Wax	.. 4
Strychnine	.. 1
Brucine	.. 3
Extract	.. 18
Saline matter and Resin	.. 10

100

Specimens of the leaves were referred to Dr. Wallich, who supposes them to belong to the *viscum monoicum*; but no fruit or flowers having been obtained this point is not yet clearly ascertained.

Mr. Kittoe subsequently favoured us with a branch of the nuxvomica tree in which the parasite was firmly rooted, but as neither fruit nor flowers were present the difficulty in identifying the species was not removed.

The powder of the dry leaf has been used with complete success as a substitute for strychnine and brucine in the hospital of the Medical College, by Dr. Duncan Stewart, and by several other practitioners. The dose is one to three grains thrice daily. The precautions observed in using strychnine and nuxvomica are equally necessary with this remedy; it should be remitted as soon as tingling or spasmodic contractions are observed.

The *viscum album*, or white mistletoe, is generally supposed to be the parasite which held such an important part in the superstitious ceremonies of the Druids. It yields no medicinal product, but the berries are used for the manufacture of a kind of glue, of little importance even in the arts.—*The Bengal Dispensatory* pp. 375, 376.

This bark (bark of *strychnos nuxvomica*) is known to the European druggists under the name of the *false angustura*. Its nature was long suspected, but first clearly ascertained by the editor of this work, (see the *Journal of the Medical and Physical Society of Calcutta*, Jan, 1837.) The same bark is commonly sold in Calcutta, under the name of "Rohun," and substituted for the harmless bark of the *soymida febrifuga*.—*The Bengal Dispensatory* p. 437.

TEA IN TASMANIA.

Derby, Tasmania, Feb. 25th.

DEAR SIR,—Some time ago I took the liberty of pointing out to the Tea Planters' Association of Ceylon the wisdom of establishing a direct tea trade with the Australian colonies, but received in reply a memo. from their Secretary at Kandy, stating that my proposal had been submitted to the Directorate, but they regretted their inability to entertain my proposals. Although in proposing a direct establishment of trade with the Australian colonies I, to a great extent, was an interested party, in that I offered myself as a candidate for the appointment as representative. Still I think that my proposal should have met with more consideration than the amount bestowed upon it, for these reasons:—

First, that the colonials are great tea drinkers. The amount of tea consumed in the colonies is simply astounding, rendered still more so by the fact that the tea used is of the poorest quality. During the month of December last the amount of tea imported into this colony alone reached a total of 46,661 lb; valued at £2,396 cost; the retail price would be at least 15 per cent more. The amount received and bonded in addition to the amount remaining in bond from December 1891 was 43,173 lb. for Launceston alone; that for Hobart was 100,135 lb. This is independent of the lesser ports, of which there are some ½ dozen. These facts speak for themselves. The total amount of tea imported into the colony of Tasmania for the months of December 1891 and January 1892 reached a total of 64,833 lb., and if this enormous consumption of tea does not offer sufficient inducement for the establishing of a direct trade with the colonies by an Association, whose very name and standing is a sufficient guarantee for the quality of their tea, I am at a loss to know what will.

I can positively state that the sale of tea such as produced in Ceylon would be both considerable and easy. Quantities of tea, bearing the brand "Ceylon Tea" are being continually offered in colonial markets; and so anxious are consumers for tea of good quality that the name of Ceylon tea at once guarantees its sale. Colonial teas, as a rule, are those of the most inferior kind. I trust that you will find space in your valuable publication for the insertion of this letter, as by so doing

benefit may accrue to colonial tea drinkers in the introduction of a better article than that at present purchasable here.—Yours truly,

R. W. GUSBOULT

[Ceylon tea is rapidly making its way in the Australian colonies in the ordinary course of commerce, merchants shipping to their agents in the various ports. No necessity was, therefore, seen for a special agent.—*Ed. T. A.*]

MOISTURE IN PREPARED TEA.

Great Western, Talawakale.

DEAR SIR,—Could you kindly inform me how much moisture per cent there is in an average dried sample of tea as usually shipped from Ceylon.—Yours truly,

OLIVE MEARES.

[The average percentage is about 3.50.—*Ed. T. A.*]

THE NEW PAPER LINING FOR TEA CHESTS.

Queen's Hotel, Kandy, March 12th.

DEAR SIR,—From what I have heard from time to time since my arrival in this island it would appear that it is not generally known what the saving in cost amounts to in using these linings as compared with the lead. For the purposes of general information perhaps you will allow me to state through your columns again the exact price at what these linings can be obtained from Messrs. Darley, Butler & Co., Colombo, viz. for chests to contain 100 lb. nett 54 cents, half-chests to contain 50 lb. nett 46 cents. A comparison of these prices with the cost of lining the same packages with the ordinary lead linings will speak for itself.

The sales of this paper are steadily increasing.—Yours faithfully,

J. M. MITLAND-KIRWAN.

INFORMATION WANTED ABOUT PERAK.

Dolosbage West, March 19th.

DEAR SIR,—Perhaps you will be good enough to give a constant reader a little information about Perak—best route thither, where land is to be had suitable for coffee and cacao, titles, price &c., and anything else you consider worth mention.—Yours &c.,

PLAYED OUT COFFEE ESTATE.

[In our issue of the 4th inst. we reprinted from the Perak Handbook some information which our correspondent will find of use.—*Ed. T. A.*]

VEGETABLE PARASITES.

DEAR SIR,—Quite recently, the Government of the Straits Settlements enacted a law in the interests of the owners of coconut trees, forbidding, under penalty, the accumulation of rubbish in heaps, in the vicinity of coconut trees, rubbish heaps being the breeding places of the beetles, which play "Old Harry" with the coconut trees in the Straits. I mention this good move on the part of the paternal Government at Singapore, with the object of calling the attention of at least our eminent Municipality to the increasing spread of the growth of the parasite on our trees a parasite, which, I believe, is known to the botanist as the "Loranthus"; by the natives as "Pelo."

Wherever you may go, about Colombo, you will notice luxuriant growths of this destructive parasite, especially on mango trees; many of these look as if they were being gradually starved to death, by the parasites [drawing away the sap for their own nourishment.

Is it not time, in the interest of the general community, to require that owners of trees should keep their tree free from parasites. If they will not do so themselves, do it for them, and recover the cost.

Some so-called friends of the "down-trodden and oppressed natives" who are anxious to obtain more leisure for these hard, working folks to sit on their hunkers and scratch themselves, may say, "Why should not the poor goiyas have parasites on their trees, if they choose to? So they may; but at the same time no man has a right to keep up; to the injury of his neighbours, a centre, from which the birds will carry the seeds to the trees all around the neighbourhood. Some years back the planters complained, and very rightly too, that the seeds of weeds from neglected adjoining estates were blown on to their own estates to the increase of the cost in weeding. If I mistake not, a nuisance of this kind would in England lead to an action for damages.

Requiring landowners to keep their trees, free from parasites, would be only one of the duties attendant on the possession of land, and would give employment to idle hands (especially those now more frequently engaged in stabbing and murdering one and other) when not engaged in scratching their hides, or in gambling or drinking.

During his last visit to Nuwara Eliya, I think, our late good Governor, Sir W. Gregory, called attention to the damage done to some ornamental trees at that station, by the unchecked growth of parasites. Where there is a will, a way will soon be found, to save trees, both fruit and ornamental, from further disfigurement and destruction.—Yours faithfully,

PROGRESS.

The gold industry in Demerara is rapidly developing, and the last shipment sent home from Georgetown was the largest on record. The total export for the year 1891 amounted to 101,297 oz., valued at over \$1,800,000. The total of the gold shipped from Georgetown in 1890 was 62,615 oz., so that the output increased in the twelve months by about 40,000 oz. This looks well, and, as the climate in the golden regions does not appear to be anything like so dangerous as was at first made out, there is no reason why the mining population on the fields should not increase rapidly.—*Colonies and India*, Feb. 27th.

TEA IN FOCHOW.—The *Fochow Echo* of 27th Feb. says:—The utmost the China merchant has done to preserve his trade has been to try to get the Export duty on tea reduced. That was a comparatively long time ago now, and the endeavour has since been calmly abandoned. As far as it went, it was a step in the right direction; but what was equally, if not more important, was the absolute necessity of adopting our rivals' tactics in the consuming markets, and this has been neglected altogether. We ought, and should have, if we had been alive to our own interests, to have forestalled them. We have been far too conservative. The days of the old merchant-prince are past, when the tea trade of the world was a monopoly of China. We can no longer say, take our teas or leave them. We must move with the times or we shall assuredly be left in the cold. According to the views of the *London and China Express* we have now seen the worst, and if it should be so we have to thank the medical profession. The mere thought of an arrest of the dowfall, after the prolonged rapid decline, is of itself satisfactory, but the consumption cannot remain permanently where it is—it must, in the long run, either be better or worse—and our merchants must determine which it is to be. It seems to us that some concerted action on the lines of that of our rivals, promptly set going at this opportune moment, would be the means of resuscitating the trade in a wonderfully, short space of time.—*N.-C. Herald*, March 4th.

IRISH POTATO RAISING.

(Extract from Forthcoming Bulletin of Virginia Experiment Station.)

METHODS OF CULTURE.

Much has been written upon the subject of methods of cutting, planting and cultivating potatoes, and the Experiment Stations have given considerable attention to work calculated to throw light upon these questions. Such work has an important practical bearing, but the results already obtained appear to cover the main points of the subject; hence but little attention has been devoted to it here. As a matter of general importance, we undertake to briefly discuss the main points of the subject, or, rather, to give the practical conclusions which seem to be warranted from the tests that have been made.

The questions which enter into this subject are—
1st. What size of tuber should be used for seed?
2nd. Should the seed be cut or planted whole?
3rd. If cut, to what size of pieces?
4th. Should the seed be planted in trenches or upon the surface?
5th. How should fertilizers be applied?

There are several points of view from which each subdivision or question, noted above, may be discussed.

(1) THE SIZE OF SEED.

This question, in one of its aspects, hinges upon the other question of whether there is a decided tendency on the part of varieties to deteriorate or not, and whether careful selection of seed, in any degree, mitigates this tendency. There can scarcely be any longer a doubt in the mind of cultivators who have given the subject attention, that varieties do deteriorate. Also, it is well known that deterioration is less marked where careful selection and good culture are given, and climatic influences are propitious. In support of this the common fact may be cited, that after an old, choice variety has practically disappeared from general cultivation, or at least good stock of it can, with difficulty, be secured, a choice lot of seed may often be obtained from some locality where it has been kept pure and maintained fair vigor through the fact of its being well-adapted to the soil and climate of that region.

The main fact of variety deterioration is clearly established and needs no argument. This doubtless has its main cause in the fact that potatoes are solely propagated by bud division, and not by true botanical seed—i. e., that in which there has been the union of sexes, as in the grain of wheat, kernel of corn, &c.

This being true, the importance of selection of individuals from which to propagate is at once apparent. But the question of the potency of the individual tuber does not rest alone upon its appearance and size, but in part upon the vigor, health, and prolificacy of the parent plant. Hence it is at once plain that there can be given no fast rule by which to select potato tubers from appearance.

It is quite generally believed among students of this question that something might be done toward keeping up the quality and vigor of variety by careful selection from vigorous prolific plants, but not enough has been done along this line to warrant any conclusion. Our belief is that in the selection of potato-seed nothing more can be done than to choose those which conform as nearly to the type of variety as possible, and are perfectly sound and well-matured.

It would not be advisable to select all of the very large tubers for seed, as such seed cuts more to waste than smaller tubers; nor would it be desirable to select very small tubers, as they certainly furnish less substance to the buds when starting. Any sound, well-shaped tuber of the size of a hen's egg and upward is perfectly proper seed.

(2) PLANTING CUT OR WHOLE SEED.

This question hinges somewhat on the previous one, and also upon economy of seed, method of planting, and object had in view in growing the crop.

As a general statement, we would say that if potatoes the size of a hen's egg and upwards are selected, and it is desired to economize seed, they should always be cut. If smaller seed be used, they may as well be planted whole; but if planted in a carefully prepared soil, will do fairly well cut in halves. If early maturity is desired, medium-sized whole potatoes, or larger ones cut in halves crosswise, are advised. A small area planted in this manner will usually come to edible maturity several days sooner than if cut to "two-eyes," as stated under following head.

This question bears so upon the following one that we discuss it more fully below.

(3) WHAT SIZE SHOULD SEED BE CUT?

No question in the culture of potatoes has been wrangled over in newspaper and other discussion to the extent that this one has. Fortunately, experiments on this point have been sufficient to teach, with reasonable certainty, the following facts:

1st. That, almost without exception, good healthy, average size tubers will give better results in crop and economize seed if cut to "two-eye" pieces, as is further described below.

2nd. That with varieties producing small growth of vines, and when close planting is practical, with soil in excellent condition, seed may be safely cut to "one-eye." We do not recommend this practice.

3rd. That larger cutting than two eyes (except the eyes are very close on the tuber) is waste of seed, unless it is desired to force the plants along rapidly. This the larger cutting will usually do.

4th. That when larger cutting is practiced, it is just as well, and perhaps better, to cut the tuber crosswise than lengthwise.

The stem-end, middle, and seed end eyes, show about equal vitality under equal conditions.

GENERAL OBSERVATIONS ON CUTTING SEED POTATOES.

A very large amount of data and discussion has been printed on the subject of methods of cutting seed potatoes, and the conclusion has appeared in print that the yield of crop is found to be proportional to the quantity of seed planted. This conclusion needs to be carefully qualified, which has not always been the case in publications where it has appeared. It is perfectly true that whole medium or large-sized potatoes usually give and increased yield over smaller tubers or small cuttings, and also show a gain of a few days in edible maturity. But they also show a very decidedly larger yield of small or unmerchantable tubers, and increase the cost of seed many fold, varying of course with size of tuber used.

This may be illustrated by stating that seed cut to "two eye" pieces requires 8 to 10 bushels to plant an acre, if the pieces are placed 10 to 12 inches apart in the row, and the rows 2½ to 3 feet apart. Whole seed planted in hills 12 to 20 inches apart will require 40 to 60 bushels to plant an acre.

The conditions desired in growing potatoes is to place the plants so as to occupy the entire ground, having them just far enough apart to secure good individual development of tubers. This can be best accomplished by small cuttings planted closely, say rows 2½ feet apart and planted 10 inches apart in rows. With Early Ohio, Early Hebron, Sunrise, and several other varieties so planted, nearly the entire yield will be of marketable size.

There is much room for skillful work in cutting seed potatoes. The often-practiced method of cutting the tubers in two lengthwise or crosswise at random, and then cutting these pieces into smaller portions, is reprehensible. There is, in our estimation, but one proper method of cutting seed; and we believe that growers who have once tried this method will assent to the above statement.

To illustrate this, we here reproduce a cut which has been commonly used to advertise a certain knife made especially for this purpose. The method of cutting which we allude to is to take the tuber in the left hand, holding the stem end downwards and towards the operator. Turn it so as to bring the lowest eyes towards you, then with a sharp thin knife cut them out, making a curving down-

ward stroke extending to the centre and base of the tuber. Turn tuber slightly to bring other eyes toward the operator, and repeat the operation. The eyes of a potato are arranged more or less regularly around a spirally-ascending axis and by turning the potato slightly after each operation they can be cut away in compact pieces so as to give each one a nearly equal proportion of the tuber. This, of course, cannot be done at the seed end, and when the operator has removed the eyes as close as practicable to the seed-end, a good practice is to cut it down through the centre.

This method of rotating the tuber and cutting the eyes away successively is fairly well shown in the cut Fig. 1. There, however, the illustration shows the pieces cut to one eye. This, as stated elsewhere, we do not advise except under certain conditions, but the system of cutting works equally well with the two-eye cuttings, and for ordinary seed we advise about that size. The importance of properly cut seed is little appreciated among many growers, hence we feel justified in giving considerable space to this matter.

Armed with a good knife, a smart hand should cut 8 to 10 bushels of seed per day. We do not advise cutting seed in advance of planting, but if it is done to save time in the rush of work, the pieces should be thoroughly dusted with plaster to prevent evaporation.

(4) PLANTING IN TRENCHES OR UPON THE SURFACE.

This is another point in potato culture that has been much discussed, but the best growers now quite uniformly follow the trench system. However, to many there may be some new points about the process—hence we give it some discussion, with an illustration. The trench system is alluded to under the discussion of planting the varieties. We have used this system for about ten years, and consider it much superior to surface-planting.

Our reasons are,—

1st. That it is the easiest method of planting, as it permits the covering to be rapidly and easily performed by horse-power.

2nd. It places the plants down in the soil, where they are more secure from effect of drought.

3rd. It obviates the necessity of hilling up, and enables one to give the crop level culture, which experience has shown to be the best; and,

4th. As a result of the foregoing conditions, the crop will usually be larger and of better quality for being so planted.

It is our experience that deep culture of the crop, hilling up, hand-hoeing, etc., if given after the vines begin to lop over, injures the crop, especially in that these practices tend to produce small tubers.

The illustration here given, figures 2, shows the implement we use in furrowing and planting. The furrowing attachment is a part of a combined tool used for cultivating and various other garden operations. The furrower is a wide, two-winged shovel attached to rear central standard, and the marker gauge is a graduated wooden bar attached to the forward part of the cultivator frame. On this bar there is a transverse flat bar of iron so fastened that it can easily and quickly be adjusted to the desired width of the row. The gauge-bar has also attached to it a lever-rod within reach of the operator, with which he can rotate it from side to side.

With this instrument furrows can be accurately gauged and rapidly laid off any desired width from 2 to 4 feet. The ground should be well-prepared, or the work of opening the furrows and covering by horse cannot be satisfactorily performed.

Our custom is to lay off the furrows 2½ feet apart and 5 inches deep. This leaves the ground in a continuous succession of ridges and depressions, the latter representing the rows.

After the seed is dropped the same tool, with gauge-bar removed, is used to do the covering. This is done by driving the horse up on the ridge of earth between the furrows of each row, and holding the plow deep enough to turn back rather more earth than was turned out of the furrow. The result is that after covering, in this manner, the ground

still represents a continuous serration of ridges and slight depressions. Left in this manner, the soil warms up more quickly than if flat; and another point is that the ridges can easily be broken down later by a harrow, thus giving the ground a thorough cultivation. This latter operation should be performed just when the plants begin to break through the soil.

Drive the harrow across the ridges, and do the work thoroughly; no harm will result to the plant. A common spike-tooth harrow is best suited for this work.

(5) APPLICATION OF FERTILIZERS.

This question is ever new. It recurs on every change of soil, and systems of rotation and cultivation have a bearing upon it.

Of the cultural problems it is the only one receiving any considerable attention at this Station, and it is hoped to carry on tests concerning this question at various points in the State.

When and how fertilizers should be applied depends upon what is to be used. If barn-yard manure, it should be well rotted and applied in the fall or early winter, and worked thoroughly into the soil before planting. Barn-yard manure should not be applied so as to come directly in contact with the tubers. It should not be applied in such condition that it will undergo active fermentation in the soil. In case of its coming in contact with the tubers or causing active fermentation, it is thought to predispose the tubers to the disease known as "scab."

The manure is not the direct cause of the disease, as has been sometimes supposed; but under the conditions mentioned, it may act upon the skin in such a manner as to render the tuber more liable to attack.

If chemical fertilizers are used, it is best to make the application of them after the ground is fully fitted for planting. There has been much discussion as to whether concentrated manures should be placed above or below the seed. On this point no definite conclusion has been reached, but it is our opinion from tests of this character that if the fertilizer be sown across the furrows before dropping the seed, about the best results will be reached. This places a portion of the fertilizer in the furrow, and the remainder, being scattered over the adjacent soil, is fairly well incorporated with it, and turned mostly upon the row in the act of covering with the furrowing mentioned under previous head. Potato roots are thought to feed within a moderate area; yet we do not believe it is best to apply the fertilizer in too close proximity to the seed.

FERTILIZER TRIALS CONDUCTED HERE.

Considering that this question is of real importance in the cultural problem, we have been endeavoring to so conduct a series of test plots as to throw light on the matter. The results thus far are practically valueless, but a brief discussion is given.

The test is planned on the basis of the chemical analysis of the potatoe, which shows that a crop of 300 bushels of tubers contains,—

* About 54.0 lb. of nitrogen (N).

104.4 lb. of potash (K 20).

28.8 lb. of phosphoric acid (P 2.05).

Working from this data, a complete fertilizer would contain of the high grade chemicals used in mixing fertilizers as follows:

Nitrate of soda (Na N 03, 98 per cent.), 334.5 lb.

Muriate of potash (KCl 85 per cent.), 180.2 lb.

Dissolved bone black (P₂ O₅ 19 per cent.), 151.6 lb.

The above formula gives, according to our data, a complete manure for a crop of 300 bushels of potatoes. But the question of what results may be expected from its use upon the soil can only be answered by experimentation. Theoretical conditions can only be obtained in the laboratory, and all plot experimentation must contend with so many conditions, the value and potency which cannot be known, that results

* Landorp's Kal., 1890.

of one or two years' work are of little avail in solving a problem. The plots used for the application of this fertilizer contained 600 square feet of area, and were thought to be fairly even in fertility; but the results showed so little value that no proper interpretation could be given them if they were published. The test last year was also equally unsatisfactory, and was not published.

The plan of the test comprised a series of three plots treated with each of the chemicals, separately used, in full ration, half ration, and double ration; and an unfertilized plot was left after each series. Then followed combinations of all three of the chemicals in the same proportions, always leaving each fourth plot unfertilized. Thus was arranged a series of twenty-four plots, making all possible combinations which could be made with the ingredients named, in full, half, and double ration quantities. This, it appears, ought to have given a sufficient series of tests to show somewhat the needs of this soil, but on the contrary the results teach absolutely nothing. There is difference of yield in the different plots, but they bear little relation to the treatment.

The soil of these plots was carefully prepared in the same manner as for the variety test, and planting was the same and done at the same date. The variety used was sunrise, and the crop was of excellent quality.

We are not at all satisfied with such results, and the work will be continued but it is much to be hoped that tests of this character can be carried to a region of the State where sandy soils of fairly even quality can be tested with a similar series of fertilizer work.

—W. B. ALWOOD.—*Southern Planter*.

[The above was referred to Mr. Nock, who remarks: "The methods of cultivation with the implements mentioned could not be put in practice in Ceylon owing to the steepness of the land where the profitable cultivation of Potatoes is likely to succeed. With regard to size of tubers for sets, cutting of tubers, &c., I don't think I need say any more than what was printed in Dr. Trimen's last report, page 19." —ED. T. A.]

CULTIVATION OF MAIZE.

Although the learned author is somewhat out in some of his statements, when viewed from a Queensland standpoint, the following article which is from the pen of Prof. Shelton and has been issued by the Agricultural Department, is so excellent that we reproduce it in extenso:—

Indian Corn is in its organisation the most flexible of plants. Certainly no other farm plant is presented to us under such an infinite variety of forms. In the far north it scarcely attains to a height of 3 feet, and makes this growth in less than three months' time, while in semi-tropical regions it rivals the palms in its tremendous development of stalk and blade. In its northern growth the grain of maize is presented in the form of tiny ears of small, rounded, flinty grains, while in the southern-grown product the kernels are greatly lengthened, flattened, indented discs, which on account of the large amount of starch possessed by them are comparatively soft and easily pulverised. Again, as is usual, each ear is closely enveloped by a tough husk, or this may be, as in self-husking sorts, more or less wanting, or each individual kernel may have its separate husk envelope, as is said to have been the case with the original wild maize. The writer has within a few years experimented with nearly or quite 200 distinct varieties, or rather sub-varieties of maize. The practical inference from all this is that there exists for nearly every condition of soil and climate a variety of maize suited to it.

MAIZE IN QUEENSLAND.

In the southern portion of the colony maize-growing has long been a favourite speciality with farmers. The aggregate annual production of corn must be very great, although I am unable to quote authoritative figures. But he that as it may, Queensland does not nearly grow the corn that is consumed within her borders. During 1889 the colony im-

ported, mostly from New South Wales, an aggregate of 216,254 bushels, valued at £35,414. This, with maizena, cornflour, and maize meal, brings the total value of our imports of maize and its products for the year up to £39,541, a very handsome sum certainly. From the fact that much of this imported grain paid heavy railway and ocean freight charges, and finally an import duty of 8d. per bushel, it is clear that Queensland prices of maize must be very high as compared with ruling prices elsewhere. Thus, during the past year, corn was selling for 7d. a bushel at railway points in the great corn-growing States of America.

It is clear that credit is not due to New South Wales for the large amount of corn which according to the Customs returns, came from that colony. New South Wales imported in the year in question 237,660 bushels of corn, of which 25,000 bushels came from the United States of America, and we have outside means of knowing that a good deal of this foreign grain ultimately reaches Queensland; it fetched in Brisbane 3s. 10d. to 4s. 2d. per bushel. At the present time, while corn is selling in the face of a very short crop, due to a protracted drought, at 2s. 3d. per bushel, at the same places in America, it is quoted in the Brisbane papers at 4s. 1d., and Queensland farmers tell me that a corn crop is not profitably produced in the colony when the price rules below 2s. 6d., equal to about 60 cents, per bushel at the farm on which it is grown. From these facts it would appear that either Queensland soil and climate are less well suited to the growth of Indian corn than America and the other States from which our supplies are drawn, or our farming methods are wasteful, directly in the use of labour, and indirectly by reason of our failures to employ modern methods and appliances. The United States is, of course, the great corn-producing nation. The corn-product of America in 1887 amounted to the enormous total of 1,455,161,000 bushels, exceeding in quantity and value all other grain and potato crops produced during the year. What Mr Webster said of the English turnip crop may be said with emphasis of the American crop of Indian corn—"Its failure for three successive years would bankrupt the nation." The yield of corn per acre in the United States, taken as a whole, was, according to the report of the Department for Agriculture for 1887, 20'1 bushels. The average yield per acre of the five great corn-growing States—Illinois, Iowa, Kansas, Nebraska, and Missouri—according to the same authority, was 21 bushels. The yield of maize per acre in Queensland during the same year was 22'31 bushels per acre. Inasmuch as farm labour is certainly no more costly in Queensland than in the United States, it would seem that either corn at present prices is produced at a very great profit to the farmer, or else his methods of production are unnecessarily expensive. My own opinion is that the present cost of making a corn crop may be materially reduced, and quite likely the yield increased and the crop made more certain, especially in dry years. The present bulletin has no more practical aim than to present to Queensland farmers some of the American methods in connection with the corn crop, in the hope that Queensland farmers may be able to gather some useful hints therefrom.

THE AGRICULTURAL COLLEGE AND EXPERIMENT FARM.

Until the Colony provides a properly-equipped experiment farm and means for teaching modern improvements we shall be forced thus to deal in facts at secondhand. We ought to be able to test the methods of other lands under Queensland conditions, and thus do for the agriculturalist what all experience shows he cannot or will not do for himself. Not alone in methods pertaining to the growth of maize does the Queensland farmer fail to get the benefit of modern improvements in the practice and science of farming, but in general grain-growing, the cultivation of the improved grasses, in dairying, in fruit-growing and preserving, and indeed in every department of the agricultural effort. Prevailing high prices enable the Queensland farmer for the present to discount modern improvements; but when

production shall have overtaken consumption, as is sure to be the case in the near future, the need of "turning over a new leaf" will be felt as it is not now. We ought to have—we must have, the means by which our farmers may get the stimulus of modern thought, and their sons be able to turn their energies towards "the better things of farming," and he who will of our public men be the Queensland Morrill or Sinclair "will be illustrious in all succeeding days as long as the profit of the earth is for all and the king himself is served by the field."

DROUGHT RESISTANCE.

Indian corn everywhere makes its best growth in countries whose climate tends towards dryness rather than the opposite extreme of wet weather. The great corn-producing States of America are all, without exception, subject to protracted droughts, which often reduce the crop fully one-half. Thus the Kansas corn crop, which in 1889 was estimated at 375,000,000 bushels, was in 1887, a year of drought less than 77,000,000 bushels. Similar fluctuations in the great crop might be pointed out in the case of every one of the "hog and hominy" States. Indian corn, as might be expected, ranks high among the crops capable of withstanding, without injury, protracted drought. However, this natural ability of the plant may be greatly strengthened and increased by means within the reach of the farmer. The practices conducive to drought resistance in the corn crop are stated or suggested as follows:—

1. Corn, in ground of poor tilth, lumpy, or surface baked, is always quick to give signs of suffering from dry weather.

2. Thickly planted corn fails with slight proevocation from dry weather. Of course the proper seeding will vary within wide limits, with different sorts. In my own experiments made in America the common slow-growing "dent" varieties did best when planted in rows 4 feet apart, with individual plants standing 16 inches apart in the row.

3. Judicious cultivation of the growing crop will greatly lessen the effects of dry weather upon it. Work the ground deeply and close to the growing plants while they are young; as the plants increase in size, work less closely to them and cultivate at shallow depths. Corn ought to be cultivated at least once in ten days until it is "laid by." In dry weather give the ground numerous shallow cultivations, thus making a mulch of the upper 2 inches of soil. Never allow the ground to crust over, and especially keep down the weeds which constantly pump from the soil the moisture which should go to the support of the corn plants. To prove the value of superficial cultivation in times of drought, cultivate lightly a portion of a field of suffering corn, and notice how soon the blades will mroll; but if the cultivator is worked deeply the effects of the drought will be felt yet more disastrously.

A CRITICISM.

Queensland methods in connection with maize culture, so far as I have been able to acquaint myself with them, seem to me to be open to serious objections—they are expensive in labour, and the crop is not properly utilised as it ought to be. Take the common method of planting corn as I have seen it done in level black soils;—the ground is first ploughed, then furrowed out with the same plough, after which the seed is sprinkled along the furrow by hand; then a furrow is turned upon the seed corn, and the planting is completed by harrowing the planted field smooth. This very complicated operation might be better done by using, after the land has been ploughed—(1) a corn marker, made of a heavy plank or log, with three "runners" or markers, which would mark out three rows with each movement across the field, and then by planting the grain with a drill, operated by a man and horse, which plants the seed uniformly at the required distances, and covers and presses the earth about it. Then, too, in Queensland, no use is made of the corn fodder, and practically the people have no acquaintance with maize as used in its various forms as an article of human diet. In America, well cured

corn fodder is considered equal, pound for pound, with good quality hay, while the grain, in the form of green corn, hominy, and corn meal, is an article of universal consumption.

MAIZE AS A HAY PLANT.

It may be questioned whether there is another plant in ordinary cultivation that equals corn as a fodder plant. For ensilage nothing has been discovered that will take its place. In America advantage is taken of this hay value of the corn plant to utilise the stalks after the grain has been removed. Ordinarily the corn is "cut up" at the time when the grain is "glazed" and in the "dough" state, while the stalks of the plant are yet green and succulent. The practice is to cut the corn at the height of nearly a foot from the ground and from a "shock" or "stook" from the growth obtained from 40 to 50 square feet of ground. The cut corn is stood up, butts down of course. The shock is tied securely at the top to prevent the admission of rain, and allowed to remain in the field until the fodder is thoroughly dried to the condition of hay. The corn is husked as suits the convenience of the farmer, and the fodder tied up in bundles convenient for handling, and these are stacked for use as needed. Another common practice is to top the growing corn by cutting the stalk just above the ear while the corn is yet green, but after the ears are fully formed. This fodder is tied in bundles and shocked in the field, where it is allowed to remain until fully cured. This form of corn fodder is a most perfect hay, which is eaten with great relish by horses and cattle. The portion of the stalk remaining with the ear has sufficient vitality to fully ripen the ear of corn remaining upon it.

CORN AS HUMAN FOOD.

Queensland farmers and people generally have practically concluded that maize is worthless as an article of human diet. The many people with whom I have spoken on the subject have generally expressed surprise that maize in the many forms in which it is used in America was available for table use. By some it is urged that corn which is rich in such "heat-givers" as starch and oil, and comparatively wanting in the proteid, is unsuited to the wants of the inhabitants of warm countries. Here as so often elsewhere, "a single fact is worth a thousand theories," and the fact that corn has been time out of mind the "bread-timber" of the negroes and work-people generally of the Southern States of America by whom it is eaten all the year round with salt pork or bacon—another most "heating" food—is in defiance of the theorists. The truth is, the whole subject of animal nutrition has been obfuscated by the speculations of those who have considered the subject wholly from a chemical standpoint. Practical considerations and the flexibility of the animal system often enable men to arrange their dietaries in seeming violation of chemical dicta. The inhabitants of the Arctic regions subsist largely upon fat, in the shape of butter and tallow, and those of inter-tropical regions upon like heat-givers, corn, pork and molasses, for the same reasons. These articles are abundant and easily obtained, and long use has led to the acquisition of a taste for them. It is difficult to think of a more delicious vegetable than the green corn so universally used in America. Preferably sweet corn, a small growing variety, rich in saccharine matter, is used for the table, although common field corn is excellent. The ears should be plucked when in the advanced milk stage, and after boiling about forty minutes should be served with butter, salt and pepper to suit the taste. Often the corn is cut from the cob and boiled with young beans to make the "succotash" of New England. The business of canning green corn has assumed vast proportions in the States; hundreds of factories are engaged in it, and the product is sent to every part of the civilised world. I have myself, in Brisbane, bought canned green corn which had been put up in one of the States of the Atlantic seaboard. Cornmeal is cooked to the condition of "mush," just as oatmeal is made into porridge, and it is eaten as

porridge is usually eaten. Corn "pone" is to the Southern States of America what the damper is to Anstralia—the product of local conveniences and skill, on which account it need not be further explained here. Corn bread and corn cake (which is but corn bread with the addition of sweetings and eggs) are articles of universal consumption in every part of America. These ought to find great favour in colonial homes, where they would be certain to prove a healthful and agreeable variation in the daily bill of fare. Below is given a recipe for corn cake, the excellence of which has been proved in the experience of my own family:—

- 1 pint of corn meal.
 - 1 quart of thick sour milk.
 - 4 eggs.
 - Soda sufficient to sweeten the milk.
 - 2 table-spoonful of sugar.
 - 1 teaspoonful of salt.
- Bake twenty minutes to half-an-hour in a quick oven.

CORN COBS AS STOCK FOOD.

That corn cobs, which in Queensland are universally a waste product, have a very considerable value as stock food has been demonstrated in the long-continued general experience of American farmers. The following table of analyses will serve to show how in chemical constituents the corn cob compares with corn and two common fodders:—

	Water.	Ash.	Albaminoid.	Fibre.	Nitrogen (free extract).	Fat.
Corn	13.93	1.25	8.82	1.59	70.48	3.92
Corn Cob . .	9.25	1.16	1.91	31.22	55.86	0.60
Oat Straw . .	12.50	1.81	2.30	55.96	26.42	1.00
English Hay	14.30	4.70	7.00	26.90	45.40	1.70

These figures do not show the whole value of the cobs as a feed. Cobs are never fed alone, but generally with the corn which grew on them. When fed thus the cob seems to be admirably suited to act as a balance to the more concentrated grain. Moreover, three-fifths of the ash of the cob is potash, an element of undoubted value as an aid to digestion. As a result of my own experiments, made with ten pigs and twenty bullocks, to test the question of the food value of cobs, I found that a pound of corn cob when ground and fed with the corn which grew upon it was worth more than a pound of meal made from corn alone. In other words, both the pigs and bullocks gave better returns from corn and cob meal that was obtained from feeding clear corn meal. Considering the large proportion of ear corn that is cob (18 per cent.), this fact of the feeding value of cobs is a matter of no little importance where, as in Queensland, corn and hay in all its forms have a very high market value. This, however, should be borne in mind; that the cob must be ground fine—quite likely the finer the better—and to grind a given amount of whole ears of corn will require three times as much power, or its equivalent in time, as is needed in reducing the same amount of shelled corn.—*Planter and Farmer.*

PEPPER CULTURE IN PENANG.

The following account of how pepper was planted in Pinang some 90 years ago will be of interest to District Officers in those parts of the State where the natives are vigorously taking up the cultivation of the vine:—

"The manner of Cultivating the Pepper Vine. The result of Personal Experience of a Cultivator, being an Appendix to 'A Short Account of the Settlements, &c., of Prince of Wales's Island, in the Straits of Malacca.' Sir GEORGE LEITH, Bart, Major 17th Foot, and late Lieutenant-Governor. London: 1804." The vines are propagated from either slips or cuttings, and planted in rows at the distance of 6 or 8 feet, varying in this respect according to the judgment of the cultivator. The supporter to the vine is usually planted at the same time, or very shortly

after, the vine. There are several sorts of supporters—the *dedap* and *Mongkudu** trees, are, however, generally preferred; the former, which is propagated from cuttings, is esteemed the best, its spreading branches and thick foliage affording more shelter and support to the vine than the latter, but the uncertainty attending the rearing of it in many soils causes the *mongkudu*, which is raised from the seed without difficulty, to be more commonly used, particularly since the improvement introduced in training it with three or four perpendicular branches instead of one, which was the usual mode; this is done by cutting off the leader when the plant is between four and five months old; this causes it to throw outside shoots, three or four of which only are suffered to remain and trained in a perpendicular manner.

When the vine is first planted it is covered with the branch of a tree called *piah*, something like the *nipah*, to protect it against the effects of the sun, until it has taken root, and is fit to be brought to the stick; this happens usually about six weeks after planting, when a stick of about three inches in circumference, and seven or eight feet long, is planted near it, to which it soon adheres (being first slightly attached to it by a string), and creeps up towards the top.

In eleven or twelve months the vine generally begins to show blossoms, at which period it may have attained the height of six feet: it is then fit for training down; this is done by loosening the vine from the stick and removing that entirely; the leaves are slipped off the stem, leaving only a small tuft at the top; a pit is then dug close to the roots, about twenty inches in diameter, and nearly the same depth at the bottom of which the stem of the vine is coiled horizontally, bringing the top or tuft before mentioned to the supporter already planted for that purpose, to which it is fastened by a string; the pit is then filled, covering the stem in that position.

The increasing size of the vine in a short time after the above operation has been performed shows that roots are springing abundantly from the stem; the whole skill of the cultivator is now shown by the manner in which he trains the vine, as this naturally takes a perpendicular direction; his care is to prevent its ascending too rapidly, which, if not checked, it will certainly do. This was an error the majority of pepper planters fell into at the first settlement of the island, when the cultivation of this valuable plant was not so well understood as at present.

The top of the vine, therefore, and a length of some feet below it, is consequently not allowed to adhere to the supporter, but, being pendant and inclining to the ground, throws outside shoots, by which it increases in bulk proportionably to its height.

Although the blossom on the vine thus turned down comes to maturity, the produce even of the third year is trifling, averaging perhaps, in a large plantation, about an eighth of a catty; from the third to the fourth year half a catty; increasing half a catty a year, until it will average two or two and a-half catties, at which time the vine may be considered to be in full vigour. As there are not many plantations on the island much above ten years old, we can only judge from information how long the vine will continue bearing. From intelligent Chinese, who have lived at Tringano and other places on the eastern side of the Malay Peninsula, we learn that it continues in full vigour to the age of fifteen years, and then gradually declines, still, however, yielding fruit if properly attended to the age of twenty-five or thirty years. This opinion differs very materially from that entertained by the original cultivators on the island, who supposed the vine would cease bearing at sixteen years; there is, however, every reason to suppose the mean of the two opinions will prove nearly correct: a garden eleven years old, situated at Songhy Chuan, containing 3,000 plants only, has lately been let for three years for seventy piculs of pepper per annum, which makes each plant average 2½ catties, a strong

* *Mongkudu*.—A common jungle tree. The Malays make a medicine from its fruit.

argument in favour of the vines bearing longer than sixteen years, as did it then cease giving fruit entirely, the gradual decrease would certainly have commenced at even years: but it has been before observed that the vine in full vigour will not average more than 2½ cattiees per plant. The renter of this garden is thought by his countrymen, the Chinese, to have made a very good bargain.

There are few soils on this island unfavourable to the vine: the dark mould mixed with gravel is generally preferred; it thrives in high and low situations—best in the latter, if sufficiently raised to prevent the water in the heavy rains from settling; if the roots were to be covered with water for six or eight days the vine would infallibly be killed. A plantation, if properly taken care of, should be kept perfectly free from weeds and grass and for the first five or six years the earth should be regularly turned, twice a year; after that period once turning will be sufficient. Four coolies will take care of a laxa (10,000) of plants, if properly attended to; they must, however, be allowed a cook, but they will require additional hands when the crop is gathered; the number will, of course, depend on the fertility of the vines.

The vine blossoms twice a year—after the commencement of the rains in the setting in of the south-west monsoon in April and May, and when they cease in December; the former crop is gathered the latter end of December, January, and February; the latter in May, June and July. The quality of the pepper depends in a great measure upon the care taken in the gathering and drying. The pepper when plucked before it is fully ripe diminishes both in size and weight, so much as frequently to occasion a difference of upwards of 30 per cent between what is gathered in this state and that which attains its full maturity. The Chinese planters fall frequently into this error from want of funds, and the necessity they are often reduced to of realising cash at a fixed period in order to satisfy those who have made them advances at most extortionate interest, and also from a wish to save expense in collecting the pepper gradually as it ripens (which is when the fruit becomes a reddish colour) they pluck the whole or the greatest part of the pepper at once from the vine, instead of those bunches only which are perfectly ripe. This mode of course is more laborious and expensive. When gathered it is exposed to the sun on mats, and in the course of the day begins to turn black; it is then put into a large wicker basket in the shape of a tray, and trod upon to separate the pepper from the stem on which the bunch is formed: in favourable weather it will be perfectly dry in the course of four days, when it is packed in gunnies and ready for the market. A pient of green pepper if allowed to remain on the vines till perfectly ripe will yield from 35 to 36 cattiees when dry.

The vines seldom fail of showing much blossom in gardens which are properly taken care of; but it is subject to be blighted even after the fruit has attained some size when the season proves either unusually hot or dry; when this happens considerable quantities of pepper will drop off: a few hour's rain soon puts a stop to it. The pepper of this island when gathered in a proper state, and carefully dried, is esteemed equal in taste, weight, and size to that of any place whatever, and superior to most. European cultivators make their plantations by contract; the usual price is \$525 per thousand: this includes every expense of tools, houses, digging wells, and clearing the ground, and every other item, the price of the young plant excepted. The pepper plant was first introduced into the island from Acheon by the then Captain China Ke Kay, under the patronage of Mr. Light, who advanced him money for that purpose; this was about the year 1790.—*Perak Government Gazette.*

PEPPER.

I have kept the Resident's instructions with regard to native cultivators in view, and have spent considerable time in discussing with them the merits

of pepper planting, and the profits to be derived from it. I have been anxious to get away from this district to S'tiawan and Batang Padang, but something requiring immediate attention has always turned up to prevent me. I have promised to accompany Mr. Robert Fraser through the land below Hijan and join him tomorrow (Sunday) for this purpose. About the middle of the month I hope to get away for a short time. I have large nurseries of pepper plants, which will be ready for planting in a month or six weeks. I have distributed and sold large quantities of dedap to people proposing to plant pepper. The first difficulty native cultivators encounter is the price of the plants. I wrote fully on this subject to Government in January, and learn from the Magistrate that he has estimated for money for a system of loans in 1891. If the principle is allowed would it be expecting too much to ask the benefit may be extended to those ready to plant this season? I am preparing a list of those who have land prepared and purpose submitting it to the Magistrate. Should he have authority, some good will be done this season, and I will be able to dispose of my plants. This assistance with plants will be a great boon to poor native cultivators, and if they are looked after, with the assistance of their families, they will be able to weed, maintain, and extend their gardens. For carrying on the cultivation on a larger scale, Kon Lin explained the Chinese system to me the other day, and I note it down here as some modification of it may be useful to Government. A party of, say, six labourers L., apply to a capitalist, C., and engage with him for a period of three years to open pepper. C., finds an equal number of coolies (six) S., to work along with L. L. and S. are supplied with provisions by C., the cost of which goes against the estate, E.E. C. pays S. monthly the balance of their wages, about \$6 or \$7, which also goes against E. E. Each individual of L. has a personal account against which goes all cash advances for clothes and luxuries, on which interest at the rate of three per cent is charged for six months only in each year. Buildings, tools, posts &c., are all charged to E.E. At the end of three years the estate is divided, C. takes half L. take half. When the vines come into bearing C. each year buys the whole crop at a sum fixed below the market value, takes one envidided tenth of the whole, and credits E.E. with the balance till the fund is wiped off. Then and not till then L. begin to reap the benefit of their labours. The rule is for each man to open an acre each year, L. finding each a partner after the first year, and applying to C. for extra labour as it is required. In case of dispute, the malcontent's land is valued, and the capitalist buys him out. This is the well known tribute system applied to agriculture. Contrast this with the Malay method on which Syed Musa works—viz., payment of from \$250 to \$275 per orlong for upkeep only till the pepper plants shoot up to eight feet high, say at about two years, Syed Musa paying for everything except labour.—*Perak Government Gazette.*

WITHIN the past ten years the cotton manufacturing industry has made tremendous strides in Japan, the effect of which has been palpably visible in the lessened in-ports of the manufactured stuffs from Lancashire. The *Japan Gazette* gives figures showing the extent of the increased home production in Japan, and from these we learn that in 1881 when the manufacture of cotton goods was budding into an appreciable industry there, the number of mills engaged was 15 with some 30,000 spindles, which, gradually increasing had risen last year to the number of 36 mills, with 258,362 ring frames and 118,860 mule frames while the aggregate capital of the concerns was \$9,019,800, possessing reserves to the amount of \$600,847. So much indeed has the industry developed that fine-woven goods are exported from Japan to India and elsewhere. The demand, therefore, from abroad is diminishing in a correspond-

ing degree in that country. Formerly, our Japanese contemporary says, only the coarser stuffs were manufactured there, the finer ones being imported from abroad, but the necessary plant having been imported both qualities are now manufactured in Japan. As an example of the decrease of imports from abroad of cotton manufactured goods it is pointed out that against the 47,339,636 ounces imported in 1883, only 42,810,912 were imported in 1889, 31,908,802 in 1890, and 23,000,000 in the year just passed. Further than this, the trade was very prosperous last year, and the *Kokkai* says that most of the cotton-spinning concerns in Japan will pay a dividend of from 15 per cent to 20 per cent for the year—*Indian Agriculturist*.

THE AGRICULTURAL SOCIETY OF BURMA.
—A growing interest (says the *Madras Times*) seems to be evinced by the general public in the Agricultural Society of Burma, which is indicated by the frequent references that are made to it in connection with improvements in various branches of agriculture. The Society was compelled last year to abandon the site obtained for an experimental farm at Taikgyi, the locality being found to be one of the most unhealthy on the line of railway. The Society is reported to be now endeavouring to get a suitable plot of land within an easy distance of Rangoon. In 1890-91 filbert nuts were sent for experimental cultivation to Upper Burma, and Liberian coffee plants to Sandoway. In the Society's own gardens experiments were tried with Indian mangoes, which were successfully grafted. American and Upper Burma Indian corn was grown with varying success. Several new varieties of coconuts were imported from the Straits Settlements. Special attention is paid by the Society to raising good and reliable seed of flowering annuals, for which there is a large demand amongst natives of the province. Four hundred young plants of the Area nut palm were procured from Toungoo and Shwegyin and are thriving in the nurseries. During the early part of the year the orchid collectors made successful trips to the Arakan Hills and the Tenasserim Province; several thousands of plants were brought in and sold locally after the conservatories had been stocked. In every way the Society is improving and gathering strength, whether it be in the number of new members admitted, or in the receipts derived from the sale of garden produce. The number of visitors to the Society's gardens and museum is also increasing.

THE COCOA TRADE.—Mr. F. R. Fry, representative of the World-renowned J. S. Fry and Sons, cocoa and chocolate manufacturers, is in the colonies with the object of extending the trade which the old-established firm has built up. On Monday we had an opportunity of chatting with Mr. Fry, and during the interview gleaned some information about the extent of the great cocoa industry. Messrs. Fry and Sons are the oldest and largest house in the business, and to their factories in Bristol go the products of the great plantations of Ceylon, Java, the West Indies, Trinidad, and South America. Cocoa, Mr. Fry says, can be grown successfully in any tropical climate, but he thinks that it is too hot in this continent for the manufacture of the article to anything approaching the perfection to which it is brought in England. The cooler climate of New Zealand and Tasmania might answer, but everything depends, he adds, upon the curing of the cocoa beans. This is the secret of success at the start, and afterwards comes the roasting and blending processes. Some idea of the extent of Messrs. Fry & Sons' business in England may be gained from the statement that there are six factories, employing upwards of 3,000 men, boys, and girls, that the old goal at Bristol

is used solely for nailing the boxes by machinery and timber drying for the box-making branch of the concern, that not long ago £15,000 was expended for refrigerating works, and that four years ago, in order to be in time, the firm applied for space at the forthcoming Chicago Exhibition. Eight years ago they introduced their celebrated brands of "Concentrated Cocoa," a perfectly soluble article with the oil extracted. It is interesting to hear the description, and to see the pictures of the various processes of the cocoa and chocolate making, among others the roasting, the grinding of pure chocolate, the manufacture of the extract, cream-making, fancy-box filling, and the box making, down to the filling of the packets. The trade with the Australian Colonies has extended rapidly of recent years, in fact, the taste of cocoa has been cultivated to such an extent that there are now but very few houses in time, at some part of the day or other the cocoa is not used as a pleasant substitute for tea or coffee. Mr. Fry sees no reason why cocoa cannot be profitably grown in the Northern Territory, where it is proposed to introduce the plant, and then sent to the home markets. It is estimated that the yearly consumption of cocoa at the present time is upwards 20,000,000 lb.—*S. A. Register* (Adelaide), Feb. 16th.

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE,

COLOMBO.

Added as Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for April:—

INSECTS AND INSECTICIDES.

THE Agricultural Conferences lately held in Queensland have been the means of bringing together many Agriculturists and men of Science, whose utterances, spoken with authority, have been embodied in a report issued by the Brisbane Department of Agriculture. At one of these Conferences Prof. Shelton delivered himself on the subject of insect pests, and a good deal of the learned Professor's advice on this head is worthy of consideration. All insects might be said roughly to get their food by only two methods—either they are provided with beaks or sucking apparatus which they thrust into the bark of a tree and draw the juices to themselves, or they have powerful jaws and teeth, and gnaw into the substance of the tree, or the leaf as the case may be. It is important to remember that this difference most materially affects man's method of treatment and handling. The scale insect, which adheres to the leaf and sucks the juices plainly cannot be got at with poison in the same way as the other which gets into the substance of the leaf and consumes it. In a general way the insects which gnaw could easily be reached by some poison thrown on the leaf itself, so that when it consumes the leaf it also takes the poison and is killed. In the case of the sucking insects, something must be forcibly thrown on them, which in itself is fatal by contact, and the great agent used for this purpose in some form or other, is kerosine—in fact kerosine is the best agent for this class of insects, and London purple or Paris green for

the gnawing insects. There are of course many other ways of accomplishing the work of destroying insects, but none so satisfactorily as those mentioned. Paris green is an arsenical poison, a waste product occurring in the manufacture of aniline dyes, and poisonous in the same sense as arsenic. Arsenic might be used in place of it, but for various reasons it is not safe. Paris green, owing to its colour is not likely to cause accidents as arsenic through being left about. London purple, another arsenical insecticide, is made in a like manner to Paris green, but it differs slightly in composition, and is cheaper and stronger and goes a little further in fact. Prof. Shelton considers it generally better than Paris green. These insecticides, which could be ordered through any chemist, might be used in two different ways. The common way is to take 1 lb. of Paris green and dilute it with 150 to 200 gallons of water. The green will not dissolve, or very slightly, and the mixture could be distributed with a can, only care should be taken to stir it frequently so that the powder may not settle at the bottom of the can. Again, the mixture might be scattered all over a tree by means of a force pump. Another way of using the insecticides is to take Paris green or London purple and mix it with 12 parts of fine dust, flour, ashes, plaster of Paris, or lime, put it in a piece of suitable cloth (so as to allow the powder to pass through readily), tie it up, attach it to the end of a stick, and walk along between the rows, shaking the dust on the plants. This is sure, says Prof. Shelton, to kill every insect that exists there. This should be done, if possible, in the early morning, when the dew is on the plants. Some prefer to use a syringe and a can to be fastened to the back, and distribute the poison diluted with water. In the case of potatoes, Prof. Shelton did not think that either Paris green or London purple was injurious to the plants themselves, and states that they could be applied with the absolute assurance that the potato would not take enough of it to influence the plant itself.

He mentioned, however, that he would be careful in using it on cabbage plants, which were eaten whole, and which grew rapidly, because if the fine powder settled around the leaves there would be real danger: with young plants, however, there would not be the same risk, and the slugs that feed on them would be killed instantaneously. The cotton worm can be totally destroyed in the manner described. In the case of cotton, by the use of a pole with bags of the powder on either end, a man, walking between the rows and giving the pole a shake now and then, would deal with 8 or 10 acres in a day. All this refers to the biting insects.

With the other class, to which the various scales belong, Paris green is perfectly helpless, for the simple reason that we cannot get at them with it. The universal remedy for this class of insects is kerosine in one form or another. The moment kerosine strikes it kills, but unfortunately it often kills the tree also—the leaves get scorched and soon drop off, and great damage results. Hence kerosine must be diluted in some way, and put into a shape in which it can be applied to the tree without injury and yet kill the pests. To overcome this difficulty a good many remedies have been proposed, but the best form in which to apply the insecticide is kerosine emulsion, which has been tried in all parts of the world with success. The following is the recipe for its manufacture: Take first a quart of common soft soap, or $\frac{1}{2}$ lb. of hard soap (the former is preferable), add 2 quarts of boiling water so as to thoroughly dissolve the soap, and then put one pint of kerosine. If possible a pump should be used to churn the mixture, till the water, kerosine and soap are thoroughly intermixed. When left standing for a time, if the soap be good, no scum of kerosine should rise to the surface. Now add cold water to make, altogether, about 15 pints of the material—that is to say, 1 pint of kerosine to about 14 or 15 pints of the other ingredients. This could be applied to a tree, says Prof. Shelton, with the absolute certainty that it would do no damage, and it is strong enough to kill almost all kinds of scale insects. But the application of the emulsion is of the utmost importance, and those who have found it a failure, did not apply it as they should. All contact poisons must be applied forcibly; the insect must be struck vigorously. This is true with nearly all scale pests, and one application does not always do. If one be found insufficient, another must be given in one or two days, or one or two weeks' time, as the case may be. By thorough syringing a tree could be rid of all or nearly all insects, but patience and labour are necessary. There are a multitude of machines for applying this emulsion, but a pump with a cyclone nozzle which would produce a mist-like spray of soap and kerosine is one of the best means. By fixing the nozzle beside the trees with the hose over his shoulder, while the other walked behind with a bucket, a big orange tree could be syringed in about 3 minutes.

In view of the enormous extent of damage done by insects to all kinds of crops in Ceylon, it would be of immense benefit to our culti-

vators if facilities were given for the carrying out of a series of experiments on the lines of the systems which Prof. Shelton describes as being so successful.

OCCASIONAL NOTES.

In the *Kew Bulletin* for January 1891, there was discussed in some detail the origin of the preserved ginger from China. From species of living plants received at Kew from Her Majesty's Consul at Swatow, it was concluded that the plant yielding Chinese ginger was something different from the ordinary ginger plant (*Zingiber officinale*). The prominence given to the subject in the *Kew Bulletin* led to further investigation, and the fact would appear now to be established that Chinese ginger, in spite of the superficial difference in the appearance of "the large flat finger-like masses" as compared with West Indian and other commercial ginger, is undoubtedly produced by *Zingiber officinale*. The plants sent by Her Majesty's Consul at Swatow belonged to *Alpinia Galanga*, and were the cause of misleading the authorities at Kew. It is thought that the Consul, while endeavouring to render a useful service, was the innocent agent of a wrong conclusion having been arrived at, through the natives, who supplied him with the plants, which were sent to Kew, having bought in the wrong kind.

Mr. Samersekere, the Agricultural Instructor at Kadugamawa, reporting the result of his paddy cultivation for the Mahn season 1891, says: One acre transplanted with seedlings raised from quarter-bushel yielded a crop of 39 bushels; three-quarters of an acre sown broadcast with Ma-vi gave a crop of 25 $\frac{1}{2}$ bushels, an average yield of 36 bushels per acre. The neighbours according to their system obtained 29 $\frac{1}{2}$ bushels from 2 acres with 5 $\frac{1}{2}$ bushels of seed paddy, and 20 bushels from 1 $\frac{1}{2}$ acre after using 3 $\frac{3}{4}$ bushels of seed. The total yield of my 1 $\frac{3}{4}$ acre is valued at R80-62 $\frac{1}{2}$, and this deducting cost of expenditure, leaves a profit of R56-25.

A sprinkling of bone-dust was used in a portion of the field where the seed was sown broadcast. The seedlings that were planted out suffered much from the rains that followed the transplanting, and some of the plants consequently flowered late and produced bad ears. The following will give the full details:—

	Extent sowed.		How much seed used.	Cost of cultivation.	Crop.	Bushels per acre.	Amount of sale.	Profit.
	Ac.	Bu. R. c.						
<i>Instructor:</i>								
Planted out	1	$\frac{1}{4}$	23 37 $\frac{1}{2}$	39 39	25 $\frac{1}{2}$ 33 $\frac{1}{2}$	880 62 $\frac{1}{2}$	56 25

Seed Paddy	3	00
Reaping, Threshing and Winnowing $\frac{2}{3}$ acre	2	50
Do do do 1 acre	3	50
Total.	R23	37½

Mr. Samaresekere also reports the results of his cultivation at Ellawala for the Maha season 1891. He states that the whole extent of land prepared according to the improved system was sown broadcast (but much thinner than the ordinary sowing of the goiyas), with 3½ bushels of goda-ma-vi seed paddy, which gave a return of 45½ bushels—an average yield of 22¾ bushels per acre. The neighbours obtained 15½ bushels from 1½ acre, using 3½ bushels of seed, and 26 bushels from 2 acres with the use of 4 bushels of seed. The total yield of my 2 acres is valued at R56.87½, which, after deducting cost of expenditure, leaves a profit of R28.62½. No manure was used in this case. The following are the details:—

	Extent sowed		How much seed used.	Cost of cultivation.		Crop.	Bushels per acre.		Amount of sale.		Profit.

The process of Kitul-toddy drawing is a far more intricate one than that of extracting toddy from the coconut palm, and the details of the process are more or less a secret with the professional toddy-drawer. Though there is a tolerably large number of kitul palms in and around Colombo, few if any of the trees seem to be tapped for toddy, and it appears almost impossible to procure a man who would undertake to extract toddy from kitul trees within the limits of the town. This has been our experience in attempting to secure the services of a man for a gentleman in Colombo. Kitul toddy drawers can, however, be persuaded to come into Colombo from along the south road, provided their services are engaged for a little time by the month. The wages of these men

are usually reckoned as the value of half the amount of toddy extracted by them, or this amount of toddy itself. A correspondent writing from Subaragamawa asks that some of our contributors should treat of the subject of kitul and coconut toddy extraction in these columns. In the paper on the kitul palm which is being contributed by Mr. T. B. Kehelpanela, the former process will be dealt with, and we have no doubt but that Mr. Atherton, who has so ably written on coconut cultivation, will take up the extraction of toddy from the coconut palm before he abandons his subject.

Reference has already been made to a work on cattle-keeping lately published in Calcutta, and a review of this useful work has already appeared in the *Ceylon Observer*. The only drawbacks in the adoption of the treatment for cattle diseases, recommended by the author, are that the English remedies are all homœopathic preparations, and that the names of the native remedies are given in Hindustani or other Indian language, no botanical names for trees and plants being given. To those who possess the book, therefore, and to such as intended to adopt the treatment recommended by its author, some information on the signification of the Indian terms occurring in the work referred to will, we think, be welcome. Mr. L. E. Blazé (now of Kandy), who spent many years in North India has been kind enough to give us this information as supplied to him by Mr. Andrews, Assistant Superintendent of the Lahore School of Arts, and Mr. Kipling, the Superintendent of the same institution.

Shimul cotton tree=*Bombax Malabathricum* (the Sinhalese Katu Imbul), the silk cotton tree, a large handsome tree common in India and Burma, the largest and most characteristic tree of Eastern Rajputana, produces a jelly-like gum (mócharas) from a diseased condition of the bark; also, on the seeds, a fine silky cotton-like fibre used for stuffing pillows, and for making gun-cotton.

Bhoosa=chaff, broken straw after threshing.
Khully=oil cake.

Doob grass=*Cynodon Dactylon*, the most nutritious and useful fodder of India, sometimes called Mariali grass,—the couch grass of Australia and America.

Gargion, no doubt Gurjun or Kanjin oil, a wood oil from *Dipterocarpus turbinatus*, used for many diseases (e. g., leprosy) both internally and externally, also as a varnish, for lithographing ink, &c. is a solvent of Indianrubber. Acts as a substitute for linseed oil, but dries slow and is thin in body. (*D. Turbinatus* is found in Ceylon.) Chirchery would seem to be *Achyranthus Aspera* (the Hindustani Lalehicheri), the Sinhalese gas-karral-habba. Jokha, probably Gokhoor (*Tribulus languginosus*). This is also known as *T. terrestris*, and occurs in the north of the island.

With regard to the system of weights used in the above work, the following will be a guide:—
12 Masha = 1 Tola = 7 dwt. 12 grs. Troy.
5 Tolas = 1 Chittack = 1 oz. 17½ dwt. do
16 Chittacks = 1 Seer = 2½ lb. do
40 Seers = 1 Maund = 100 lb. do

From all accounts "Malignant Sore Throat," a very fatal and highly contagious diphtheretic affection, is prevalent in the North-Central Province.

Mr. H. D. Goonesekere has been appointed Agricultural Instructor at Balangoda. He is in charge of the Impulpi and Bowatha Schools.

THE CULTIVATION OF THE COCONUT PALM.

In dry seasons, generally, it very often happens that the manager of a coconut property, in walking along his boundaries, will notice the portions nearest to any jungle, presenting a very strange appearance. The drooping fronds of the palm will be covered with a greyish substance, and in a few days the greater portion of the leaflets will disappear, leaving behind only the midribs. As time goes on this appearance will be assumed by other trees, and the 'disease' will be found to be spreading, till the major portion of the estate is in the condition above described. This is due to the coconut fly or coconut worm attacking the palms, and it is well if the attack be noticed early and remedial measures be taken, for an estate thus affected will lose its young nuts, and the proprietor get no returns from his property for one or two or even three years to come, according to the severity of the attack. An estate affected by this insect presents a sorry sight—the green leaflets turned to an ashen hue, the ground strewn with young nuts. The mode of dealing with the pest (namely by smother burning with the object of smoking out the insects) has been referred to already in my contribution which appeared in the February number of the Magazine. I will add that it is indeed well to smoke not only the infected lines but also the unaffected rows for some distance, so as to make sure there are none of the insects left alive in a yet dormant state. The conformation of the leaflets of the palm favours the security of the enemy, which safely esconces itself on the under side of the leaflet, firmly lodged in the apex of an inverted V, unaffected by wind or rains, feeding as it grows on its leaf covering. But when the acid smoke ascends from below, its domicile is invaded, and it cannot do otherwise than drop helplessly to the ground under the influence of the smoke. It will thus be seen that the heaping up of dead branches along each second row—and keeping up the supply—in districts liable to attack from this insect, becomes a paramount necessity, and a foreseeing manager will always leave a well here and there to supply water for sprinkling the burning heaps, in case of necessity. If the pest does not make its appearance, the heaps of withered and dead leaves will soon decompose into a mould, which is as good as any manure for a coconut tree. Mr. Muuro, whom I have before referred to, after liquid-manuring his trees, covered over the manured parts with this decomposed stuff and earth, and laid dry branches over the heaps. This was done to keep the roots cool and prevent evaporation from the liquid manure.

In the Eastern Province there is another visitation to which coconut trees are liable, known as "Colai Thongi" among the natives, meaning "dropping bunch." Quite suddenly a remarkably fine cluster of nuts is seen to hang, inert, from the branches, and the nuts begin to look sickly. On many estates the bunches were supported artificially by rattans, which are attached above to the crown of the trees, but this was found an expensive method. Nuts, affected thus, either fall off without properly maturing, or they shrivel up to half their natural size.

Estates surrounded by high jungle will, in their early stages, be damaged by monkeys and large red or grey squirrels as well as the small striped ones. Hundred of nuts are found on the ground with large holes bitten into the crown by monkeys. The only remedy is frightenning away the animals, or shooting them, with a gun.

Trees which die under attack of red beetle should be cut down, burnt and buried, as their remains harbour worms and their eggs. The black beetles can be impaled on needles made for the purpose, the process doing no harm to the trees. There are hundreds of trees existing that have been drilled in the process of beetle extirpation, and these bear as well as ever they did.

Some trees never bear nuts, and others bear only light nuts called "ollies." The late Rev. J. Kilner informed me that in the Northern Province, such trees were rendered fruitful by cutting out a ring out of the stem with a chisel. I have never put this remedy to the test, but have succeeded in making bad trees bear by having them tapped for toddy. It is possible that by inducing the outflow of an inferior sap during the process of drawing toddy, the tree is given an opportunity of elaborating a superior sap afterwards.

Coconuts are here plucked by means of long bamboo poles to which a hooked knife or "cattie" is fixed; but as this cannot be done in the case of very tall trees, the nuts of these are allowed to fall naturally. Picking may be said to go on constantly and copperah manufactured, except in the rainy months, November to February. At these seasons, however, the nuts keep falling from the trees at the rate of several hundred every day.

R. ATHERTON.

INDIGENOUS FOOD PRODUCTS: CULTIVATED AND WILD.

BY W. A. DE SILVA.

Amarantaceae.

(Erratum. Read *Amarantus Spinosus*, L. for *A. Speciosus* in Section 66, p. 64.)

67. *Amarantus Polygonoides* L. Sin. Kūratampalā.

Is an annual low herb growing in waste and cultivated lands where the soil is fertile. These plants have an abundance of small green leaves with pinkish midribs and petioles on their stems. The leaves and the tender parts of the stem are used as a food in the form of a curry, and is much relished; but the plant cannot be easily obtained in any large quantities, and it is seldom that it is exposed for sale in the markets.

The Indians consider this plant a very wholesome food, especially for convalescents.

68. *Æra Lanata*, Juss. Sin. Polkudūpalā.

This plant is found growing in the warmer regions of the Island in open places, where the soil is fertile. It is a low herb, much branched, consisting of small green leaves which are covered with a pubescence. The spikes are crowded together and are found at the axils of the leaves, and the flowers are white. This gives a peculiar appearance to the plant, as if it were sprinkled over with a white powdery substance, and the Sinhalese name Polkudūpalā signifies its outward appearance — *polkudu* being the white refuse of scraped coconut kernel, and *palā* herb. The plant is not very abundantly met with, and hence it is difficult to collect it in sufficient quantities to use it as a food except on rare occasions, when a dry curry is prepared which is much relished. *Æ. Lanata* is largely used in medicine, and is reputed to possess very beneficial properties. The roots of this plant are said to be employed by Indian medical practitioners as a demulcent.

69. *Alternanthera Triandra*, Lam. Sin.

Mukunuwenna.

Grows abundantly in rich moist situations and is rarely found in a poor soil. It is a small herb, much branched, and grows prostrate on the ground. The stems are very thin and of a pinkish colour, whilst the small leaves have well marked veins of a pinkish colour. The short spikes are borne at the axils of the leaves. The plant, wherever collected, is relished as a food in the form of a dry curry, and is much sought for both on account of its peculiar pleasant taste and its reputed medicinal properties. Native medical practitioners prescribe it in cases of vertigo and complaints of the head as a cooling local application, while the curry is said to be effective in cases of indigestion.

KITUL PALM (*CARYOTA URENS*).

Description.

The Kitul palm is known as the Jaggery palm or wine palm. It is also frequently termed bastard sgu palm, as it contains starch in its stem. The Kitul is scientifically termed *Caryota Urens*, and belongs to the order *Palmaceæ*. The trunk is erect and cylindrical, and attains a height varying from 30 to 60 feet, and the leaves are marked with sharp indentations. In describing this ornamental palm, Rev. S. Langdon in his book entitled "My Mission Garden," says, "One of the most interesting palms in the garden, and one of the most beautiful, is the Kitul (*Caryota Urens*). As we stand under the shade of these graceful trees, we begin to realise what Tennyson means by the 'Imbower'd vaults of pillar'd palm.' The stems are among the finest columns to be found in all nature's forest architecture, while the feathery capitals have never been rivalled in the structures raised by man." A characteristic feature in this useful palm is the bringing forth of flowers in a regressive form. The topmost flowers spring first and then the

tree ceases growth. Other flowers springs out in the next season from the axil of the next leaf below the top. In this manner flowering is continued till the axil of the lowest leaf is reached. The tree at this stage loses all reproductive power, becomes totally barren and gradually dies a natural death.

(B). *Growth.*

The Kitul palm is found both wild and cultivated in most parts of the Island, but it thrives most luxuriantly and most abundantly in the Southern and Central parts of Ceylon. I have had ample opportunities of observing that the trees which grow on high elevations are generally less flourishing than those on low lands. There are male and female trees, but we also find both the organs in the same flower. It is not an uncommon sight to see 10 or 12 Kitul trees in every garden of a Kandyan villager; but sometimes over 100 trees are found growing in each garden. The Sinhalese seldom or never cultivate this palm in the proper sense of the word. Kitul fruits when ripe assume a reddish appearance, and the epicarp contains saccharine matter which is much relished by the wild cat. The mesocarp contains a white pulpy substance. The wild cat eats this fruit and the tree is commonly propagated by the animal dropping the seed with its fæces. Owing to the fruits being propagated in close proximity to each other, the fertility of the tree is impaired, and if the villagers were to root up the germinated plants and replant them at prescribed distances, the fruitfulness of this palm would be remarkably increased.

(C). *Uses.*

Next to the Coconut (*Cocos nucifera*) and Palmyrah (*Borassus flabelliformis*), the *Caryota Urens* can be put to the greatest variety of uses. The tree yields a very durable timber, which is largely utilized for making pestles, beams, rafters, laths, water pipes for native houses, walking sticks, door frames, window posts and railings. The price of a hundred laths of 10 feet each is about R4, while of a hundred rafters of 10 feet each, about R7-50. The leaves possess a fair percentage of water, and are much relished by the elephants. The tender leaves are characterised by certain medicinal properties, and are used in preparing a conjee which is given to invalids as a febrifuge. The leaf buds are also boiled and given to patients as a preventative against giddiness. The roots and barks constitute an important medicinal ingredient for snake bite, while the midribs are extensively utilized for fishing rods. The fibre, which is found at the base of the leaf stalks is made into excellent rope by the Rodiyas or the lowest class of Sinhalese. These ropes are very strong and durable, and are used in tethering cattle and for other purposes. The fibre is, moreover, made into brushes and also used as stuffing material. According to Mr. Jackson, who has published a book on "Commercial Botany," the fibre has taken a prominent position in the brush trade in England, where it has been known for the last 30 or 40 years, but it is within the last 5 or 6 years that it has become a regular commercial article. It appears that this fibre is steeped in linseed oil to make it more pliable and for darkening it. It can

also be used either alone or mixed with bristles in making soft long-handled brooms, which are extremely durable and can be sold a third of the price of the ordinary hair broom. The use of this well-known Ceylon fibre is said to be spreading not only in England, but also on the Continent.

T. B. POHATH KEHELPANNALE.

School of Agriculture,

March 16, 1892.

(To be continued.)

NOTES FROM A TRAVELLER'S DIARY.

Owing to my multifarious duties, I have only just been reading the account of the Prize-giving ceremony at the Colombo School of Agriculture in December last. I must confess that I am one of those who at first had grave doubts as to the need and success of this institution, and the amount of good it was likely to do. In my own case as well as in the case of others, this was owing to want of experience and ignorance of the requirements of the Island. Since, however, my duties have imposed upon me the necessity for travelling over a large area, I have seen much of native agriculture as it is practised in the villages, and the more I see of the work of our native cultivators, the more am I convinced of the necessity there exists for demonstrating to them the fact that their lands could be more profitably utilized, both by adopting better systems of cultivation and by growing food-producing crops of which they are quite ignorant. Such a consummation could only be secured by giving the younger generation of the land-owning and cultivating class a systematic training in the science and practice of agriculture, and Agricultural Schools and institutions are thus indispensable for the future welfare of the natives of Ceylon.

A striking example of the influence which an improved and intelligent system has on the minds of native cultivators, is seen in the case of modern coconut cultivation. On comparing some of the old coconut gardens of the interior with a modern estate, we find the trees in the former planted far too close, with little regard to order, no thought being taken of the growing or feeding area of the plants. In these old estates no such thing as a selection of seed nuts was even thought of, and the result is that only a proportion of the palms are good producers. The evil consequences of such injudicious modes of cultivation are now too well known, and require no further comment. But even at the present day we find places in the far interior of the Island to which the influence of an improved system of culture has not permeated, and where ancient and rude methods are still adhered to. In a place called Kebiligallewe, about 50 miles from Anuradhapura, I was astonished to find people engaged in planting coconuts about 5 feet apart and with no regard to order. This does not show that our cultivators know all about Agriculture, and that there is nothing new to teach them!

When I first began expressing my animadversions on agriculture in these columns, and referring to the requirements of the different places I visited in the course of my travels, I pointed out the difficulty of directly reaching the older cultivators so as to influence them, and said that the only means of getting at them indirectly was by teaching the young generation. This has been the object of the School of Agriculture at Colombo. But I am glad to see that greater facilities are about to be given for the carrying out of this intent, and that a class for training teachers has been opened in connection with the Central School of Agriculture, so that our future Schoolmasters will go abroad with a knowledge of agriculture in addition to their other acquirements. This idea of the Director of Public Instruction redounds greatly to his credit and will bear good fruit.

FOREST PRODUCTS. II.

Among the products which might with advantage be collected from the forests of Ceylon, apart from the different kinds of timber, may be mentioned a large variety of fibres and jungle ropes, gums, resins, tanning barks and fruits, dye stuffs, oil seeds and medicinal herbs. These substances though not found in any great abundance, would, if systematically collected and profitably disposed of, not only be a means of earning a living to many a villager, but may develop other industries, suited to the people, who will possess the raw materials.

The species of plants which yield fibres or which provide jungle ropes are many and varied. The cost of preparation or the separation of the fibres might be prohibitive in some cases, while in the ease of others there might not be a demand. Still, there are a few, easy of manipulation, likely to give very good results and command a ready sale. Among the fibre-yielding plants growing wild in Ceylon may be mentioned,

Caryota urens, L. Sin. Kitul palm.—The Kitul fibre, a valuable product, is obtained from the leaf stalks of this plant. This fibre is largely exported from Ceylon, and is used for making ropes, brushes, brooms, &c.

Agave Americana, } American Aloe plant.
Fourcroya Gigantea }

Sin. Goni.—These plants might with advantage be grown extensively on the borders of the forests. They are just now used as hedge plants in Ceylon and India, and are easily propagated. They yield a strong fibre. The fibre prepared from the flower-stalk is said to be made into costly lace.

Musa. Sin. Kehel.—The wild plantain which grows abundantly in some districts gives a very fine fibre from its leaf stalks.

Sansevieria Zeylanica, Willd. Sin. Nyanda.—The fibre obtained from the leaves of this plant is also known as Moorva or Bowstring Hemp. It is of an excellent quality and fetches a good price. The plant is abundant in the hotter parts of the Island.

Hibiscus Ficulneus, L. Sin. Kapukanissa.—A low shrub, the bark of which yields a fine fibre.

Hibiscus Liliaceus, L. Sin. Belipatta.—This plant grows abundantly and sometimes to large dimensions in the vicinity of streams and water-courses, and is also a common hedge plant. The bark (liber) of this yields a very strong fibre suitable for ropes, &c.

Sida. Sin. Bebila.—The various species of *Sida* yield a fibre from their barks.

Urena Lobata, L. Sin. Patta Epla.—This shrub grows abundantly in the warmer regions of the Island, and yields a very strong liber suitable for cordage.

Morocarpus Longifolius. Bl. Sin. Gas dúl.—Is a tree yielding a fine fibre from its bark.

Boehmeria Malabarica, Wedd. Sin. Mahadiyadúl.—From the bark of this and other members of the nettle, fibres are obtained.

Anodendron Paniculatus, D. C. Sin. Dúl.—Is a climbing shrub, and the fibre of its bark is very fine and strong.

Allanthus Zeylanicus, Thw. Sin. Allandugaha.—A very tough fibre is obtained from the bark of this plant.

Antiaris Innornia, Bl. Sin. Ritigaha.—The fibrous bark of this tree is separated as a whole, and is used as sneks by the Veddhas and other people living in the interior districts.

Gyrinops Walla, Gaertn. Sin. Walla.—Grows abundantly in the warmer regions and yields a strong white liber.

Lasiotiphon Ericcephalus, Deene. Sin. Naha Gala.—The bark yields a fine fibre.

Triumfetta Angulata, Lam. Sin. Appela and other species of *Triumfetta* yield fibres.

Grewia Orientalis, L. and other species (Sin. Danumya) yield a fibre from their barks.

Entada Scandens, Sin. Puswel.—Is a strong jungle rope.

Derris Uliginosa, Benth. Sin. Kalawel.—Yields a jungle rope.

Ptillostigma Racemosa, Benth. Sin. Mylagaha.—Yields a tough fibre from its bark.

Phoenix Sylvestris, Sin. Indi.—Yields a fibre from its leaf stalks.

Nepenthes Distillatoria. Sin. Bandurawel.—Yields a strong jungle rope.

W. A. D. S.

GENERAL ITEMS.

Sir James Caird, K.C.B., LL.D., F.R.S., died on the 9th of February. It will be recollected that he was appointed on the Famine Commission to enquire into the circumstances of the great Indian famine of 1876-7. Sir James was the author of several works on agriculture, which passed through numerous editions, and were translated into foreign languages.

The *Egyptian Gazette* of February 17th contains a report on the Tewfik College of Agriculture, Gheezeh, by Mr. Williamson Wallace, who is the Director of Agriculture in Cairo, and a brother of Prof. Wallace of Edinburgh University. From it we gather that the College possesses a Director, Sub-Director, 5 Professors and 2 Lecturers, and 64 Students, and that a farm of 235 feddahs is attached to the institution, which also has a Chemical Laboratory, Veterinary Museum, Library, &c. The following are the subjects embraced in the four years' course: Agriculture, General Chemistry, Practical Chemistry, Agricultural Chemistry, Botany, Geology, Veterinary Science, Gardening, Entomology, Land-Surveying, Practical Gardening, Practical Agriculture, Book-keeping, and the Arabic and English languages.

The Mawal (*Bassia Latifolia*) plants presented by Mr. J. P. William (seedsmen) to the School of Agriculture, are coming up well. One plant put into almost a pure silicious soil is flourishing as well as the rest on a better soil.

According to the *Produce Markets' Review*, the Government of the United States is most anxious to introduce Indian Corn among the ordinary foods of Europe, so as to find an export outlet for the vast home crops which are three times greater than the immense wheat produc-

tion which has revolutionized the trade. The following figures show the production of cereals in the States: Indian Corn 76,204,000 acres producing 2,060,154,000 bushels, Wheat 39,917,000 acres producing 611,780,000 bushels, Oats 25,582,000 acres producing 736,394,000 bushels. Few people have an idea of the enormous consumption of maize in America. It is also one of the principal articles of diet in the South of Europe. Indian Corn is of course well known in the shape of corn flour and hominy, and is a cheap and most nutritious food, and makes good bread mixed with a certain proportion of wheat flour.

Within the past few years, says the *Indian Agriculturist*, the Cotton Manufacturing Industry has made tremendous strides in Japan, the effect of which has been palpably visible in the lessened imports of the manufactured stuffs from Lancashire. Both finer and coarser stuffs are now manufactured and exported to India.

Apart from the question of purity, the nutritive value of milk depends to a great extent on the nature of the food given to cows, and it would be a perfect system that would ensure to purchasers of milk the fact that the cattle which supply their milk are allowed a diet calculated to produce milk of good nutritive value. As the result of careful experiments at the Iowa Agricultural Experimental Station, it has been found that the kind of food had a decided and material effect upon the quality of milk produced as regards percentage of fats and solids: the rations compared produced an average difference of over $\frac{1}{2}$ lb. of fat and nearly $\frac{3}{4}$ lb. of solids per 100 lb. of milk.

A first shipment, consisting of the major part of the exhibits from Ceylon, has been made to London for the Imperial Institute. The remaining exhibits will be despatched very shortly, and Dr. Trimen, who has undertaken the arrangement of the collection in London, follows about the middle of April.

At the March meeting of the School of Agriculture Improvement Society, a paper on the "Kitul Palm" was read by Mr. T. D. Kehelpanella. The subject for the next paper is to be the Palmyra Palm, the reader Mr. Nallatamby.

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. XI.

COLOMBO, MAY 2ND, 1892.

[No. 11

DICTIONARY OF MATERIA MEDICA.*

NE of the characteristics of a true-born Briton is said to be an innate love of physic.

Whether this be true or not, it is certain that a large proportion of the British public are habitual medicine-consumers.

Excluding those who have no choice in the matter, and who passively swallow whatever is prescribed for them, a good many it is well-known are only too fond of experimenting on themselves without leave or license from any orthodox authority, especially since the homœopathic craze has rendered amateur doctoring so easy. They believe only too readily every puffing advertisement of every patent "certain cure" if it be only judiciously backed up by pretended, or, it may be, genuine testimonials from patients who had been in *extremis*, or had gone the round of the faculty without experiencing any benefit, or had been bedridden for 20 years, &c. &c.; and the very victims who are thus deluded become unwittingly the baits with which new traps are set for the unwary. Only let two or three of the leading members in a community be persuaded—it does not matter by what means—to use a quack drug, and its success thereafter, as regards the general public, is only a matter of time. Now it is not quite so difficult a thing as some believe to "catch your hare," to secure a few prominent men, in order to puff a quack article into notoriety. The ignorance shown by so-called educated men in such simple matters as the structure or functions of their internal organs, the laws of health and disease, the processes by which morbid conditions are overcome, the mode in which medicines act in aiding, altering, or counteracting these processes, is so extreme, that the quack who is only too cognizant of this fact, as well as of the child-like credulity which most men evince in matters with which they are not familiar, is ready to take advantage of such ignorance and simple faith, by clothing his appeals to their vanity and self-conceit, or it may be to their avarice and self-interest, in a tissue of scientific jargon and cunningly disguised fallacies, which seldom fails in its object. It is so pleasant to think that one can at a bound scale the heights of medical knowledge which the orthodox disciples of Æsculapius have reached

only after a toilsome life-long journey, or per-adventure have not reached at all. So pleasant, for instance, to correct any indiscretion one may have been guilty of in diet or drink, and to stave off the symptoms of a congested liver, or the warnings of an impending fit of rheumatism or 'gout, by a dose of Cockle's Pills or Mother Sairey Gamp's Syrup, unfettered by the vexatious restrictions on one's favourite tipple which the ordinary medical attendant imposes as a rule when he assumes charge of the case. And besides there is no question but that some of these quack remedies do sometimes benefit some patients. Most of these infallible cures have an aperient action; and there are few diseases which are not relieved at some stage by aperient medicine whatever its composition. Others again get well while using these remedies, and even in spite of them, thanks to the wonderful self-reparative, self-restorative powers of nature. But as there is no fallacy which so easily imposes on the lay mind—or on that matter on the professional mind when untrained to logical reasoning—as the *post hoc ergo propter hoc* fallacy, the cure is attributed to the remedy last used, and thus new advocates are gained to plead in its favour, new testimonials made available to puff it into still further notoriety. *Populus vult decepti et decipiatur*. The public had themselves to deception only too readily. Hence the enormous fortunes made by men like Holloway, Merisen, &c. Hence too the astounding fact that no less than £225,701 was received for stamps on patent medicines alone last year by the Inland Revenue authorities; an amount which, considering that the stamp on a shilling bottle or box of medicine is only three-halfpence, represents some millions of bottles annually sold to the public in the United Kingdom only.

But the craving for medicines is not confined to the British public. It exists everywhere, and indeed seems instinctive with all races. Drugs of some kind seem to have been a necessity from all time—as imperative almost as food. Rhubarb is mentioned in a Chinese book 2,700 a.c. and a fragment of a cuneiform Babylonian inscription deciphered by J. Halévy (Records of the Past, Vol. XI. p. 159, London, 1878) shows that at least a thousand years before the time of Moses and the first recorded notice on the subject of medicine in the Bible (Exodus xxx, 25, 35) the Babylonians or rather the Accadians had already attained a considerable amount of pharmaceutical knowledge.

One would have to go very far back indeed into the history of the past to trace the origin of physic. Most probably it was instinctive (hence the supernatural origin ascribed to it by the earliest nations), just as it is at the present day among the lower animals. Dogs it is well-known have their hereditary knowledge of herbals. In most folklore stories various animals are believed to have a special knowledge of remedies for various diseases and injuries—especially antidotes for poisons, &c. It is by imitating them perhaps that man gradually came to acquire a knowledge of the medicinal virtues of various plants. Chance and observation and experiments added to the original stock from time to time, while with the extension of commerce and international

* Dictionary of Materia Medica and Therapeutics. A Résumé of the Action and Doses of all Official and Non-official Drugs, with their Scientific, Common and Native Names and Synonyms, and in many instances their French, German and Indian Equivalents. By C. Henri Leonard, A.M., M.D., and Thomas Christy, F.L.S., etc. London: Baillière, Tindal and Cox, publishers, 20 and 21, King William Street, Strand, London 1892.

trade and intercourse, and the development of natural science, botany and chemistry chiefly, still further additions were made, and are being daily made to the Pharmacopœia of each nation, until at the present day, notwithstanding the process of elimination which is constantly going on of every article in the *Materia Medica*, which is tested in the crucible of experimental science and found worthless—the task of keeping even fairly abreast with the most valuable novelties which are gradually finding a place among official *v. e.* authoritatively recognised remedies, is almost hopeless to the busy practitioner of medicine, who is expected to prescribe them or the chemist who has to keep them in stock.

It is chiefly this difficulty which the volume before us is intended to meet. "In scope and design it is totally distinct from any other work (on *Materia Medica*); for it embraces not only a very full account of the uses of the drugs handed down by the North American Indians to the medical men in America, but it brings up the list of drugs and chemicals to a late date, at the same time furnishing sufficient information on each to enable a medical man to see at a glance its probable value in any case in which he may require to employ it, or at any rate to decide in his mind if it is worth further research."

The Index is a special feature in this volume; as every drug has its botanical, native and common names given to it and in many instances their French, German and Indian equivalents, and will be found equally useful to the chemist and student of medicine as to the botanist and dealer in drugs.

The book is the joint production of Dr. Leonard of Detroit, America, who presides, we suppose, over the medical portions of the book and Mr. T. Christy, the well-known author of "Commercial Plants and Drugs," whose name alone should be a guarantee of the excellence and accuracy of the botanical portion.

As far as we may judge from casual references to drugs both new and old, the book is fairly reliable and the information given quite up to the latest date. It would be unreasonable to expect it to contain every new remedy—the name of which is legion—but it has included within its 387 pages, we believe, nearly every principal drug in the three Pharmacopœias of Great Britain, the United States, and India and a great many others non-official which have stood the test of time.

Of our island plants referred to in the body of the work and in the appendix we notice the *Anacardium occidentale* (caju) figuring in an aspect that is new to us. It is here called the *Diabetes bark tree*, and is recommended for the non-saccharine form of diabetes. We are not aware that it has any great local reputation for this affection, though we believe it is often prescribed by *veduralas* as an astringent. Another plant which according to Thwaites is not uncommon in the South of the island (*Andropogonis paniculata*, Wall.)—and which Mr. Thomas Christy claims to have introduced into European practice, and which is identified by its specific appellation (given above) and its common Hindustani name "Kariyat or Creyat"—is surely none other than our well-known *Hin bin kohomba*, the true *Chiretta* of the bazaars, according to Balfour—in common use all over India as a febrifuge and tonic and a cheap substitute for cinchona in every hospital in the East. It has been known for ages, and is the principal ingredient in the "*Drogu amère*" so much esteemed in France, the plant having been introduced into Southern India, according to Ainslie, from the Isle of France and cultivated in Tinnevely, though it is found wild in Bengal, Ceylon, the Peninsula and Java. We are surprised that this plant which is official in the Indian Pharmacopœia should have been included among the new remedies as "introduced by T. Christy, v. l. s.," while no suspicion seems to have crossed his mind (notwithstanding the affinity of the Indian name *Kariyat* or *Creyat*, derived from the Sanskrit *Kairata* whence *Chiretta*) that it was one at least of the sources of the well-known *Chiretta* of the Indian bazaars, which he describes in its proper place in this book as obtained from the *Ophelia Chirata*.

Another Ceylon plant is the *Cassia alata*, the

winged cassia or ringworm shrub, which though not indigenous is now naturalized all over the island. It is a favorite with the Tamils for ringworm, the fresh leaves, brised and mixed with lime juice, being used for the purpose. Also as a remedy for various skin diseases, in poisoned bites, &c., and as a general tonic. This shrub with its gaudy yellow flowers may be found growing almost wild both in Colombo and upcountry and would be worth introducing more freely among the Tamil coolies who appreciate the value of *sini agati*.

Holarrhena or *Wrightia anti-dysenterica*, better known as *Tellicherry bark*, *inderjow seeds*—the *suddu-idda* of the Sinhalese—*veppalei* in Tamil—is reputed as a remedy in dysentery, but it has no special action in this disease like *ipeacacanha*, and is only a good astringent and tonic.

Hygrophila spinosa or *Asteracantha longifolia*, well-known locally by its Tamil name *nirnulli*, is far better deserving of a place in any Dictionary of *Materia Medica*. It is not only one of the best diaretics known to the *veduralas*, but is superior to any known in European practice for the treatment of cases of dropsy complicated with diarrhœa or dysentery.

Of medicinal plants used for lung diseases, bronchitis, asthma, &c., we are pleased to find *Justicia adatoda* mentioned (*adhatoda*), *Tylophora asthmatica* (*hinooja*), and *Euphorbia pilulifera*, or snake-weed (*bohoda-keeriyā*)—all common plants, much used in native practice, and of deservedly great repute.

Still another is the *Cissia Fistula* or purging cassia (*ehela-gos*), which, to judge from the villainous mutilations constantly practised on the few beautiful specimens which (thanks to the late Mr. W. Ferguson) exist in the Cinnamon Gardens, seems to be in great demand among the Goths and Vandals who infest our streets.

It would not be difficult to pick holes in a Dictionary which aims at being at once comprehensive and succinct, but when the book reaches a second edition we would advise the printers' devil to be more careful of his orthography and to avoid such blunders as *CARYUM*, *CARDIMOMUM*, *SULPHOROSUM*, &c., while reserving a little more space for such useful well-known remedies as Calcic Sulphide, Aristol, &c. Phenacetin is surely deserving of a more detailed notice than "one of the European patent medicines prepared as a substitute for antipyrin, antefehrin, &c., used as an antipyretic." As far back as 1887 its chemical composition was described by Messrs. Hinsberg and Kast in the *Pharm. Zeit.* Berlin, as an acetyl derivative from Carboic Acid having the formula $\text{NH}_2\text{C}_6\text{H}_4\text{OCH}_2\text{COH}_2$ —and its physiological effects are already as well known as those of antipyrin, &c.

But, trivial omissions of this kind apart, the Dictionary appears to us to really supply a much felt want, while its moderate cost (five shillings, in beautiful cloth binding), and its dainty appearance should recommend it still further to medical men and vendors of drugs equally.

RUSSIAN TEAS: THEIR IMPORTATION INTO EUROPE.

A CRITIQUE ON THEIR QUALITIES, SPECIALTIES, ETC. (Specially contributed to the *Ceylon Observer*.)

A Russian engineer and traveller sojourning on the Riviera recently read an interesting paper before a select circle of listeners—both fair and firm—on the importation into, and distribution over, Europe of Russian teas, or, rather, of teas grown in China, and exported into Europe via Asiatic Russia by painful routes of immense distances, so vast and long that the journey, once undertaken, seems as though it will never end. There being no railways yet over the regions, everything is borne either by camels, sledges or canals—generally, all three methods of transit in succession. Nearly a year elapses ere the apparent "destination without end" of unknown fatigue and weariness is gained; before the historic frontier stone is reached, where on one side is chiefted ASIA and on the other side EUROPE; and ere finally the railroad at Nijni-Novgorod is come up to.

A partial translation will now be given of the leading features in this practical and instructive essay; and the faithful rendering into English will even preserve some of the peculiarities of expression of the original.

The teas of Russia, of which we occupy ourselves more especially in this study, are nothing else than the best crude teas of China. They are, in some sort, for the teas in general, what the Châteaux-Laffite or the Châteaux-Yquem brands are for the wines of France.

The plantations are, since nearly two centuries, engrossed or monopolised by the Russians or by their correspondents on the Chinese markets, and particularly at Hangkow, which is their veritable quarter-general. The Russian merchants at Moscow (the chief tea-dépôt of the European east) have numerous buyers in China, on the same spots of production, and cause their different teas to come by caravan.

The convoys which are formed at Tientsin are sent in a northerly direction, after which the camels transport these merchandises across the great and grand desert of Gobi, arrived at Mat-Ma-Tchin and then at Kiachta, ville située on the Siberian frontier.

It is in this neighbourhood that are centralised equally the teas of the septentrional provinces of China, which the inhabitants exchange for Russian merchandises and some manufactured objects. It is at Kiachta also that are found established the premier bureaux of sale and of re-expedition of the principal Russian Houses, who control carefully the merchandise, take the quantity necessary to the needs of the country, then put the cases in an envelope of cowskin of which the hair is turned to the interior, and send them to Irkontsk.

In this latter ville exists a new tea exchange, or comptoir, which takes the provision necessary for the commerce in tea of this country, and then causes to follow or forward the gross-bulk of the cargo train upon Tomsk and on Irbit.

Naturally, in this country, covered with snow pending the major part of the year, the sledges, chariots, and horses have replaced the camels.

It is at Irbit where each year has placed the grandest Asiatic fair, when myriads of nationalities flock together to do business, and when an important sale of teas is made; after which the convoys traverse the Ural gaining the Volga, in leaving a certain number of bales in each ville encountered on their route.

Once arrived at Nijni-Novgorod by the way of the grand river, the cases, of which the number is now much diminished, pass into the railway waggons, which conduct them to Moscow, from whence they are repacked or distributed in all parts of the nightless state of Russia, as well as to abroad.

The caravans, of which we have come to indicate the itinerary, part from Hangkow in the month of May, arriving at Irbit (in the Asiatic part of the Government of Perm) about the middle of February of the year following, and, after having mounted in sledges the congealed course of the Volga, they attain Nijni-Novgorod in March, and Moscow in April.

That makes 11 months of voyage to traverse China, Sighia, and the orient of Russia.

Russian tea is an excellent tonic and nutritive drink. These two qualities are due in part to two elements: the theine and the tannin. More the tea contains the theine, more it will be of value; further, — a detail to note, — is that the teas are more nutritive than coffee, because it is always more rich in theine than coffee is in caffeine.

Other than its native superiority, that which has made the Russian tea what it is and will be always — the best of all the teas — is this: that, coming by land and not being exposed to the atmosphere humid and warm of the holds of ships, it has no need to undergo the preparations indispensable to all teas coming by sea.

Among the different varieties of tea the most liked by the amateurs, we must cite, in the black teas, for example the Ki-Chin; in the flower-teas, the Si-o-Faioum; in the green teas, the Van-Kedzi; and in the yellow teas, the Ven-Ki and the Ta-tchou.

There may be signalised as a great speciality of the leading Russian houses, the tea in tablettes (a brevetted system). This is a product of excellent quality, compressed in a fashion guard concentrated all its force and all its aroma under the most petty volume possible. The voyagers, the chasers or sportsmen, the soldiers of all conditions appreciate it much in Russia, where they have named these tablettes "plitochni".

One must not confound these "plitochni" with the tea in bricks, of inferior quality named "kirplechni," of which use is made by the Kalmoucks, the Tartars, and the classes the most poor of the Siberian populations.

The tea in tablettes, which is broken in several morsels, is cast into boiling water the same as when making tea by infusing the leaves. A tablette suffices for making at least 120 cups of tea quite strong enough. It is prepared very rapidly, and possesses the same aroma and the same hygienic qualities as the different species which we have just cited higher up.

In resumen, owing to the powerful organization of this enterprise, we believe that the Russian teas, of which the price is not much superior to that for Chinese teas properly styled, or of the English teas, have their place marked in all the families of continental Europe, and in all the establishments of consumption cafés, hotels, restaurants, where, in becoming a favorite drink, they take range among the most precious auxiliaries of the public health.

Of course, everybody to their tastes: many persons of judgment there are who do not care for Russian teas.

We know, among our friends, some resolute amateurs of tea, a petty number of adversaries more or less undecided, recognising themselves incapable, after some contradictory experiences, of declaring for or against the famous infusion adored by the Chinese, the Russians, and the English.

This is, according to us, exclusively due to the multiple frauds of which tea is the object, that one has to attribute the hesitations of the public to pronounce in favour of certain infusions more or less faded and disagreeable, which he is made, to take or has passed off on him for some Chinese tea or Russian tea.

Such is the veritable cause which, unto now, has prevented in France the consumption on an extensive scale of these different products.

The subject is of interest not only to the general public, but also to business people. Some practical and edifying information has been given, such as seldom the community is made acquainted with. L. A.

OUR PORTRAITS.

MR. CHARLES ARTHUR TURTON.

We are always glad to be able to add to the list of portraits which have already appeared in this journal any that are of persons who have claims to public notice, and this we think the subject of our portrait this week, Mr. C. A. Turton, has, in that he is the inventor of one of the most useful inventions relating to tea manufacture that has perhaps ever been before the public.

Mr. Turton is the son of the late Rev. Henry Turton, M.A., of Suggall Hall, Staffordsire, Vicar of Betley in the same county, and was born on the 8th of January 1847. He was educated at Bradford College, Berkshire, and on leaving school he went to a private tutor as he was intended for the Home Civil Service for which he had a nomination. This however he threw up and closted to go into business in Liverpool. He remained in Liverpool during a continuous period of seven years in the service of one of the largest mercantile houses in that city. During the depression in the cotton trade in the year 1870, brought about chiefly by the Franco-Prussian war, Mr. Turton suffered some pecuniary losses, and seeing little prospect of obtaining a partnership in any good firm in Liverpool, he elected to emigrate to the Shining East, and selected Assam as the field for his future operations.

Being offered an appointment in the service of the Assam Company he left England to take up his new duties. He remained with the Assam Company for five years and left them to take over the management of the Sukwah Tea Company, in which capacity he acted for a period of 14 years, and of which company he is at present a considerable shareholder. He has now resigned the appointment under this company, and is engaged in pushing the invention of which we have made a cursory mention above.

This invention, a tea leaf withering machine, which he has named the "Cyclone," like many other inventions, has taken years to bring to anything like a state of perfection. He had not the opportunities that many inventors have of having all their time to devote to their one object, and of having workshops to experiment in; but he had to find out step by step the faults and failings of his system, and, as he says himself, but for the assistance of a neighboring planter, who took an interest in the machine from the first and who introduced it into his company, he doubts whether the invention would ever have attracted the attention it has now. From all we can hear of this invention, and judging from the highly satisfactory testimonials we have had an opportunity of reading regarding the work performed by the inventor's latest improved machines, we have little doubt that it has a great future before it. We do not purpose entering into a detailed description of the machine, but from what we can gather the inventor has produced one that will practically do away with large withering houses. It aims not only at economy of space but economy in labor, as the largest machines can be worked by half a dozen boys. The machine itself is of the most simple description, there being no complicated parts or machinery about it to get out of order, or that a factory carpenter could not put right at the shortest notice. It performs its work thoroughly in all weathers or conditions of atmosphere, preventing night work, and every planter knows what that means. It also produces the leaf withered to any extent desired with such perfect regularity as to keep the Tea Rollers and other machinery, &c., steadily at work from early morning until the whole of the leaf has been worked off. Perhaps the most surprising thing to learn about it is, that leaf which has been plucked off the trees a few minutes before the gong strikes at noon, and brought into the factory, often dripping wet, is passed through the machine within two hours and carried off to the rolling tables perfectly withered. This to practical planters might at first produce the impression that the leaf would suffer by such rapid withering, and that it must be necessary to wither it at a high temperature; but such we are assured is not the case, as by means of the new system adopted, the leaf is taken out of the machines quite cold, and, as those who have had opportunities of testing these new machines declare, "Withered to perfection." That the "Cyclone" witherer has at last begun to attract attention is proved by the fact that a considerable number of orders have lately been received for Assam and Cachar; one company alone will have six of them at work this season.

We hope to see the machines more widely patronized than they are already, as an invention of this kind, reducing the expense of labour and performing its work in a manner far superior to any of the other methods commonly in use, deserves to have given to it a prominent position in public favor.

Before closing these notes we might add that Mr. Norton in his younger days was a bit of a cricketer. His best year was in 1869 when he distinguished himself at Birkenhead Park against the All England eleven, receiving a presentation hat for his performance against them. He also kept up his interest in cricket whilst in Assam and captained the Nazira Team for many years in many a hard fought contest against their Jorehat and Dibrughur opponents. He was also an enthusiastic Volunteer. He began in his youth by serving as a private in the Dorsetshire Administrative Battalion, then as Lieutenant and Captain in the 4th Lancashire Artillery Volunteers, and finally as Captain of "A Troop," Sibsagar Mounted

Rifles, which corps he was chiefly instrumental in raising, and which has since increased so materially both in number and efficiency under its late popular commander Lieutenant-Colonel Buckingham, C.I.E., who had to resign this command to be promoted to the higher command of the Assam Valley Administrative Battalion.—*Indian Planter's Gazette*, Feb. 20.

POPPY TEA.

The reclaimed land grows the most splendid and abundant crops of corn. I have walked between two stacks, each 100 ft. long. But the land that grows corn grows also weed rankly; the drills are made nine inches apart, and gangs of women are employed with hoes to weed between the drills, two or three times in the year. With them goes a ganger to keep them to their work and prevent chattering. Time was when the ganger was armed with a sharp goad, with which he prodded the hoer between the shoulder blades. The demand for female labour has this disastrous effect—it draws the mothers away from their children. One thing may be seen in the Fens that is not pleasant, and that is the little plot of white poppy grown in the cottage garden. That plot means a good deal of evil. It means the making of "poppy tea"—in another word, opium to be administered to the babes while the mother is out at work. The little child is given its poppy tea in the morning, and the mother locks the cottage door, knowing the babe will sleep like a log till she returns at sunset. Children thus drugged have a dazed look through life, and have not their wits properly. They are heavy, with only flashes of intelligence. But it has another evil effect. It induces a craving for opium. The chemists could tell a tale that would cause surprise, if they chose, at the amount sold by them to the fen folk on market days. There is a little shyness about asking blankly for opium, and the received formula is: "I'll trouble you, sir, for an ounce of *that*." The chemist knows well what *that* means.—*Daily Graphic*, Feb. 15th

INDIAN TEA AT CHICAGO.

At a meeting of the Indian Tea Districts Association held this week, a proposal received from the directors of the recently-formed Palais Indian Tea Houses, Limited (Paris), for undertaking the work of exhibiting Indian tea in an appropriate way at the forthcoming Chicago Exhibition was considered. It was explained to the meeting that prodigious efforts were being made by Ceylon planters, assisted by liberal grants both from the Ceylon Government, the planters themselves and the commercial houses in Colombo, to have a thoroughly representative exhibition of their tea and a strong propaganda of its merits throughout the United States generally. It was felt that, although the work done by Ceylon would eventually help Indian tea also, it was hardly compatible with the dignity of the Indian planters to leave the work altogether to their neighbours, and that India also should be represented and the interests of Indian tea planters promoted. To work on the lines of the Ceylon planters would imply a larger disbursement of money than it seemed likely could readily be obtained. The case might be met, however, by accepting the proposals of the "Palais Indou" Company—a company which, it was well known, had been got up and subscribed for almost entirely of the chief London representatives of the tea companies and estates, but the small capital of which had been entirely absorbed by the work of introducing tea into France.

The proposal of this Company was that the tea planting community in Calcutta should raise a guarantee fund of, say, £3,000 or £4,000, endeavouring, if possible, to get the Indian or Bengal Govern-

ments to contribute some portion, and that, if that minimum sum were found, that the company would take any further risk upon their own shoulders, giving the benefit of their staff and organisation free of charge. A draft plan of the detailed proposal, with a diagram showing the proposed Indian palace for Chicago, designed by Mr. Purdon Clarke, together with a form of guarantee, were unanimously adopted by the meeting for distribution both among planters here, who had not already given their support to the Palais Company, and also among planters and others in India. A resolution was also passed urging the Calcutta Association to use its utmost endeavour to obtain the requisite funds, to ensure the work being carried out, and that promptly.

The matter is a most important one, and our readers will not be tardy in helping to open up this large and important market for Indian produce.—*H. and C. Mail*

THE RICINUS, OR CASTOR-OIL PLANT.

The Ricinus, like the Croton, is named after an objectionable insect, owing to the resemblance the seeds are supposed to bear thereto. The insect in this case is the cottle-tick, or as it was called in older times, and probably is to this day in other countries, *kik*. The plant is also known as Palma Christi, though the origin of this name does not seem very clear. I find equal difficulty concerning the origin of the word castor, as applied to the well-known medicinal vegetable oil obtained from the plant, especially as this is the generic name of the beaver, and castoreum or castory is the name of the peculiar liquor found in the beaver's groin; to say nothing about gemini, the fiery meteor occasionally observed on a ship's rigging. Owing to the name Castor-oil Plant, the seeds are also sometimes called Castor Beans. Strange as it may appear, Latin writers named the plant *Ocurebita* and *Hedera*.

Gerardo gives some interesting particulars concerning the misnaming of the plant, which he says, "Whereof mention is made in the fourth chapter of Jonas, and sixth verse." And he proceeds to say,—"Saint Augustine recordeth in his Eptatle to St. Jerome where in effect he writeth thus:—That neme Kikajion is of small moment, yet so small a matter caused a great tumult in Africa. For on a time a certain Bishop having on occasion to interest of this, which is mentioned in the fourth chapter of Jonas (in a collation, or sermon, which he made in his cathedrol), said that this plant was called *Ocurebita*, a Gourd, because it increased unto so great a quantity in so short a space or else (saith he), it is called *Hedera*. Upon the novelty and untruth of this his doctrine, the people were greatly offended, and thereof suddenly arose a tumult and burly-burly; so that the Bishop was enforced to go to the Jews, to ask their judgment as touching the name of this plant. And when he had received of them the true name, he made his open recantation, and confessed his error, and was justly accused for a falsifier of the Holy Scriptures."

Gerarde, moreover, considered the Ricinus 'was indigenous in America, and goes so far as to name it *Ricinus americanus*, though it appears to be of African and Indian origin.

Before I leave this old author, I may add his advice concerning the value of the plant as an antidote to sciatica, which so many gardeners suffer. He says, in effect:—"The broth of the meat supped up wherein the seed hath been sodden is good for the gout, and for and against the pain in hips called sciatica."

Reverting to America, it is considered moles will not remain where Ricinus seeds are sown. If this be the case, to any practical extent, the fact may occasionally be turned to good account in gardens, when, as sometimes happens, these singular creatures periodically visit newly-planted Celery in the trenches, Onion, Carrot, and other small seeds when sown, amongst which they create great havoc, and with difficulty are caught, or kept away. The difficulty being greater during mild periods in summer, when their runs are deep below the surface, and trapping is next

to impossible. It would be well to drop a few seeds into such injurious runs should they occur, and thus test the statement folly.

Seeds are offered by all seedsmen and at reasonable prices, and apart from such considerations as the above, they are so easily germinated and grown, as to be adapted for amateur culture, whether to grow on in pots, or for planting in open borders for summer decoration of a "tropical" kind. A pot, with seeds, placed inside a sunny window with a square of glass over it, quickly gives pleasing results, and they germinate upon a shelf in the greenhouse, sown about April.—WILLIAM EARLEY.—*Gardeners' Chronicle*.

QUININE AS A MEDICINE AND AS A PROPHYLACTIC.

Messrs. C. F. Boehringer and Söhne write:—

Waldhof bei Mannheim, Feb. 20th.

QUININE.—Lecturing on the 'influenza' at the Verein für innere Medizin in Berlin, Professor Gerhardt recommended quinine at the beginning of the illness, it being easier digestible than the more recent antipyretics. His experience also shows that if with the cessation of the fever a plentiful expectoration manifests itself, terpinhydrate may be taken to great advantage.

QUININE AS PROPHYLACTIC.—Mr. Rhodes, the well-known Prime Minister of the Cape Colony, reports that during his journey to Mashonaland he took plenty of quinine in order to resist the malaria fever. Thanks to this, he and his party got through the wilds without any of them being laid up with fever, and although they felt feverish, they succeeded in keeping it at bay.

We already in Nov. 1889 called the attention of the public to the prophylactic properties of quinine, in a pamphlet giving the result of observations by Dr. Binz, Dr. Graeser, Dr. Buwalda, Dr. O. Schelling and Dr. Tschirch showing that quinine guards against, and effectually prevents, malaria fever, and that it *alone* possesses such priceless efficacy.

NOTES ON PRODUCE AND FINANCE.

THE ART OF ADULTERATION.—Tea has an advantage over coffee and cocoa in that it is sold pure, and not manipulated by the manufacturer. In the good old days John Chinaman was given to nefarious pursuits in regard to tea, but the Indian or Ceylon tea sold to the consumer is pure. It is not so with coffee and cocoa, nor is it likely to be, so long as the law is so lax as regards adulteration. Occasionally the offenders are caught. For instance, at Lambeth Police-court a few days since, a grocer was charged with selling cocoa containing 36 per cent of added sugar and 20 per cent of added starch. The sanitary inspector proved purchasing the cocoa at the defendant's shop, and upon being subjected to analysis it was found to be adulterated to the extent maintained. The solicitor who appeared for the defence said his client had no intention of acting fraudulently, and had sold the cocoa in the same condition that he received it from the wholesale firm which supplied him. It was well known that there were many varieties of cocoa, and each of them had their own peculiarities, and the inspector must have known that pure cocoa could not be sold at 8d per lb. The grocer was fined, but no further reference was made to the manufacturer.

LAST WEEK'S SALES.—The market has been liberally supplied with Indian tea, says the *Produce Markets Review*, but the demand is innoctive except for the better kinds. Common sorts have been offered in an increasing proportion, the bulk being of exceptionally poor quality, for which there is but a moderate enquiry. The result of this is a drooping tendency in the prices for all common tea, which can only be checked by an increasing demand although there are no indications of this at the present moment. The better kinds, however, attract attention, and are readily bought at firm rates; and judging from the later arrivals, the stock of these grades is not likely

to prove in excess of requirements. It is, therefore probable that there will be a strong market for these descriptions for some time to come and the only check to an upward movement will be the large supplies of Ceylon tea, which will have a steadying effect should they prove to be of good quality. Although the sales of Ceylon teas, conformably with advices from the island, have been considerably smaller than last year up to the same date, the demand still continues inactive, and the slight recovery noticeable about the end of January in common teas has been lost. Finer teas, however, maintain their position well, although the demand is not very active even for those descriptions; but, as the quantity advertised for next week is small, present rates bid fair to be maintained. The quality has been fairly good, showing some improvement. Java teas have been much neglected.

WORTH NOTING.—Discussing last week's tea market, the *Grocer's Chronicle* says:—The course of the market this week has been listless and tending downwards for all but good liquoring teas. Fine and finest from either India or Ceylon command fullest attention and show no change in value; but common teas seem out of favour at the moment, and, probably owing to the slackness of the country demand, the dealers are unwilling to increase stocks. There is no doubt that the policy of tea planters this season has been mistaken, although, after the phenomenal rise witnessed last spring, when common leaf tea touched 10s., it is not surprising that producers should "go for" quantity in the following season. The wonder is that they did not allow their inclinations to lead them still further in the down grade. There is always a large proportion of low class tea at the end of every season, and this year, owing to the reasons just given, the proportion of common stuff is extraordinary. Low quality Ceylon is selling down to 4d and even 3½d. It would appear now that there are limits to the standard of quality, and no matter how temptingly low the price may be, the retailer must use the less of it when the quality goes too low rather than more; thus planters, by their desire to produce a very large quantity, are defeating their own object and damaging the prospects of the tea trade far more than they are aware of. Another feature this season has been the overwhelming quantity of inferior and low grade broken pekee. Ireland has always been the largest consumer of broken teas, and the native appreciation of good tea there is keener than anywhere else in the United Kingdom. But an over proportion of low grade tea, whilst fine and finest continue to fetch full prices and are scarce as well, disorganises the Irish trade in tea; and the serious fact is now seen that Broken Pekoes can be bought at 7½d with equal quality to whole leaf Pekoe at 9d.

BANANA FLOUR AND BANANA GROWING.—Mr. H. M. Stanley, the explorer, said several good words for banana flour in his ration books, but no steps have been taken to introduce it to the produce market. It is credited with being nutritious, palatable, and, above all, much more easy of digestion than wheat flour. Mr. Stanley claims that banana bread would be a good substitute for wheat bread as a standing article of human dietary. There seems no reason why it should not be so; that the flour will make bread, when properly dealt with, has been proved, we believe, by many practical experiments. The current issue of the *Kew Bulletin* states that the banana plantations of Fiji are threatened with ruin by a curious disease, or, rather, series of diseases. These consist of aphides, or plant-lice, a fungus causing rot in the root-stock, and various species of thread-worms. It is worth noting that in the soil about the roots of these plants nearly thirty different species of worms have been found, and of these about twenty-five are new to science, though as yet only two have been detected actually attacking the roots, living in certain brown, rotten cavities or between the sheaths of the leaves, and in some cases even at the very core where the tissues appear to be quite sound and white. The only suggestion for saving bananas as yet made is to plough up the land leaving it fallow, and

alternating some other crop. The ground could then be replanted with banana "stools" from an unaffected locality.

THE SILVER QUESTION.—According to the *New York Tribune*, although Mr. Foster, Secretary of the Treasury, is coming to England solely for personal reasons, he will confer with Mr. Goschen with a view to arranging an international conference to consider what action should be taken in regard to the silver question. So much the better. There cannot be a doubt that all parties in the United States are at present more anxious than ever to get the question settled. The Republican Party is committed to the Silver Act of last year; the Democratic Party is afraid that the free coinage movement may cause a split in its ranks on the eve of the elections. The British and the Indian Government must have viewed the recent decline in the Eastern exchanges and its possible consequences with concern. For nearly twenty years the question has been debated, and despite all the hopes of the optimists, it has not "settled itself," but has assumed a more acute form. It is believed that the Indian Government dare not borrow gold for railway extension, and a silver loan at the present time is out of the question. Something will have to be done.—*H. & C. Mail*, Feb. 26th.

"SIROCCO" ENGINEERING WORKS.

The extensive works belonging to Mr. S. O. Davidson, at Bridge End, Belfast, were recently the scene of an event of an extremely interesting character illustrating, as it did, the harmonious relations existing between Mr. Davidson and his employes. The occasion was the opening of the new dining and reading rooms which have been recently added to the works, and Mr. S. O. Davidson and Mrs. Davidson hospitably entertained the employes and their friends (numbering over 300) in connection with the ceremony. The new building, which is intended for the purposes mentioned, has been fitted up without regard to expense or trouble, the sole object of Mr. Davidson being the comfort and convenience of the people employed in the works. The principal portion of the proceedings took place in the lecture-hall, which occupies the third storey of the building. After tea, Mr. Davidson took the chair amidst applause, and briefly explained the object of the meeting. He said the special feature of their entertainment was to inaugurate the opening of these dining and reading rooms, which, in the first place, as they all knew, he intended for the daily convenience and accommodation of those employed in the works, and further to enable them occasionally to hold social gatherings, or for the purposes of educational lectures, without having to go to any place outside the Sirocco works. He considered that he could not have a more suitable test of the capacity and accommodation of the rooms than to employ them on the first occasion of their being used to meet there, as his guests and friends that evening, everyone who was in his employment along with a few of their own and his own personal friends. He sincerely hoped that this test would not discover many defects in the arrangements of the place, either as regarded the accommodation of the tea-rooms or that hall, as concert-room or hall-room. He offered them his hearty welcome that evening, and trusted that they would all enjoy themselves as thoroughly as he wished. On the motion of Mr. Hugh M'Bratney, seconded by Mr. William Frew, a vote of thanks was passed to Mr. Davidson for providing the dining and reading rooms. Mr. Davidson having replied, music, in which the Misses M. and K. Davidson took part, followed, and dancing went on until an early hour in the morning.—*H. & C. Mail*, Feb. 26th.

WATTLE CULTURE IN NATAL.—Before the Immigration Commission, a farmer related:—"He did not think the wattle industry would be overdone. He had started growing wattles fifteen years ago, and had found it answer. It was possible to clear £14 10s per acre.—*Natal Mercury*.

MEMORANDUM OF TERMS AND CONDITIONS OF SALE OF THE MILDURA IRRIGATION LANDS, VICTORIA.

Including Water-Rights, &c., under the Agreement entered into with the Government of the Colony, as authorised by Special Act of Parliament.

CASH PURCHASE SYSTEM.

Horticultural Lands.

1. The lands suitable for vineyards and fruit farms are divided into 10-acre allotments and sold at the cash price of £21 per acre to the maximum of 80 acres to any single purchaser:—£2 per acre of the purchase-money payable on application and the balance at the time of transfer. If cash be paid in full within one month from the date of application a discount of 2½ per cent. is allowed on the full amount. The above price includes water-right and one fully paid-up share in the Mildura Irrigation Company Limited for each acre of land purchased, as set forth below in paragraphs 7, 8, and 9.

N.B.—All the Pumping Machinery, Irrigation Channels, Conduits, and Pipes are constructed and provided at the cost of Chaffey Bros., Limited, for the conveyance of water to the highest corner for distribution in each allotment.

TIME PAYMENT SYSTEM.

2. Land for fruit cultivation may be purchased on *time payment*, subject to the same stipulations and conditions including water-rights, together with the same proportionate share in the Mildura Irrigation Company Limited, as above stated, upon the following conditions:—A deposit of £2 per acre is required upon application, and the balance of the purchase-money is paid upon the Building Society principle by monthly instalments extending over a term of five years. If desired, 10 years' terms may be arranged.

For each 10-acre horticultural allotment the purchaser will pay £20 deposit. Five years' interest at the rate of 5 per cent. is added to the balance of purchase-money (£190), and the total is divided into 60 instalments of £3 19s. 2d. per month. Instalments on the 10 years' system, £2 7s. 6d. per month.

Town and Suburban Lands. (All sold pending completion new survey.)

3. The lands subdivided for building sites will be sold at £25 each lot (ordinary size, 33 ft. x 155 ft.); £5 deposit, balance in two years, payable by monthly instalments of 18s. 4d. each, which includes interest.

Villa lots of the area of 2½ acres, £100 each; £20 deposit, balance in 5 years, payable by monthly instalments of £1 13s. 4d. each, which includes interest.

If the whole of the purchase-money be paid in full within one month from the date of application a discount of 2½ per cent. on the full amount is allowed.

LEASEHOLD SYSTEM.

4. All Purchasers may rent irrigated lands (the supply of water being included in such rental) for general agricultural purposes for a term of years to be agreed upon, at the annual charge of one quarter of the gross produce, and they may by special arrangement secure the power of purchasing such land within a given period.

TITLE CERTIFICATE.

5. *Title Certificates will be issued for all lands purchased whether upon the cash or time payment systems; and where the latter is preferred the purchaser will be required to execute the Company's form of mortgage (Registration Fee ten shillings). By this method the purchaser will have a negotiable security, and be placed*

in a better position to finance for the improvement of his land or otherwise, should he require it.

By special arrangement the Company is in a position to obtain for purchasers their Title Certificates at the reduced cost of £2 2s. for one or more lots not exceeding in aggregate value £50, with an additional 5s. stamp duty for every additional £50 value of land to be conveyed.

The Maintenance, Management, &c., of the Irrigation Works.

6. Every purchaser of land, whether for cash or on time payment, will have issued to him one *fully paid-up share* in the Mildura Irrigation Company Limited for each acre held by him. Each share will entitle the holder to one vote in the control of the management of the Irrigation Works; and each share will be issued as appurtenant to, transferred with, and inseparable from each acre of land.

7. The Irrigation Works will be under the control of a Board of Directors, who will be from time to time elected by the shareholders.

8. Each landholder will be called upon to sign the Company's agreement in respect of the water-rights and to pay a yearly charge (to be levied by the authority of the Mildura Irrigation Company Limited) at an equitable rate per acre sufficient to defray the working expenses of the irrigation machinery and works, and maintaining the same in good order and condition, *but there is no charge for interest upon cost of Pumping Machinery and Irrigation Works, which are all provided by Chaffey Bros. Limited.*

A printed copy of the Memorandum of the Articles of Association of the Mildura Irrigation Company Limited can be obtained on payment of One Shilling.

Further information if desired will be furnished on application to Chaffey Brothers Limited, Chaffey's Irrigation Offices, Swanston Street, Melbourne.

CULTIVATION OF LAND.

1st October, 1891. Cultivation is not compulsory. Land holders desiring to cultivate may improve either the whole or only a portion of their holdings, and the area under cultivation may be gradually increased to suit the convenience of owners.

The Company is prepared to enter into contracts for clearing, fencing, ploughing, grading, and planting allotments; also for tending same for one or more years. A large proportion of land holders, both non-resident and resident, have availed themselves of this system of cultivation, which affords special facilities for the acquisition of profitable fruit farms and vineyards by investors unable to take up immediate residence, or lacking the experience necessary to enable them to undertake the heavy initiatory work of preparation and planting.

In addition to the Company there are several private firms at Mildura and Renmark who undertake the work of preparation, planting, and tending for resident and non-resident owners.

The following estimate of expenditure is prepared with a view of showing the approximate amount of capital required for the purchase and cultivation of one 10-acre allotment, where the work of cultivation and tending is undertaken by the Company. The cost of plants varies from £1 for raisin-vine cuttings to £9 12s. for orange trees, per acre, and in order to arrive at an average the estimate provides for 5 acres each of vine cuttings and orange trees.

Prices of plants are subject to the usual fluctuations of the market. Quotations are given on application for orange, lemon, peach, apricot, nectarine, pear, fig, and prune trees; olive trun-

cheons; currant, raisin, and grape vine cuttings or rooted vines. It should be noted that whilst rooted vines cost about £6 per acre, *i.e.*, six times the cost of cuttings, the former give an earlier yield, and the growth is more certain.

The charges mentioned in the following estimate are necessarily approximate. Definite quotations will be supplied on application for the preparation and planting of specific allotments selected by purchasers.

ESTIMATED EXPENDITURE.

On one 10-acre Horticultural Allotment at Mildura purchased on the 5 years' Time Payment System, one half, *i.e.*, 5 acres, planted with Oranges, and the remainder with Raisin Vines, at the Company's Current Rates for Planting, Irrigating, and Cultivating Holdings for Resident or non-Resident Owners.

FIRST YEAR—	Rate.	£	s.	d.	£	s.	d.
Deposit on 10 Acres	2/-	20	0	0			
Twelve Monthly Installments, 5 years' system	3/19/2	47	10	0			
Title Charges			3	12	0		
Clearing 10 Acres (open country), say	10/-	5	0	0			
N.B.—If Timbered Land be selected, the Cost of Clearing will be from £1 10s. to £4 10s. per Acre.							
Cultivation.—First Year—							
Ploughing or Scarifying about 18 inches deep	1/5/-	12	10	0			
Clearing small roots and sticks, (stick picking) about	6/-	3	0	0			
Grading or Levelling, cost varies from 20s. to 60s. per acre, according to configuration of ground, say	2/-	20	0	0			
Planting, Cultivating, and Irrigating for 12 Months	7/-	70	0	0			
Water Rates.—About 6/- per acre per annum		3	0	0			
Plants.—5 Acres Oranges Raising	9/12/-	48	0	0			
Vine Cutting	1/-	5	0	0			
Fencing.—Cost of 1 End, 7 chains	15/-	5	5	0			
Half Cost of Division Fence, <i>viz.</i> , 2 sides and 1 end, 37 chains	7/6	13	17	6			
Gate		3	15	0			
TOTAL EXPENDITURE FIRST YEAR					260	9	

SECOND YEAR—	Rate.	£	s.	d.	£	s.	d.
Twelve Monthly Installments, five years' system	3/19/2	47	10	0			
Cultivation.—Cultivating and Irrigating	5/-	50	0	0			
Water Rates.—About 6/- per acre per annum		3	0	0			
TOTAL EXPENDITURE SECOND YEAR					100	10	0

Total Expenditure First Two Years, 5 years' system £360 19 6

10 years' system £322 19 6

The third year's outlay will also be £100 10s., after which the yield should be ample to cover all expenditure, including instalments on land.

1st October 1891.

BARK AND DRUG REPORT.

(From the Chemist and Druggist.)

LONDON, 18th Feb.

ANNATTO.—Eleven bags bright seed from Ceylon sold at 2d to 2½d per lb., and a large quantity of dull annatto seed realised from 1d to 2d.

NUX VOMICA.—Rather dull of sale, and somewhat easier. Sixty packages were shown, and the bulk of

this was bought in at 11s for slightly damaged fair grey seed from Colombo; some ordinary brownish seed from Coconada sold at 8s 9d per cwt.

QUININE.—Quite flat and easier. Second-hand German bulk is hawked about 9½d per oz. on the spot. At the Amsterdam bark sales in January last 17,865 kilos sulphate of quinine were offered, against 7,559 kilos in the January auction of 1891. In the February sale of this year 18,195 kilos were offered, against 9,312 kilos in February 1891. The total amount of quinine in the bark offered in Amsterdam during the first two months of this year exceeds considerably the total offerings during the first four months of 1891.

London, Feb. 24.

CINCHONA.—Tuesday's auctions were unusually heavy. The catalogues numbered of—

	Packages	Packages
Ceylon	978	of which	861	were sold
East Indian	1,447	do	1,346	do
South American	406	do	208	do
Java	173	do	173	do
African (West Coast)	563	do	563	do
Total	3,567	do	3,151	do

The greater part of the 413 packages which remained unsold at the auctions have subsequently been disposed of at the equivalent of the sale value. The large preponderance of Indian barks at the sales was again a somewhat prominent feature—India make, in fact, be said to have ousted Ceylon from the leading position she has of late years occupied upon our market. The supply of West African bark, too, was larger than we believe it has ever been before.

The following are the approximate quantities bought by the principal buyers:—

Agents for the Brunswick works	Lb.
Agents for the Mannheim and Amsterdam works	181,875
Agents for the Auerbach works	168,080
Messrs. Howard & Sons	82,794
Agents for the Italian and American works	69,518
Agents for the Frankfurt o/M and Stuttgart works	67,993
Sundry druggists	63,411
		60,422

Total quantity of bark sold 693,893
Bought in 165,004

Total quantity of bark offered 798,397
The auctions showed rather irregular results, but, considering the large quantity of bark offered, they proceeded very steadily. At first there was some improvement noticeable, but that was afterwards lost. The unit remains steady at 1½d per lb on an average. Much of the cinchona offered was of good quality, and there was a much larger percentage of Ledger bark than usual. The following figures represent the exports from Java during the second halves of the last five years:—

1891	1890	1889	1888	1887
Amster- dam lb.	Amster- dam lb.	Amster- dam lb.	Amster- dam lb.	Amster- dam lb.

Private plantations	4,693,747	3,851,391	2,221,745	1,874,188	1,635,729
Government plantations	459,823	270,318	292,915	335,433	381,477

Total 5,153,570 4,121,699 2,514,660 2,190,321 2,017,206
Feb. 25.

ESSENTIAL OILS.—Lemongrass flat at 19-16ths d. per oz. on the spot. To arrive there offers at 1½d c.i.f. Citronella offers on the spot at 1d per oz. in bottles and ¾d per oz. in tins. The c.i.f. quotation for tins is 10½d per lb.

JAVA TEA.—Last year was not a very good one for Java tea, the prices being low and the crop a small one. Towards the end of the year higher prices were obtained in Amsterdam than in London but it is a question whether this would have been so had the whole crop been put on the Amsterdam market. The attempt to get the tea direct to the consumers in Holland has met with so much success that further efforts are being made in that direction. In future Java tea will be exclusively used in the Netherlands Indian Army, and the Chinese, with an eye to business, have succeeded in getting hold of some tea plantations, which is deplored because the Chinese find ways and means of marking a profit which others would unwillingly resort to.—S. F. Press, March 8.

NOTES ON PRODUCE AND FINANCE.

THE PRODUCE CLEARING HOUSE.—Elsewhere we give a report of the proceedings held at the annual general meeting of the London Produce Clearing House. This organisation has become a very important factor in Mincing Lane, and one which it is impossible for the most conservative of the fraternity in the Lane to ignore. The fact that as large a quantity as 112,000 chests of Indian "type" tea passed through the books of the company during the year is remarkable, while in the report special reference is made to the increased dealings in Indian tea. A more important matter, however, is that the operations in this "future market" are likely in course of time to exercise considerable influence on the actual market on the spot for Indian teas, and it will be for producers to consider in what way they can, in their own interests, best utilise the organisation. To show that it might not be altogether without its uses let us only imagine that last spring, when prices for Souehong were pence per lb. over what they now are, that some producers had seen fit to sell their product of that grade forward, under the Clearing House contracts, and an easy calculation will show to what extent they might have gained thereby. Whether, however, planters use or do not use this organisation, there is no doubt, as already mentioned, that the dealers through this company will have widely-extending influences upon the market. It is a sign of the times to find conservative Mincing Lane at last waking up to new methods of doing business, long familiar to our neighbours beyond the sea.

LAST WEEK'S TEA SALES.—The supply of Indian tea brought forward still consists principally of common grades of much inferior quality to those offered a few weeks ago (says the *Produce Markets' Review*), while prices have been irregular, and occasionally lower, for the less desirable parcels. Unless there is a much stronger demand for these grades, current rates can hardly be maintained, notwithstanding their present low prices. On the other hand, teas of good useful quality are scarce, and are eagerly sought after at higher prices. This has been particularly noticeable in the past week's public sales, more especially for whole-leaf kinds, which showed considerable advance from the lowest point. Broken Pokoes have shared in the upward movement, but to a smaller extent, while the finest grades continue to be actively competed for at prices showing a further rise. The enquiry, in fact, during the past season has been for tea with quality, which proves that the demand more for price is declining. Importers would do well to note this, and instead of flooding the market with tea of undesirable character, they should turn their attention to procuring a larger proportion of good medium and fine descriptions, in doing which their interests would undoubtedly be better served. If, however, they persist in the present course, which will largely augment the supply in the coming season, coupled with a probable import of nearly 80,000,000 lb. from Ceylon, they must be prepared to face the lowest prices yet recorded. At the public sales 32,623 packages were brought forward, and the bidding was brisk for all good grades, but the common sorts were comparatively neglected. The Ceylon sales, in accordance with the reports from Ceylon as to the quantity exported, have again been rather smaller than was generally anticipated by the home trade, and prices have been full maintained, and in most cases have exceeded the January quotations. The quality has been fairly good, but perfect excellence in this respect is hardly to be expected until rather later on in the season. Strong efforts are evidently to be made not only by merchants and dealers, but also by representatives sent direct from the island, to push Ceylon teas at the forthcoming Chicago Exhibition; and when the success which attended the efforts made at the late Colonial Exhibition to bring Ceylon teas into general favour is considered, it is hardly to be doubted that a great stride will also be made by these means in the United States. This question, although not of immediate importance, must ultimately

have a strong bearing upon the future price of tea in general.

THE EXCHANGE BUGBEAR.—The silver problem and the ups and downs, chiefly downs, in the rates of exchange between this country and the Far East have become too burdensome. It is no wonder, therefore, that in India business men are becoming restive on the subject. The position of a business man in India is a trying one. A decline in exchange tends in the first instance to stimulate the buyer of imported goods, because he feels that with every fall in the gold equivalent of rupee prices there is the less probability of his being able to buy later on at lower rupee prices; in other words, he is the more disposed to think that prices in the silver currency, with which he alone has to do, have in commercial parlance, "touched bottom." But the very fact of a decline which is purely arbitrary, as it is due to conditions absolutely outside the circumstances of the trade in which he is engaged, and is quite incalculable, makes him doubtful as to whether a reverse movement may not ensue, and mark his purchases relatively dear. No wonder, then, that the fall in exchanges has become the chief topic in business circles in India, for, with either a falling tendency of exchange such as has been now practically continuous since October, 1890, or a rising tendency of exchange such as was experienced from May, 1889, to September, 1890, the importer and exporter alike are equally uncertain how to act. However accurate may be their calculations, of demand and supply in regard to the commodities in which they deal, however shrewd their forecasts of the seasons, they are still as likely to find their operations end in loss as if they were mere gamblers.

A SUPPOSED RIG.—There is talk of a French rig in office. Its home is in Havre, Neither New York, London, nor Hamburg is implicated in the business, but Antwerp is said to have an interest in it.—*H. and C. Mail*, Feb. 19.

AN EX-CEYLON PLANTER IN AUSTRALIA.

LIFE OF A "JACKAROO"—PADDOCKS AND SHEEP-RUNS—IN THE INTERIOR—MILDURA—SUNDAY OBSERVANCE—A DAY AND A HALF OF WORK.

Feb. 16th.

I have several items to write about, and will likely enclose papers which you may be pleased to publish. I am here living on a station in N. S. Wales. The life of a "jackaroo" or gentleman apprentice, or what you call in Ceylon a "creeper," is a pleasant mixture of pleasure and pain, of rough jobs and glorious riding over the flat grass paddocks. A "paddock" is a field, but a very large field. Some are 2,000 acres others are 8,000 acres. Sheep-runs go from 30,000 acres to 300,000 acres, and the grazing power of the land is very finely adjusted since universal fencing took the place of sheparding in days gone by. Mobs are placed in paddocks, and the number of sheep per acre, or the number of acres per sheep, is nicely arranged. The breeding and selecting is so easily managed in paddocks, and fewer men are necessary. Formerly shepherds lost their sheep like little Bo-peep and didn't know where to find them. Rams and cows and lambs were all mixed up; and what was worse, neighbours found their sheep getting mixed. Now everything is orderly and methodical. I am not, as you will be sure, capable of explaining the management of a sheep-run after a week's experience, but a short sketchy description of the scenes and scenery might interest your readers.

After finding that Melbourne did not exactly welcome me, in fact the times were so hard that new comers seeking employment were not likely to be welcomed when those already on the spot were finding it a difficult thing to live, I journeyed into "the interior," as a Ceylon conductor would say, and found myself across the Murray, my old friend at Mildura, and speeding across New South Wales, across a flat, hot, dry, plain. I arrived at Deniliquin and eventually found the station which was

my destination. *The sloping garden* where "Paddy," not the Irishman, but the *Chinaman*, tells in endless and untiring industry—watering, watering, watering in this thirsty climate. His water-melons and lock-melons are delicious in this climate. Why cannot melons be cultivated in Ceylon? Surely in Jaffna large quantities could be grown.* *The house*, where blinds keep out the light and fine wire gauze doors keep out the flies, and glass doors and windows keep out the hot winds when they blow. The house is comfortable, nay, luxuriously furnished and grape vines and creepers shade the verandahs. The kitchens and other rooms form a wing at right angles, and round the back are the store, the men's quarters, the various sheds and stables and yards form what you in Ceylon call a "compound." Then farther on is the cottage of an old pensioner "Harry," and beyond that the stock yard where horses and cattle are driven into and out of constantly. About half a mile away is the wool-shed and sheep yards, and then away to the far horizon—where deceitful mirages pretend that the distant timber is dipping in cool waters—stretches the flat succession of paddocks all fenced with wire and posts. Ah that mirage! In old days how much the tortured wanderer, lost—bushed—for days, felt the anguish of Tantalus as his eyes revealed cool lakes into which the gums and boxtrees dipped their tassels. Near this are the "Old Man Plains" a great stretch of dry plain across which many failed to make their way to the Murray and lay down and died in days gone by. Near by, say half a mile, is the township—two hotels and a hovel or two, where drink breeds a curse to the improvident station hand, where the jaded coach-travellers staken their thirst while they are changing horses. These hotels, pubs, or shanties, are a greater curse rather than a convenience. Away beyond the township stretches the "common," a reserve attached to every township for special grazing privileges, a treeless plain as far as the eye can reach save the faint edging of timber barely visible in the horizon. Sometimes the soil is red and hard, sometimes it is light-colored and sandy, sometimes it is dark and covered over with deep cracks showing the stiff clayeyness of its composition. The last mentioned is *heavy* feeding, the second is *light* feeding, the first is *sweet* feeding. The first mentioned is the best in Mildura. Let us mount the well-trained station-horse "Jimmy" and start with our host round the yard and away past the wool shed and out into the paddocks. Great mobs of sheep will stare at us as we "amble" along; or, alarmed at the sight of the colley, they will move rapidly away in a long gray line marked by dust to another "camp" in the paddock. Every paddock is so defined that sufficient water, and variety of feed is well distributed. The water is found on the "frontage" of the Billabong creek or in water-holes, or tanks or lagoons. As the water dries up there is great danger of the sheep getting "bogged" in the mud. As we drove along the other day my host jumped out of the buggy and had the disagreeable duty of dragging a bogged sheep out of the water-hole which had become, to put it mildly, considerably "high." And talking of driving—driving over the endless plains is not wonderful, but when you get on to a pine-ridge and go right through the bush among thickly growing pines in a double-horse buggy the sensation is decidedly novel. The perfect obedience of the horses and the skilful manipulation of the reins was worth seeing.†

I have taken part in moving a few fat bullocks into some other paddocks, and shifting some horses over the run, and this has been very enjoyable; but it is merely child's play compared to real cutting out cattle and horses, but still the whole thing is pleasant and enjoyable in its novelty. Sitting in the garden in the moon-light the dark pines dotted about on the park-like expanse, and the varied felage along

* In our time, half a century ago, water melons were largely cultivated, and we suppose they still are.—En. T. A.

† The navigation of road traces covered with mouse tree stumps is wonderful.—Ed. T. A.

the creek, and the white painted water-tank standing on tall scaffolding to which a steam engine pumps up water for garden and bathing purposes—all this form a delightful surrounding in the dry crisp coolness of the evening air. But I have not yet begun the real duties of a "jackaroo," and much of the glamour and novelty will soon be rubbed off in putting one's hand to a job whatever may offer, or to whatever one is ordered by the "boss." But still the climate, the food, the surroundings, are infinitely superior to the enervating, sensual, relaxing climate of Coeylen with the ever-present native at one's beck and call. Mildura is to be the heaçon that will beckon me on: for that I will save money, and that will, I hope, be my haven of rest after years of unsettled restlessness.

As I write, the stillness and quiet of Sunday is round the place. Even the Chinaman in the garden refrains from his singing: at least I suppose he means the sounds he utters sometimes to be the outpourings of a happy heart in the enjoyment of song. Sunday is a day of rest on a station just as on a plantation in Ceylon.

ABERDONENSIS.

T.S.—Since writing the above I have *put in* a day and a half of work with my hands, and they are swollen and tender and wounded. A capital thing in a country of the white man, dont-cher-know, to use one's hands a bit instead of these everlasting coelies, dont-chor-see? Fine thing to recommend to some other fellow, but it gets monotonous to say the least of it, especially in a "white man's country" and you have the horny-handed son of toil muttering in his beard about the "damned jackaroo." I strongly recommend discontented dories to "take a hand" in roadmaking or cutting wood or breaking stones for two days, and try to imagine it is *Australia!* These glorious gallops, you know, bounding and boundless prairies, fresh, crisp air, and ah!—ah very sore at the "feet of the back." Yeth-aw-dont-cher-know.

(Copy of Letter sent to the Editor of the "Brisbane Courier")

Dear Sir,—In the issue of the *Argus* of the 13th inst., there is a manifesto by Sir Samuel Griffith, favouring the introduction of Polynesian labour.

It begins by explaining how the change of opinion in his policy or in his attitude towards the question of coloured labour occurred. The chief reasons that had influenced his opinion, and had made him a determined opponent to the importation of coloured labour, are enumerated. I will go over them.

1. It tended to encourage the creation of large landed estates owned for the most part by absentees, and worked by gang-labour and so discouraged actual settlement by small farmers working for themselves.

2. It led to field labour, in tropical agriculture being looked down upon as degrading and unworthy of the white races.

3. The permanent existence of a large servile population amongst us, and not admitted to the franchise, is not compatible with the continuance of our free political institutions. And besides this is added, so far as Polynesian labour was concerned, the discredit that had been brought upon Queensland by the abuses in the South Sea Island Trade. I have been a planter in Ceylon and India for 18 years, and have worked Cinchese, Tamil, and Canarese coolies during that time; and I have thoroughly studied the question of coloured labour, how to get it, and how to keep it. I knew how labour is sent to Mauritius, the West Indies, the Cape, &c., from India, how they are safeguarded and protected by Government; and how they come back to India with great (comparative) wealth. The immense boon of a class of labourers, docile, industrious—from part of our own dominions, and protected by Government, being introduced into a country, tropical, or sub-tropical can only be realized by those who have worked coloured labour. In Ceylon we got Tamil Coolies from the South of India to come over and work in our plantations. The recruiting is closely watched, and many of our recruiting agents, or kanganyes, are incarcerated for breaking the simple precautionary rules

as regards minors. This prevents abuse, because unlike Mauritius, &c., the coolies are not protected by special Government regulations, but, being so near, they are supposed to come and go voluntarily. The kanganyes receive advances of money from the Ceylon planters, and they go over and recruit in the villages and collect gangs of coolies at about (roughly) a pound a head. But since coffee failed, and tea arose in its stead, there has been far too little recruiting in India. Coolies now-a-days prefer to remain in a country where they have more freedom and license, far from the restraining influences of caste, priests, and family ties, where money is more plentiful, and life more exciting and lively. The Tamil Coolie when he first lands in Ceylon suffers from a revulsion of feeling when he finds the *couleur-de-rose* promises of the kangany fade away into real life. But gradually he gets used to the new order of things and grows contented—even happy. Then there has grown up what I may call a "creole" class of coolie. What I mean by a creole class are those coolies born of Indian parents, but born and bred in Ceylon, who have not seen the country of their fathers, and who only know the country of their birth. These coolies form themselves into gangs and go from estate to estate trying to get larger advances, and they at last get so indebted to their kanganyes, that they are virtually enslaved to them. Planters have unfortunately been obliged to play into those kanganyes' hands and the rate of advances has gone up, and the security of a settled labour force has been shaken by those restless gangs who try to obtain higher advances. But, notwithstanding, those drawbacks, Ceylon stands in a unique position as regards facility of labour. In Southern India, of course, they obtain labour in the country itself, but one disadvantage arises from being too near the homes of the labourers for this renders the labourer too independent, because he is within "measurable distance" of his home, and can go and come—*malgré* the convenience or control of the planter. But in Ceylon, though the coolie is supposed to be a free agent, and is really so as regards the planter, yet is not so as regards his kangani, or proprietor of the gang; and in any case the existence of the sea being between him and his home, greatly strengthens the hands of the planter in Ceylon, as compared to Southern India. The labour is drawn from an immense country in Southern India, which is thickly populated with Tamil-speaking people. But there are other tracts where "Malayalam" and "Telugu" are spoken, and then Mysore, where Canarese is spoken, which would yield immense labour-gangs for our colonies.

Now I am coming gradually round to this question of Queensland requirements. The Cinchales are not very suitable for plantation work; though, since tea-cultivation has so greatly increased, very many Cinchales who have suffered from the coffee failure,—partly because they grew it, but chiefly because they stole it from plantations, and cannot now steal it since coffee plantations have been superseded by tea-gardens—very many Cinchales have begun to work, and giving great satisfaction. But the fact of their being so near their villages, like the case of the Indian coolie, renders them unreliable, unsettled, and independent.

Mr. St. George Caulfield did much to influence Queensland against Indian labourers by importing the scum of the Colombo Jail and "Sea Street" bullies. Many of those rascals were wrecked in the "Quetta" going home lately, and are giving trouble in the neighbourhood of the wreck. These Cinchales scoundrels gave Queensland an unfavourable impression of Indian labourers. But the unsophisticated Tamil, or, if you like, the sophisticated—this is a very different thing. The Hindustani or Bengali labourer is very largely sent to the West Indies under Government Protection. Now here is a vast field of available labour, and in Queensland you have a vast unopened tropical country, rich with undeveloped wealth, ready to grow products which this Southern Empire has to get from outside her bounds. Cotton, coffee, tea, chocolate, rice, maize, coconuts, tobacco, spices, &c., all those tropical riches are, as it were, latent in your soil and climate, and who bars the way? The dog-in-the-manger white labourer who cannot work

himself, and grudges his coloured brother a "show." The white man has all the rest of the country; but here a hard and fast line must be drawn as the white and black cannot work alongside each other. But before we go farther with the question of labour I must point out that "mining" must be prohibited where plantations are established because a rush of miners will ruin any tropical planter. I am new to this country, and am not very sure of my ground, but I understand that the Government reserves all right to minerals; and, should valuable minerals be discovered, miners are admitted to take up allotments or "claims." If that is allowed in Northern Queensland then capitalists could never be expected to open up the country in tropical agriculture, and would not dream of importing Indian labour.

My idea is, let there be full compensation made to planters in the event of a miners' rush; or let the planter benefit by the chance of minerals being found on his property, and protect him in the possession of it. Then Government could appoint immigration agents and commence negotiations with the Indian Government. The three causes that rendered Sir Samuel Griffith a determined opponent to coloured labour, seem to a tropical planter very weak, narrow and unworthy of a great politician. No wonder that his mind has at last shaken off the shackles, and has risen above such a narrow horizon. And now let us see what reasons have roused him. He finds that the sugarcane can be cultivated by white families and sold to the manufacturers at reasonable prices, yet there are not enough of Europeans to carry this out everywhere, and the planters are really in great straits for labour, and mills have therefore to be closed. Now the Government step in and tries to save an industry that it has done its best to strangle. Sir Samuel Griffith appears to favour Polynesian to Asiatic labour. I know nothing of Polynesian labour except what I have read and heard. Fiji's experience, and also the past experience of Queensland does not lead me into the belief that those scattered islands of the East, where kidnapping and reprisals in the shape of murders of boats' crews are the best recruiting grounds for Queensland. Turn to the other side. You approach an Empire, whose civilization is the oldest in the world, whose present Government is a model to the rest of Governments, whose teeming millions of industrious races are ready to go and work—not on the selfish principle of the heather Chinese,—an alien of the Empire—but as fellow-subjects of the Crown. They are docile, intelligent, and obedient. You have a glorious tropical country that has been strangled by the close proximity of the white labourer. Had there been a stretch of sea between Queensland and the rest of Australia, it would long ago have settled matters in accordance with the peculiar and special circumstances and position, regardless of the jealous and selfish hotings of her sister colonies.

(Signed) W. A. TYTLER.

THE AMSTERDAM CINCHONA AUCTIONS.

(Telegram from our Correspondent.)

AMSTERDAM, February 25th.

At today's cinchona auctions 4,780 packages of Java bark, representing about 510,000 oz. sulphate of quinine, were offered for sale. With fair competition, 4,067 packages sold at an average unit of 6½ cents. (equal to 1½d to 1¾d per lb.), being about equal to that obtained at Tuesday's London auctions, and the same as that at the Amsterdam auctions of January 21st. Considering the heavy quantity of bark offered, this is very satisfactory. The following prices were paid:—Manufacturing barks in chips, broken quill and long quill from 15 to 36 cents. (equal 2½d to 6½d per lb.); ditto root, 15 to 30 cents. (equal to 2½d to 5½d per lb.); druggists' barks, in chips, broken quill and long quill, from 6 to 60 cents. (equal to 1d to 10½d per lb.); ditto root from 16 to 54 cents. (equal to 2½d to 10d per lb.). The principal

pal buyers were Gustav Briegleb, of Amsterdam, the Bannswick quinine works, and the Mannheim and Amsterdam works. (Mr. Briegleb is supposed to buy for one of the American factories, one of the heads of which attended the sales. It is his purchases that gave rise to the "syndicate of buyers" report a few weeks ago.)—*Chemist and Druggist.*

SCOTTISH ASSAM TEA COMPANY, LIMITED.

The Secretary of the Company has issued the following to the shareholders:—"I have the pleasure to inform you that the total quantity of tea made during season 1891 has amounted to 376,608 lb., which, although 26,562 lb. less than the exceptionally large crop of the previous year, is still about 33,000 lb. in excess of the quantity made in 1889. Up to this date about 308,400 lb. of the season's teas have been sold, producing a gross sum of £13,044, being an average price of fully 10½d per lb., as against 11½d per lb. average realised for whole crop of the preceding year. Five invoices yet remain to be sold, and, taking these at or about Calcutta valuations, it is estimated that the total crop will produce a gross sum of about £15,750, as against £18,600 gross proceeds of crop 1890. Complete accounts have not yet been received from India, but from the figures already available it is evident that the expenditure for 1891 will considerably exceed that of the previous year, the excess arising chiefly under the heads of "additions to machinery" and "cost of importing and recruiting new coolies." On the other hand, there has been a substantial gain (about £1,500) under the head of "exchange," and the rate for remittance to India still continues exceptionally favourable. The latest accounts from the Gardens are of a satisfactory nature, all cold weather operations—such as hoeing, pruning, renewal of buildings, &c.—were well advanced, and everything was being got ready for making a vigorous start with the new season.—*H. and C. Mail, Feb. 26th.*

INCREASING THE LIFE OF WOODEN SLEEPERS.

From a paper read by Mr. H. W. Reed at the Ninth Annual Convention of the Road Masters' Association of America in August last, we learn that in the United States alone, more than 73 millions of wooden sleepers are used annually, and that the present timber areas cannot possibly continue to supply more than half that quantity. This has caused American railway engineers to devote more attention to the different methods by which timber can be preserved than has been the case in other countries, and Mr. Reed also points out that there are several methods of preserving the life of sleepers, besides the use of chemical preservatives.

1st. "By selecting the most durable timber, and insisting upon the use of properly designed bearing, or base, plates whenever soft wood sleepers are used." The average life of black cypress sleepers is eight years, and of red cedar, seven years, when the rails are allowed to rest directly on the sleepers; but when bearing plates are used, Mr. Reed estimates the life of the same sleepers at twelve years at least. When soft wood sleepers are used with double or bull-headed rails, their life may be increased from 50 to 75 per cent by using chairs with a very broad base; for as we have pointed out more than once, sleepers of this sort are, in the majority of cases, crushed or bent to pieces long before they are worn-out or decayed. Anyone who will take the trouble to examine the creosoted fir or cedar sleepers taken out of any Indian Railway, as unfit for further use, will find that at least 75 per cent are fairly sound with the exception of a small portion on either side of the rail or chair-seat. In connection with this, we may point out that the chairs in use on all the large railways in Great Britain, are from 35 to 100 per cent heavier than those in use on Indian Railways; and, consequently, they have a larger bearing surface, and do not damage the wood so much as smaller chairs.

2nd. "Give proper attention to the specification for, and inspection of, sleepers." Mr. Reed points out that although every Company has its own specifications, which require a certain width of heart, freedom from wind-shakes, rot, hollows, splits, &c., it is customary to allow slight variations from the specification, and that contractors will frequently take advantage of this variation unless the sleeper inspector exercises great firmness, and an unusual amount of good judgment. This is certainly a most important point, and it should always be distinctly stated in the agreement, what amount of variation is to be allowed, instead of leaving this to the discretion of the inspecting officer, as is too often the case. A difference of one or two inches in the length of a sleeper is not of much importance, but not more than half an inch difference in width should be allowed when broad gauge sleepers are being examined, and any that have large gum veins, hollows, or splits, should be rejected.

Thousands of wooden sleepers are condemned every year as being unfit to remain in the road, solely because they are split in the centre to such an extent that there is no hold for the spikes: when such sleepers were accepted, the cracks were no doubt very small and these could have been prevented from increasing in size by putting an half inch bolt through the sleeper about six or nine inches from the end: two plates or washers, four inches square, and one-fourth of an inch thick, would also be required, and the whole could be made of scrap-iron. Dog-nails, bands of hoop-iron, and the many other methods which have been tried, are of no practical value, but split sleepers when properly secured in the manner above described last as long as sound sleepers and are quite as valuable. Even sound sleepers often split after they have been in use for a short time, and as the cost of the bolt, and washers, including the labour of fixing, would not be more than one rupee per sleeper 'if done at both ends,' it would perhaps be a saving in the end if all wooden sleepers were so treated before being put into the road as a preventive measure.

The cost of maintenance is largely influenced by the life of the sleepers used, and if by securing the ends this can be increased by two years, it will certainly repay the cost of applying the bolts.

Any sleepers that have more than half an inch of sap-wood either in depth or breadth, should be rejected as unfit for main line use; such sleepers deteriorate very quickly, and often lose one-third of their original size within three or four years.

3rd. "Sleepers should not be cut when sap is flowing freely." From experiments made by Mr. Reed it was found that yellow pine sleepers cut during the months of January, February, and June (in South Georgia) had at least 20 per cent. longer life than sleepers cut during other months.

4th. "Sleepers should be properly seasoned before being used, and this can be best done by piling, so that a free circulation of air can be maintained through and around, them." Sngcocticoes Nos. 3 and 4 are certainly deserving of more attention than they have hitherto received in this country. As a rule, Indian contractors cut sleepers whenever labour is available, and this no doubt is the reason why sleepers of the same class, cut within a short distance of each other, give results so widely different. Wooden sleepers are often allowed to lie about in the forest for a month or two after being sawn, if there is not sufficient water in the nearest river to float them in; or, if the cart tracks (they cannot be called roads) are in bad order, but no regular procedure is followed; and all contractors try to deliver the whole of their stock as soon as possible after it is cut. When stacked at the depot they are usually laid so close together that only those on the outside of the pile get any fresh air, and when material is required for construction or renewals, sleepers are not allowed to remain at the depot longer than is actually necessary. To leave them exposed to the sun's rays would cause many to split, but cheap sheds with tiled or boarded roofs could be provided at a small cost, and it would then be possible to season them for a year or more, instead of using them within six months from the date on which the trees were cut down.

5th. "Proper drainage of the road-bed will increase the life of sleepers." In this respect Indian railways are far ahead of those in any other country. The advantages to be derived from the use of good stone ballast do not appear to be thoroughly understood even yet on European or American railways, although some of the best practical men in each country fully recognize its value, and have recommended its being adopted as the standard whenever practicable.

6th. "Proper care of sleeper." The practice of using picks to pull sleepers into place is destructive of their life, for the pick not only makes holes that admit water into the sleepers, but often splits the sleeper, thus providing an avenue for its rapid destruction. Hooks are much better than picks for placing sleepers. Old spike-holes are also a prolific cause of decay and should be plugged with wood when re-spike. The suggestions made in the last paragraph of Mr. Reed's paper are deserving of attention, and we believe that most railway men in this country are aware of the necessity of attending to such details.

Before leaving this subject we may mention that in America sawn sleepers are only used when hewn sleepers are not procurable. Mr. W. B. Parson, C.E., Engineer in charge of the United States Sub-way Company, who has had a large amount of experience with wooden sleepers, says: "Hewn sleepers are preferable because they are more durable; men of experience in such matters claim that the adze in hewing closes the pores of the wood, while the saw leaves them open to absorb moisture and hasten decay. A great objection to sawn sleepers is that they can be made from large coarse-grained sticks, giving several sleepers to a section, and it is even possible to presave old or dead timber when decayed portions have been removed by the saw."

In Australia also, sawn sleepers are not in favour and it is generally specified that the logs are to be split with wedges in the same manner as wooden fencing: this prevents cross-grain timber being used. Neither splitting or hewing appears to have been tried in India or Europe to any appreciable extent; and if sawn sleepers were objected to, a higher price would probably be demanded, as there would be a great deal of waste with large log if they were split instead of sawn.—*Indian Engineer.*

NOTES FROM YERCAUD.

(From our own Correspondent.)

YERCAUD, March 8.—Since my last letter the stream of arrivals has run steadily on and the Ho! Hum! Ya! Cum! song of the bearers is now a daily sound. It is impossible not to admire the good humour, and general cheeriness of these men who, in all weathers, often cold, hungry, and ill-clad, set willingly to their by no means easy task of breasting the ghaat with perhaps sixteen stone of solid weight upon their shoulders, and lighten their way with ceaseless quip, crank, and jest. The ease and economy with which the Shevnoys can be reached is remarkable, and if more widely known would certainly count much in their favour. Leaving Madras in the evening Scorammungalum, or Salem, the station for the Hills, is reached by 4 a.m. the next morning, giving time for a comfortable wash and brush up and *chota haari* before the dawn appears. A brougham, bullock coach, or the rapid, though less luxurious, jutka, covers the ground to the foot of the Hills in less than an hour, and the cheery bearers have horse their burdens aloft and left the hurning plains well behind before the power of the sun begins to make itself felt. Yercaud is reached easily by 9 o'clock, then a bath, breakfast, a siesta and lo! what a change is there. Can this bright, alert, cool looking individual be that gasping, dust-begrimed creature that was called a Madrassee yesterday? If so would that his fellow Madrassee could see him, and do likewise! Only fourteen short hours since he was driving to the Central Station amidst noise, dust, smells and blasts of hot wind, and wondering to himself whether life was worth

living. Now he has no hesitation in answering that question in the affirmative.

If this delightful exchange can be obtained by one night's travelling, then he is full of pity for the people who go further and perhaps fare worse. Rarely does a visitor who comes here for the first time go away disappointed, and numbers are filled with surprise and regret that the existence of so delightful and get-at-able a health resort had remained so long unknown to them. An occasional visitor from Bengal declares it to be far superior in every possible way to Darjeeling, and considers it worth the extra trouble and length of journey to get here. Epidemics are almost unknown, even the simple one of measles, which is constantly present in Ooty, never appearing. The belief that the Shevnoyas are feverish is a popular error that has been fanned into faith by the willfully bought experience of the few. Carelessness and imprudence will bring about their own results anywhere, and unfortunately people seem to display a larger share of both when once they get to the Hills. It is a common thing to see young and delicate children, sometimes fresh from the enervating heat of the plains, out in damp weather before the heavy morning mists have been dispelled, and again after sunset, when except in the driest weather, it is too late for them to be out. Exposure to the sun, violent exercise, neglect in changing wet clothes, are all causes likely to act injuriously on frames enfeebled by residence in the plains, yet when they are never avoided, and illness follows, the climate is blamed! The residents are healthy enough, but though acclimatised, they are careful to avoid the risks which some visitors indulge in freely, and never have cause to complain. As elsewhere we have been living in dread of the arrival of the demon influenza, but happily have escaped so far, though it is amusing to see the anxiety with which the symptoms of the simplest cold are watched till fully developed. The Tasbildar and all his clerks happened to feel ill simultaneously with feverish symptoms, and the alarm spread like wild fire that influenza had arrived, though every one looked foolish when no fresh cases occurred, and the attack was traced to a simple, and natural cause. An impression exists that this is the beginning of the most unhealthy season of the year, but as a matter of fact public health is particularly good just now, with even fewer cases than usual prevailing of the colds and coughs which, as a rule, accompany the trying changes from hot sunny days to cold dewy nights.—*M. Mail.*

INDIAN IRRIGATION.

The late Chief Secretary of Victoria, after visiting India, penned an able report upon what he had noted in regard to Indian administration. Summing up the conclusions at which he had arrived, the Hon'ble Mr. Alfred Deakin said that the legislation of India had not much to teach Australia, its administration little, its practices little, its relations of State department and people little, its agriculture very little, but that India's methods of construction, management of canals, conservation and distribution of water could teach Australia a great deal. Coming from the above authority and at tail end of a series of negatives, this remark is a high compliment to those entrusted with the care of irrigation in this country. Mr. Deakin alludes to the circumstances under which irrigation began in India as not unlike Australian circumstances. But he remarks that in this country irrigation provides fresh food fast, only to find the population increasing faster, and not permanently rising or likely to rise, in the social, moral or intellectual scale, to even a European standard. He studied Indian irrigation as an outsider, desirous of learning what the system could teach. He alludes to Indian Engineering designs and devices as worthy of acclimatization in the colonies; and reviews the working of the system in a highly appreciative manner. The reports upon which he based his remarks have now been succeeded by others. But these later writings

only tend to confirm the greater part of what Mr. Deakin has said. He wrote for a special purpose and touched upon some points which the Indian critic is content to take for granted. But the reports now published on the working of the Irrigation Departments in India during 1890-91, strengthen us in the belief that that country is fortunate indeed, which can truthfully say that it has nothing to learn from India in regard to irrigation. What is being done here is the outcome of centuries of native experience, followed up by European science. Irrigation must have been practised by Indians in very remote ages, and even the perennial canal of today appears to date back from the thirteenth or fourteenth century. But now, outside the Government schemes, the rain-filled tanks and the little wells are the chief source of native supplies. It is to these and not to the canals, or the tanks built by Mahomedan monarchs, that the people have trusted for centuries; it is to these that we chiefly look now for protection against a threatened water-famine.

In regard to irrigation we do not propose to dwell at great length on the usual test of a system, its financial results. These, if studied narrowly, would lead us to wrong conclusions; while to make clear the broad deductions that may be drawn from the annual returns, would occupy more space than we can spare. Suffice it for the present to refer to somewhat old figures which enable us conveniently to compare the cost of irrigation in various parts of India so far as concerns works which may be regarded as comparatively new. Here are the figures:—

	Expenditure.	Acres Irrigated
	£	annually.
Ajmere	160,000	36,000
Bombay	2,500,000	85,000
Sind	1,180,000	150,000
Bengal	6,000,000	550,000
North-west	8,000,000	2,000,000
Madras	5,300,000	2,400,000
Punjab	6,500,000	3,000,000

Madras, it will be seen, shows up well here. It has made large use of Native works, and has thus been able to reduce the average of costs. But if we add to the above Native canals used in Government schemes, the table given would be increased by many acres:—Burma, 200,000; Sind, 1,000,000 and Madras 2,500,000, making about 13,000,000, for £33,000,000, yielding 4 per cent net revenue. To this total must be added the immense extent of country everywhere but especially in the North-West and in Madras, supplied from wells and tanks by the people themselves, and also the totals of Independent States. That all the outlay thus incurred is highly profitable, can hardly be shown in actual figures; though we have ever before us the fact that without irrigation millions of people could not live and some millions would be decimated by famine every few years. Speaking broadly however, of the financial results shown in official accounts, Madras, the North-West, the Punjab and Sind show handsome profits in regard to irrigation; Bombay figures are healthy; while in Bengal irrigation has been found to be the cheapest and best means of fighting famine, and saving the public Treasury from ruinous drafts in bad seasons.

Turning now to portions of the reports for 1890-91, we find that in Bombay 221,464 acres were irrigated, as against 230,753 in 1889-90. The decrease is explained as due to the exceptionally good rainfall during the late season, which led to a reduced demand for water. The aggregate estimated value of the crops irrigated was 40 lakhs, and the working expenses per acre irrigated are returned at Rs. 35. In the Deccan and Gojrat the net irrigable area under command was increased from 533,313 to 535,762 acres. The area irrigated by all the works taken together was 75,901 acres, which showed a falling off of 10,698 acres, due to favorable rainfall. The total revenue realised was Rs. 60,813; while the working expenses amounted to Rs. 23,9615. Bengal reports allude to returns for Major Works as less favourable than in the preceding year. The large Canal Works are specially commented upon by the Government of India,

which mentions incidentally that there is now no reason for further delay in completing the Orissa project so far as regards detailed sanctioned estimates, but progress continues slow owing to the want of labour. As regards Major Works the net result of the year was a loss of Rs. 2,995; while when Major and Minor are combined, the net results are shown to be, Receipts Rs. 21,70,960; Working Expense Rs. 20,28,238; Interest payable to the Government of India Rs. 37,119; Net charge on Provincial revenues Rs. 22,44,49. The total outlay in Madras was Rs. 63,45,384; the total area charged as irrigated both for first and second crops 5,514,184 acres, and the total irrigation (indirect) revenues, exclusive of deductions and remissions amounted to Rs. 33,20,535. The net revenue it is observed, amounted to 6.95 per cent in the capital outlay of the works in operation; and this percentage would have been 11.80 were it not for the Kurnool-Cuddapah canal. Taken all in all, the above figures are satisfactory; and they give but a faint clue to the benefits derived from the works to which they refer. Although at the present moment we have to say that the shadow of Distress is cast over India, we may also safely assert that that shadow would be much darker and much more to be dreaded were it not for the steady care that has been bestowed upon irrigation, and the great advances that have been made.—*Madras Times*, March 11.

SIVA CHAMBER OF COMMERCE.

The Annual General Meeting of the Siva Chamber of Commerce was held at the Siva Club Hotel last Friday evening, the Chairman, Henry Alarks, Esq., J. P. presiding.

THE CHAIRMAN'S REPORT.

The total imports for 1890 amounted to £206,757 as against £189,393 for the preceding year; being an increase of 8.4 per cent.

Under the heading of exports, the value for 1890 is set down in the official return as £364,533 as against £364,282 being only an increase of £251, the smallness of which may be accounted for by the fall in price of one of the staple articles of export namely sugar, the diminution in value averaging £1 per ton; but as there was a total increase in value, despite the fall in price of one of the principal commodities, it is evident that the exports of the colony are considerably on the increase. As regards navigation I might mention that the total foreign tonnage for 1890 exceeded that of the previous year by 26,456 tons.

I will now make a few comments on some of the products of our colony.

TEA.—This is finding favour in all quarters and it is greatly to be deplored that the supply is in no way adequate to the demand. In fact for some months past a considerable quantity of foreign tea has had to be imported by local merchants; this marked increase in appreciation should prove an encouraging factor to producers, and it is to be hoped will lead to more widely extended cultivation.

BANANAS.—The export of this fruit is still increasing and from the large amount of fresh load being brought into use for the growth of bananas, it is to be concluded that the producers find the industry a profitable one, notwithstanding the many drawbacks they have to contend with.

COPEA.—1891 having been a very favourable year for the growth of coconuts and as new areas are coming into bearing, there is every reason to believe that the export of copra will be considerably in advance of former years.

DESICCATED COCONUT.—It is satisfactory to note the various kinds manufactured by the local companies are coming into larger and rapidly increasing demand, so as to necessitate a considerable increase of plant from time to time.

Tobacco.—Although so far there has been no export of high class tobacco from Fiji, there is some reason to hope that the year 1892 will show superior tobacco both for wrapping and filling cigars, entering into

favourable competition with other in the markets of the world.

SUGAR.—The growth of sugar-cane is considerably on the increase and during the past year, large areas in a completely new district have been put under cultivation, this being the forerunner of sugar works of considerable magnitude.—*Fiji Times*, Feb. 3rd.

SCENES FROM EASTERN DRUG-PLANTATIONS.

The scenes represented in the following illustrations are reproduced from Dr. Alexander Tschirch's book "Indische Heil und Nutzpflanzen, und deren Cultur,"* upon which we comment in another part of this issue. The work contains no less than 128 illustrations, reproduced from photographs, mostly taken by the author himself. The first view shows a cinchona-plantation in Java. The little seedlings in the foreground are a *Succirubra* nursery. When the time arrives to plant out the seedlings in a regular plantation two coolies carefully remove the covering of the young shoots, pull them out by the roots, taking care first to moisten the earth round about, so that it shall adhere to the roots, place the shoots on a tray, and cover them with Pisang leaves to protect them. Two other coolies carry the tray as quickly as possible to the plantation-ground, where the seedlings are at once replanted under European supervision. The trees in the background are a full-grown plantation of *Cinchona Ledgeriana*, Moens. While exploring the bark estates in Western Java, Dr. Tschirch was disagreeably reminded that living among the cinchonas gives no immunity from fever. On one occasion he was suddenly seized with malaria while standing under a magnificent Ledger-tree in Bandung, and had to ward off the attack by swallowing compressed quinine tablets, which the local pharmacist obtained all the way from Berlin. The first illustration on page 309 shows the late Mr. B. Moens, the assistant-director of the Java Government gardens, to whose indomitable perseverance the cinchona industry in that island owes much of its present position, reclining in the shade of his own cinchona-tree of the Ledger variety which bears his name. The plantation is a typical Javanese Kinatun, or cinchona-garden.

GRAFTING.

Great attention has been paid in Java lately to the intermixture of the cinchona varieties by grafting. The first grafting experiments were made as far back as 1866, in Teysmann's days. Director Van Gorkom afterwards devoted much time to the pursuit of this mode of culture, and the present director of the Government gardens, Mr. Van Romunde, believes that the grafting-process has a considerable future, in proof of which conviction he has caused it to be extensively resorted to in some of the gardens under his care—at Tirtasari, for instance. The grafting of the slow-growing *Ledgers* upon the strong, hardy, and quick-growing *Succirubras* has not, up to the present time, yielded favourable results, for it is found that a considerable proportion of the cinchonidine of the *Succirubra* is absorbed by the Ledger-graft, which is originally wanting in, or but sparingly provided with, this alkaloid; while, contrariwise, the quinine from the Ledger passes into the parent stem, the result being a tree containing less quinine but more cinchonidine than the trunk, a transformation which, needless to say, is not a desirable one.

Dr. Tschirch gives some striking instances of what we may term this alkaloid-exchange. A Ledger tree, raised from American seed, yielded 9.79 per cent. of quinine; grafted upon a *Succirubra*, the combination resulted in the production of a bark analysing only 7.32 per cent. quinine, but also 2.77 per cent. cinchonidine. From another Ledger, yielding in the natural state 11.01 per cent. quinine and no cinchonidine, grafting upon *Succirubra* produced a

* *Indische Heil und Nutzpflanzen, von Dr. Alex. Tschirch*. Berlin, R. Gaertner's Verlagsbuchhandlung. 10th cover, octavo, 223 pp., 128 illus. 30 marks.

bark yielding 8.61 per cent. of quinine and 1.11 per cent. cinchonidine. On the other hand the *Succirubra* trees become richer in quinine by grafting, the bark of one tree increasing its percentage from 1.5 to 2.7 per cent., that of another from 1.5 to 1.65 per cent. The book contains altogether fifteen illustrations showing the cultivation and preparation of cinchona, while the tea-culture claims seventeen, coffee six, and cocoa four.

NUX VOMICA.

The next view shows a full-grown *Strychnos* tree in the Government Gardens at Buitenzorg, near Batavia. The tree is a native of Ceylon; it attains a height of about 30 feet, and, notwithstanding its attractive appearance in the photograph, the author describes it as neither imposing nor beautiful—the flowers, plain, insignificant, of a yellow-green colour, contributing nothing to heighten the effect of the tree.*

THE TAMARIND.

The *Tamarindus indica*, of which the illustration shows a full-grown specimen in a thick plantation in Java is a tree of very different appearance. Neither in Java nor in Ceylon is it cultivated in regular gardens, but the beauty of its growth and the amplitude of its foliage have brought it into favour as a shade-giving tree. The tamarind appears at its best in the season when it is covered with its myriads of delicate flowers, or in the fruiting period, when thousands of long, fawn-coloured fruit-pods droop down from their long stalks. A tamarind-tree 50 or 60 feet in height is by no means rare but this altitude is only attained after many years, the tree being one of very slow growth. The great square in Batavia, the "Koningsplein," is shaded by magnificent avenues of tamarind-trees.

BENZOIN.

The benzoin-tree (*Styrax Benzoin*, Dryander)—in Malay, "Kayoo Keniuyan"—is a native of Sumatra and Java. The tree grows to moderate size—the specimen represented in the picture is about 40 feet high—its leaves, flowers, and fruit are of a plain grey colour, which does not add to its dignity or beauty. A Dutch planter in Java has established a benzoin plantation of 70,000 trees on the northern slope of the Salak volcano; but, although he imported labourers from Sumatra on purpose, and the mode of preparing the gum followed in Sumatra is known in all particulars, the culture does not appear to flourish very well in Java.

THE NUTMEG.

The last picture represents a group of trees in the Government Botanical Gardens in Java. The two large trees to the right are nutmeg-trees (*Myristica fragrans*, Hout.) The left part of the illustration shows *Elettaria speciosa*, some of the smaller Zingiberaceæ. The nutmeg-tree, says Dr. Tschirch, reminds the European traveller of the vegetation of his own home more closely than almost any other tropical plant. Its handsome, well-proportioned stem, the elegant pyramid of its richly-veined crown, the small leaves—all these peculiarities makes him think of the pear-tree of his own gardens, only that every part of the nutmeg-tree branch-formation as well as outline, seems more beautiful and noble. The average height of the tree does not exceed 30 feet, or its circumference from 8 to 10 feet, though in the wild state it grows twice or three times as high. The nutmeg-tree, it is true, does not shine by the magnificence of its flowers, which though abundant, and of a pleasant orange fragrance, are small, unobtrusive, and strikingly like those of the hawthorn; but its peach-sized, oval, pale yellow fruit peeps kindly through the verdure, and the vivid red arillus glancing through the burst fruit, and contrasting effectively with the dark brown seed-husk, imparts a strong and characteristic colour to the whole. The tree bears fruit and flowers simultaneously almost all the year through.—*Chemist and Druggist*.

* We thought the foliage of some young trees near Mihantale very pretty.—Ed. T. A.

A CITY OF PALMS.

Georgetown, the capital of British Guiana, may claim, with more right than any West Indian town, to be called a "City of Palms." Here, indeed, more than in any other place I have ever visited, do they, from their abundance and vigorous development, exhibit that majesty and grandeur, the story of which must have first won for the Order the title, "Princess of the Vegetable Kingdom." Whatever part we stroll, on every hand they appear, forming majestic avenues, rising at entrance gates in pairs with stately pillar-like columns, or scattered singly or in groups, in gardens or by road-sides, their pluming heads, tossing in the wind often a hundred feet aloft. West Indian towns, generally, abound with plants, and lie, as seen from some elevated point cubosomed in vegetation, but taking a general birds eye view of this city, nothing strikes the observer but the forest like abundance of palms. As seen from any of the elevated towers the view is exceedingly beautiful. To the back lies the Demerara river, which before the trade became monopolised by steamers, was crowded beyond any of our West Indian ports with shipping, and on the left the sea; while beneath and around, far stretching, are seen the white well kept, stores and houses over-shadowed and sheltered by the canopy of palm foliage. Looked at in this way some parts of the city that are fully built over and occupied seem to be pure unbroken coconut plantations, the streets and houses being hidden beneath the trees. Most of the tree stems are naked but others are clothed from ground to crown with the small repent fig, or with bright flowered free-growing creepers. It is surprising that this richly tropical effect is produced by only two species,—*Cocos nucifera*, the coconut, and *Ocotelea oleracea*, the well known cabbage palm of the West Indies. A few other kinds of introduced palms are found grown up in the town, but, excluding the public gardens, in numbers so few that they may be counted on the fingers of one's hands. The coconut tree is grown only for the sake of its valuable nuts, and is never planted to form an ornamental feature. The cabbage palm on the other hand, though of incomparably less utility, is planted only for decorative effect, being one of the most stately and beautiful plants in the order. It is spontaneously here as everywhere that it once obtains a footing, and its prevalence is probably as much due to its generative energy and constitutional vigour as to any particular taste on the part of colonists for its cultivation.—*Demerara Argosy*.

IN PRAISE OF CEYLON TEA.

Messrs. Gow, Wilson & Stanton write to us, under date 23rd Feb. :—

"The chief object of this letter is to forward the enclosed document which is somewhat unique, and the chief importance of which consists in its emanating from one of the largest retail tradesmen in London. Whiteley's shop, as you probably know, has an enormous patronage amongst well-to-do classes in England and, therefore, the circulation of this document may perhaps become very wide. Should this be the case, it may tend to still further increase the popularity and the sales of Ceylon Tea, and we therefore bring it to your notice as a step which may eventually prove of some benefit to the Ceylon Tea Trade."

The enclosure is as follows:—
AFTERNOON TEA AT WHITELEY'S.
1892.

"Jingla! Tinkla!" Teacup and Spoon!
O! the glad sound on a cold afternoon;
Refreshing aroma wafts all round me,
While sipping at Whiteley's his "Pure Ceylon Tea!"

Out on the pavement is nothing but snow,
Here within Whiteley's I feel a warm glow;
Dainties are brought me, I sit at my ease,
Partaking at Whiteley's of "Pure Ceylon Tea!"

All should come early, who wish to be served
Here without waiting, no tables "reserved";
In comfort you sit as long as you please,
Enjoying at Whiteley's his "Pure Ceylon Tea!"

How the wind blusters, and O! how it blows!
Keen too it cuts through the thickest of clothes
I feel impervious to any cold breeze,
Refreshed so at Whiteley's by "Pure Ceylon Tea!"

"Jingla! Tinkla!" Teacup and Spoon!
O! the glad sound on a cold afternoon!
Nothing can equal, O! do believe me!
The flavour of Whiteley's own "Pure Ceylon Tea!"
L. F. S.

We only hope that Whiteley's tea is pure Ceylon.

It may not be generally known that a good substitute for tea can be obtained in the Australian bush. It is a glabrous climbing plant, with stem and branch covered with prickles. Many persons call it Botany Bay tea, and others sweet tea. It has good medicinal properties, besides furnishing a tasty and refreshing drink.—*Indian Agriculturist*, Feb. 27th.

THE MARKET FOR CHINA TEA is not so strong, but the prospects are no worse, in fact, at low prices chances are in favour of a large spring shipping demand. In reference to next season's business the position is becoming clearer, for it seems to be unreservedly admitted that importing must be carried on very differently. A general improvement in quality may also be looked for, and that would undoubtedly go a great way to reinstate the China article to public favour. The great weight of inferior Indian and Ceylon Tea just now offering on the market is prejudicially affecting values, and it is a question whether such leaf would not be more advantageously prepared as brick tea. There is a largely increasing trade opening up *via* Tientsin in the north and north west of Asia. Ceylon could spare 15,000,000 to 20,000,000lb. of its increasing production to the benefit of all concerned.—*L. and C. Express*, Feb. 26th.

THE WATTLE INDUSTRY.—Messrs. Angus, of New Hanover, are going in extensively for wattle cultivation. Their enterprise may be said to inaugurate a new era in the industry, the application of scientific methods to the preparation for commercial purposes. It marks, in fact, a new departure in the industry, nothing of the kind having been tried before in South Africa or Australia. The buildings include a drying room, capable of drying some four tons of bark in some eight or ten hours, a blast of hot air being continually driven through the room by means of furnaces and a large fan. In other sheds are the steam engine and chopping machine for cutting up the dried bark together with packing and storing rooms, tanks, &c., the whole arrangements being so complete that the preparation of the material will doubtless go on in wet or dry weather with the regularity of a manufactory.—*Witness*.

COFFEE AT THE STRAITS.—It is satisfactory to know that at least one class of the community has benefited by the heat which most of us have found so trying during the past few weeks. We are informed that the blossoms on the coffee have surpassed anything that has been seen in those parts before; and that the exports of coffee for 1892-93 may be expected to beat the record. Prices also continue firm, and are likely to do so; the unsettled state of almost the whole of the South American continent making it impossible to obtain reliable information as to the probable output of that quarter of the globe. The tendency of belief at the same time being that the prevalent uneasiness there will tend to disorganise labour, a consequent diminution of production may be looked for. We feel therefore that we may confidently congratulate our Eastern coffee planters in the future before them.—*S. F. Press*, March 5th.

MAT MANUFACTURE IN COCHIN.

The following account of the history and manufacture of Wadakaucherry mats has recently been given in a report on the Agricultural and Industrial Exhibition held at Mysore in October of last year.

The mats are made at Wadakaucherry, a taluk of Cochin. They are known at the place by the simple name of grassmats, and are recognised elsewhere by the name of Palghat and Kavalapasa mats, other places of manufacture. The industry was introduced into Cochin from Kavalapasa about forty years ago. At first there was but one family engaged in the trade, it has now increased to three, consisting in all of twenty souls. Both males and females are employed in the work. The men were originally brought for making mats from the Sircar and were provided with free quarters. Such is the short history of the introduction of the industry into Cochin.

These mats are made, like the Palghat mats of a kind of sedge (*Cyperus Pangorei*), grown by the side of swamps and rivers. The sedges grow to a height of six feet, by one and a half inches in circumference, and are of a triangular shape. They are collected in the rainy season. The culms or stems are split, and the inside pith removed, and are then dried. Each stem may be split into from four to eight, or even twelve, according to the delicacy of the texture intended. The strips are then well seasoned and sown into mats. Women are mostly employed in the collection and splitting of the stems, while the actual weaving is done by men. The loom used for the purpose is of simple construction, consisting of two bamboo pieces at either end, attached to pegs driven in the ground. The warp consists of twine made of country hemp, and is produced by the weavers themselves. In special cases cotton-thread is also used instead of twine. The process of weaving is done by the strips of sedge being passed to and fro crosswise, by means of a stick with a whole at one end of it to which the sedge is attached. The warps are passed through a moveable piece of wood with as many holes as there may be warps, and are tied up to the bamboo pieces at either end. According to the number and nearness of the warps the greater is the delicacy and strength of the texture. The wool is made compact by means of the piece of wood above described.

The distinguishing peculiarity of the Wadakaucherry mats is their brilliant colour. Only four varieties of it can, however, be had, namely, the white, black, red, and yellow; of these the last is the readiest to fade, and is obtained from a peculiar solution of turmeric and cassia leaves. White is the natural colour of the strips when properly prepared; red is obtained by boiling the strips in water containing sapan-wood and cassia leaves; black is but a conversion of red by a peculiar process of boiling the red strips in a solution of gall-nuts and green vitriol, and by subsequent soaping in a preparation of black clay. The difficult and dexterous portion of the work is the splitting and dyeing of the strips, the same has to be coloured with different colours, and this has to be done very carefully with reference to the size of ornamental work intended to be produced. When one colour is being worked at, the rest of the strip which has to be coloured differently will be closely covered with the outer covering of the plantain tree. The process of drying and dyeing the strip may take a fortnight.

Natives use the mats as seats, and also for mattresses in the hot weather. A sort of social distinction is associated in the offer of these mats as seats, and amongst the vulgar, disregard of it on ceremonial occasions tends to foment disputes. These mats are also used for flooring, and are then woven to the size of large halls and rooms. The mats vary in price from 1 to 10 annas, while the superior kinds fetch from 15 to 25 rupees, according to quality.

Experiments have been made with other colours besides those just mentioned, but hitherto without success. If the industry were carried on by organised capitalists, these experiments might perhaps be successfully repeated, and many other improvements

effected, such as facilitating the splitting of the sedge and keeping it compact by means of mechanical aid, and also relieving the weavers from the stooping they have always to assume when engaged in the work.

The mats of Wadakaucherry, compared with those of Tinnevely, are generally superior in colour and ornamental work, but are less pliable, though the strips are sometimes more delicate.—*Journal of the Society of Arts.*

COMPRESSED OR TABLET TEA.

In January of the present year two samples of compressed or tablet tea were presented to the Museum by Colonel Alexander Moncrieff, c. b., accompanied by the following letter addressed to Sir Joseph Hooker.

15, Vicarage Gato, Kensington, W.,
24th January 1890.

My dear Sir Joseph,

I had almost forgotten to send you the specimens of "tablet tea" which I spoke of at the Athenæum, but as soon as I saw it just now I recollected my promise, and here it is.

My Chinese correspondent, Mr. Gardiner, Her Majesty's Consul at Hankow, informs me that this tablet tea is in use throughout Russian Siberia. It is manufactured at Hankow, the larger tablet from common tea dust, which adheres after being steamed in a pudding cloth for a moment, by hand pressure. The quantity of the dust required is placed in the bag, and after being steamed, is poured into the wood mould, and is pressed to the required consistency by lever or a heavy mallet wielded by one of the labourers. The cost of the common tea dust is 3½ Chinese ozs. silver (say, 15s.) per pecul=133 lb. avoirdupois. The cost of the manufacture, export duty, packing, &c. amounts to a further 15s. a pecul. The bulk when packed is only one-sixth of the bulk of an equal weight of ordinary tea as ordinarily packed.

"The small tablet is made of the finest tea dust, the selection of which is made with great care. The original cost of this tea here is about 8s. a pecul. It is manufactured into tablets by steam machinery in a steel mould. The proper amount of dust is poured into the mould dry without steaming, and the pressure brought to bear upon it is two tons per tablet. Considerable care is required in the manufacture and packing of this tablet tea, and the cost is comparatively great.

"Besides this tablet tea used in Russian Siberia, there is a pressed tea called brick tea used in Chinese Mongolia and Tibet. This is made of the whole of the leaf with stalks, and is about the size and shape of an ordinary brick. I have not seen this tea manufactured. It is made, I know, by Chinese in a very simple way.

This is all the information I got with the specimens.—I am, &c. (Signed) A. MONCRIEFF.

Sir Joseph Hooker, K.C.S.I., F.R.S., &c.
The manufacture of compressed tea at Hankow, referred to in the above letter, seems to be an industry of considerable importance, and is fully detailed in an article from the *Planters Gazette*, reprinted in the *Tea Cyclopaedia* issued from the office of the *Indian Tea Gazette*, Calcutta, and published by W. B. Whittingham & Co., 91, Gracechurch Street, London, in 1882. It is there stated that "the Commissioner of Customs at Hankow reports that the importance of the brick tea trade is rapidly increasing, and the demand becoming greater than the supply. The employment of steam machinery for pressing the bricks has proved in every way a great success, the steam-pressed brick being much better finished than that produced by hand, and more compact and firm, withstanding the difficulties of transit better, and ultimately arriving at its destination in Siberia little, if any, the worse for the journey. With the old method, the bricks, from insufficient pressing power, were liable to chip and crumble at the edges; and as great stress is laid on perfect appearance of the brick by the Siberians, it can be

easily understood that a hard, sharply defined brick would at once obtain the preference. With both methods of manufacturing brick tea, there is a drawback, and a serious one—the damping of the dust by steam, which robs it of all its fragrance. To remedy this defect, a firm has imported a hydraulic press, which turns out small corrugated cakes, weighing a quarter of a pound each retaining the original aroma in all its freshness."

It was considered very probable that the ordinary brick tea and the compressed tea would run side by side in friendly competition, the brick keeping its own position for use amongst the poorer, and the compressed tea becoming popular amongst the better classes. At the time the article was written from which the preceding extract is made, there were six manufactories in Hankow, in three of which boilers were used either for steaming the tea, or both for that purpose and furnishing power for pressing. The dust from which brick tea is made comes principally from Ningchow in Kiangsi and Tsung yang and Yanglont'ung in Hnpeh, and varies both in fineness and cost according as it belongs to the first, second, or third crop.

The Commissioner proceeds to state that—

"The first operation is to sift the dust and reject all the sand and rubbish contained in it, usually amounting to about five per cent. It is then placed in a winnowing machine having three different sized sieves, with troughs corresponding, and passed into baskets. The residue, which is too coarse to pass any of the sieves, is taken out and trodden until it is reduced to the proper consistency, when it is placed in iron pans over a charcoal fire until it is sufficiently brittle, when it is again taken to be winnowed, and this operation is repeated until it has all been sifted to the requisite degree of fineness. Three sizes are produced, the coarser ones being employed to constitute the brick, while the finest dust is only used as a facing. The dust having been properly sifted the next step is to prepare it for pressing, and this is done by exposing it to the action of steam for three minutes, and it is this steaming that robs brick tea of its scent and flavour, and for which a remedy is eagerly sought.

"The old fashioned native apparatus consists of six iron boilers heated by charcoal and having spaces above, which are fitted with rattan covers. When the dust is to be steamed it is spread out on a sheet of cotton cloth placed over the boiler and covered up; but with the improved European apparatus the dust is simply put into iron boxes and the steam there passed through them. After having been sufficiently steamed to make it adhesive, the dust is put into a strong wooden mould, on the movable cover of which the trade mark of the 'hong' or firm is engraved (so as to leave the corresponding impression on the brick) and firmly wedged down. It is then pressed and placed on one side for two or three hours to cool. Each brick should weigh one catty (1½ lb.), and all those that do not come up to the proper standard of weight or are defective in any way are rejected and re-made. For this purpose they are taken to a rotatory mill, constructed of two heavy circular stones moved by a horizontal wooden bar and working in a channel where the condemned bricks are thrown, and crushed as the wheels pass over them. Having again become dust, the operation already described is in all its details repeated. The hand press turns out 60 baskets a day with 25 per cent. failure bricks, while the steam press produces 80 baskets a day, with only five per cent. of bad work, and the saving by the employment of the improved machinery amounts to one tael a basket, or, according to the above stated outturn, eighty taels a day, or about 20%. The bricks found to be correct in weight and free from defects are stored in the drying room for a week, when they are carefully wrapped, separately in paper, and packed in bamboo baskets containing 64 bricks each. Green brick tea is made in the

same manner, but of leaf, not dust, and the bricks are larger, weighing two pounds and a half each, thirty-six going to a basket when packed for export."

There is a sample of hard compressed brick tea in the Kew Museum such as was imported in quantities into London from Shanghai in 1863, for re-exportation to Russia, the cost of which was 6d. per pound and duty. It seems from information kindly furnished by Mr. Henry Tuke Mennell, F.L.S., of St. Dunstan's Buildings, Great Tower Street, E. C., who presented the above-named specimen to the Museum, that this kind of tea is not now an article of commerce on the London market, though it is still an article of regular consumption in Russia, but is now chiefly, if not entirely, sent overland.

Consul Allen, reporting on the trade of Hankow for the year 1887, says, "The trade in Russian brick tea seems to increase 'by leaps and bounds.' The bricks are prepared entirely by steam machinery. The brick tea factories, with their tall chimneys, are the most striking buildings in the European settlement."

The brick tea of Tibet is an entirely different quality of tea from the above described. The full grown leaves are used, and are comparatively loosely pressed together into blocks about 10 inches by 10 inches, and 4 inches thick.

Mr. Colburne Baber, some time British Consul at Chungking, described the Tibetan method as a wooded churn, in which the boiling infusion is poured through a strainer; a little salt is added, and some 20 strokes applied with a dasher pierced with five holes. A lump of butter is then thrown in, and the compound is again churned with from 100 to 150 strokes administered with much precision. The tea is then ready for drinking.

The use of compressed tea in this country has been attempted at different times, but never with complete success. A few years ago two companies were formed for working it, and at the present time there is a company in London which deals exclusively in this article, a sample of which is in the Kew Museum. It is claimed for this tea that it has many advantages over loose tea, the chief of which is that the leaves being submitted to heavy hydraulic pressure all the cells are broken, and the constituents of the leaf more easily extracted by the boiling water thus effecting a considerable saving in quantity required for use. Its great advantages over loose tea however would seem to be its more portable character, and in the case of long sea voyages, or for use in expeditions, the reduction of its bulk to one-third.

The compression of tea into blocks further, it is said, constitutes a real and important improvement in the treatment of tea. These blocks weigh a quarter of a pound each, and are subdivided into ounces, half ounces, and quarter ounces; this insures exactitude in measuring, and saves the trouble, waste, and uncertainty of measuring by spoonsful. It also ensures uniformity in the strength of the infusion. By compression it is claimed that the aromatic properties of the leaf are retained for a much longer period, and that it is better preserved from damp and climatic changes.—*Kew Bulletin*.

THE CORK INDUSTRY IN SPAIN.

The cork tree is found in Spain in great abundance in the provinces of Gorona, Carceres, and Andalusia, especially in the provinces of Huelva, Seville, and Cadiz, and, although in less quantity, in the provinces of Ciudad Real, Malaga, Cordoba, Toledo, and some others. The United States Consul at Barcelona says that, according to a calculation made by the administration of forests, the extent of cork forests in Spain is about 256,000 hectares (hectare=2.47 acres), distributed as follows:—80,000 in the province of Gorona, 45,000 in Huelva, 32,500 in Carceres, 28,000 in Seville, 20,000 in Cadiz, 11,500 in Ciudad Real, and 9,500 in Cordoba. In the localities exposed to the north the cork is better than in those exposed to the south, and it is seldom found in calcareous soil, preferring always that of the felspar, this being found principally in the pro-

vince of Gerona. It grows and develops in ground of very little depth, and sometimes in very stony ground. The leaves of the cork tree are oval-oblong or elongated oval, frequently toothed, and the teeth jagged; length, from three to five centimetres, and width from one and a half to two. The roots are strong, and spread considerably, and are frequently to be seen on the surface of the ground. It sometimes happens that the portion of root exposed to the air produces cork, while that which is buried produces scarcely any. The most common practice is to cultivate the plant by sowing, which is frequently done, especially in ground somewhat manured, making alternate furrows with vines. Up to their twentieth or twenty-fifth year the ground is cultivated as if it were a vineyard, rooting up at that age the vines on account of producing less fruit, and also on account of the cork trees being fairly grown up, and no longer requiring the shelter of the vines. The barking of the cork may be effected when the plant has acquired sufficient strength to resist the operation, and the time chosen for this operation is in the summer. The cork of the first barking is called *corcho barnio*, *barnizo* or virgin, and is not fit for making corks. The cork taken after the first barking is called *pelus*, or secondary cork. The method employed in Spain for this operation consists in the total barking of the trunk, and not partial barking, or barking one part of the year and the remainder three, four, or five years later. In proportion as the cork is taken from the tree it is removed and piled up in heaps. Sometimes the cork is cooked in the woods, but at other times this operation is effected in the cauldrons that exist in the cork factory. The slabs remain in boiling water during the space of one hour, this operation causing an increase of thickness (generally of one-fourth to one-fifth), elasticity of the cork, and dissolution of tannin and other substances. The cauldrons in which the cork is boiled are of copper, and are either cylindrical or rectangular. The boiling of the cork can also be effected by steam, for which purpose it is introduced into a wooden box lined on the inside with copper or zinc, which is filled with water and steam injected therein. The steaming of cork sometimes hardens it and makes it brittle. The loss of weight produced by boiling the cork varies between twelve and forty per cent. In making corks it is necessary to take away the hard crust or *raspa*, for which purpose a tool is used with a short handle and curved blade, called *doladera*, *raspador*, or *rasqueta*. A workman can scrape from two to three square metres of cork daily, and the loss in weight of the cork by scraping is from twenty to thirty per cent. Scraping machines are also used, two systems being employed, the Besson and Toussaud. The former, propelled by steam, consists principally of horizontal spindles, supplied with comb-like teeth, and turning with great velocity, at the rate of nine hundred revolutions a minute. The Toussaud scraper attacks the cork by the means of a vertical iron shaft, carrying several knives, whose edges are also vertical, and by the rotary movement of the shaft, giving fourteen hundred turns a minute, work like a brush. This machine is simpler than the Besson, and the slabs suffer less damage when worked by inexperienced workmen. Before cutting the slabs in strips they are cooked for about half an hour, so as to facilitate the cutting, and piled up soon after in a damp place, so as to preserve the softness until ready to operate upon. The slabs are divided into three strips (*rebavadas*), the width of which is equal to the length of the corks, and in such a way that if the cork be placed in the position occupied by the slab on the tree they would have their fibres running alike. The workmen obtain or cut the strips by means of a knife with flat surface and curved edge, called *cuchilla de rebanar*. The strips are then made into squares by means of the *cuchilla*. They then have the edges cut, and thus prepared they are ready to be made into corks. This and the preceding operation are the most difficult of the cork industry, requiring great intelligence if the slabs and strips are to be cut to the best advantage. In the manufacture of the corks, the squares made into

octagons first pass into the hands of the workman who is furnished with a knife composed of two pieces one of them similar to an ordinary knife and the other a blade, the edges of which fits into the first. Consul Schenck says that only by seeing is it possible to form an idea of the rapidity with which these men take hold of a square and from it make a cork—they hold the knife by a small iron catch to the table in front of them, and giving to the square a circular movement, the result is that the cork is made in a few seconds. The squares are usually boiled for about a quarter of an hour, they are then deposited in a cool place, and four or five days after they are sorted and kept damp until required. The amount which the workmen receive for cutting 1,000 corks varies from 0.75 to 4 pesetas, according to the kind of workmen (the peseta is equivalent to about 9d.). Different systems of machinery are employed to make corks, and all consist, at the base, of a knife, the blade of which is placed horizontally, joined generally to a piece of wood, and to which a back and forward movement is given similar to that of a carpenter's plane. In moving, the knife turns the square cork, which being attacked by the knife takes off a strip of cork, more or less thick, according to the distance from the axle of the cork and the edge of the knife. If these are parallel, the result is the cork is cylindrical, and if it is not it becomes conical. The corkmaker or workman has a large basket or several of them in which he places the corks according to size or quality, but this first classification is not sufficient, and the corks are placed upon a table, the back part of which is furnished with boxes, the front part of which are open to the operator. To classify the corks according to size, they also employ wooden boxes, the bottoms of which can be taken out or put in, having a kind of grating of wood somewhat resembling venetian blinds. The boxes are suspended by ropes to the ceiling, and the workman gives it a swing backwards and forwards, by which the smaller corks drop out at the bottom. With this apparatus worked by one man, 100,000 corks are classified for their size in one day. The corks are washed in a solution of oxalic acid or biexalate of potash. As soon as washed they are placed out to dry gradually in the shade, in order to enable them to retain the silky gloss which the cork has when it is damp. For packing, 30,000 corks constitute what is called a bale. For South America and Oceania, bales consisting of 5,000 to 10,000 corks are made, and for England the sacks or bales are made to contain 100 gross or 14,400 corks for those of the larger size, and 150 gross for those of smaller dimensions. The greatest number of corks are manufactured in the province of Gerona, and the most important towns engaged in the industry are San Feliciu de Gnixels, Palafrugoll, and Cassade la Selva. The number of workmen engaged in the cork industry in Spain is said to be not less than 12,000.—*Journal of the Society of Arts.*

COAL AND IRON IN INDIA.

The recent news from home about the serious strike in the coal trade may have a most important bearing on these products of the East. It is often forgotten that the Indian Government is probably the largest owner of these two pillars of prosperity in the civilized world. There are thirty thousand square miles of coal strata in India, the corresponding area in England is less than twelve thousand, and, says Phillips, all the European fields do not contain as much coal as the coal measures of Great Britain. In the United States and China alone there are, it is believed, coalfields surpassing those of India and England in area and value. England has been using up her coal recently to the extent of about one hundred and fifty million tons per annum, the output having increased from sixty-four millions in 1855, and the export having more than tripled in twenty-three years. Such being the rather alarming situation, in 1863 a committee was held to discuss the exhaustion of our coal beds and the probable duration of our remaining supplies.

Opinions differed, Professor Jeovns and others held, if we remember right, that in all probability our cheap coal would be exhausted within a hundred years, while owing to panic or combination among owners or workmen, there might be at any time an appreciation of coal and iron which would drive the English consumer to foreign sources of supply, and be ruinous to much of our industrial supremacy. It was believed in 1868 by those who took a sanguine view, that the consumption of our coal would not exceed the amount to which it had then risen, exactly one hundred millions of tons, because it was supposed that by hot blast, smoke consumption, close-topped iron furnaces and other appliances, we would economise to such a degree, that the increased consumption and export would be more than balanced. As we have seen this prophecy was not verified; the output rose above fifty per cent in a few years, and England now stands face to face with the apparent certainty that all the good coal within two thousand feet of the surface of her soil will be exhausted during the lives of thousands who have been already born. As was prophesied, there have been several notable appreciations of coal and iron; in 1873 steel rails rose to £15 10s per ton, having since been as low as £4 10s. This was due to temporary causes, but the last news, from home seems to point to a determination on the part of both masters and workmen, that the public must in future pay much higher than present prices for coal and iron. There is nothing in the general state of trade to warrant the reduction of wages which the masters have found necessary; there is no strike for eight hours' play and eight shillings a day; there is no grasping at better standards of comfort and living; we see nothing but the inevitable and long foreseen result of unlimited production and consumption of iron and coal, both having been accelerated in a high degree by our system of free trade.

It is desirable then to consider what can be done in the Eastern dominions of the Crown to reduce the balance which seems as if it were about to incline seriously against us. The Inquiry is still more interesting, because during the present year Government will commence the manufacture of steel shells at Cossipore, and it is hoped that more general and extensive operations will be undertaken when satisfactory results are shown in one item. The advantages which India possesses over England or Germany in iron metallurgy are notable. First, there is an abundance of the finest ores, such as are absolutely required for the Bessemer manufacture, which for years past has sent into the world annually above three million of tons of steel. If again we wish to apply the basic process and consume the phosphoric ores which are also plentiful, dolomite is abundant in India—witness the marble rocks of Jubulpore—while it is scarce and expensive in England. It is well known at home that pure iron ores containing up to 97 per cent of ferrioxide abound in India. To discredit them interested or ignorant parties have got up the cry that there is no good lime in India. The standard work on steel-making Mr. Jeans published as late as 1880, contains the information that India suffers from a want of lime, though many years before that date analysis had proved that limestone of unsurpassed purity covered thousands of square miles round Satna and Katni. We are also told that firebrick clay is wanting, though Mr. Hughes found abundant supplies near Jubulpore, and an English firm has recently made firebricks from the clays beside the railway station. Iron is manufactured at a cost of £14 per ton in Knnaon, says Mr. Jeans; but the Government Geologist reports the cost of making steel in 1888 to be £2 per maund, or £3-12 per ton at present rate of exchange. If such results are achieved without the uses of hot blast, or of permanent furnaces with apparatus of the most primeval type, what may we not expect from the adoption of modern improvements? It is true that the best coal is yet wanting in India, on the other hand, the best charcoal and wood abound, and are a waste product. The jungle fires in 16,000 square miles of Government forest consume timber which is useless for construction, which now vanishes in smoke and ashes, but which

might be utilised to turn the iron ores into steel rails, steam engines, and a hundred items required alike in industry and in war.

Denudation is dreaded by forest authorities who possibly are ignorant that in even inferior furnaces one ton of iron is produced by the consumption of thirteen hundredweight of charcoal. Charcoal may be made from inferior woods, such as *Boswellia* and *Sterculia*, or from crooked and worm-eaten boles; in fact the wisest forester admits that iron-smelting and forest conservation may co-operate to their mutual advantage when reboisement is fostered by heavy rainfall. With all these advantages and a falling rupee, how happens it that although steel-making by the Bessemer system was taken up in India in 1861, the project was nipped in the bud, and for thirty years no steel has been made here by European methods? How is it also that iron smelting has failed in Kumsou and Porto Novo, while it has succeeded in Barakur? The answer to these questions must be deferred to another occasion. It may be noted, finally, that charcoal is still largely used for the production of the finest qualities of steel and iron in Sweden and the United States, where forest reproduction is much slower, and labour far more costly than in India. The finest qualities of steel are those which State railways and arsenals demand in annually increasing quantities. Strange to say we import ores or iron from Sweden, Algiers and Bilbao. We actually construct lengthy railways solely for ore carriage, we turn those imported ores into steel by the aid of coal, of which our supplies are threatened with extinction, and then send the finished article to Allahabad or Agra, paying thirty shillings per ton for carriage alone, while all the materials for steel manufacture exist actually under the railways which carry the costly foreign product. Soon we trust Bessemer Converters will be soon operating on Indian ores again: no royalties are now required; hundreds of millions have been added to the world's wealth by blowing air bubbles into big iron pots. India should now realise these marvels, and share in the gain.—*Pioneer*.

THE TEA INDUSTRY.

On the 3rd instant the last of the Indian tea crop, 1891, virtually passed the hammer, and before entering on the prospects of 1892 a retrospect may be desirable. The averages realised during the past season, as the reports of the various companies now appearing in our columns prove, have been little short of disastrous, and better quality must be the aim. A casual survey of the reports seem, in our opinion, to evade the real issue, which is nothing more nor less than over-production both here and in Ceylon, and the inevitable result must be the survival of the fittest. The averages must surely open the eyes of proprietors to the fact that to sell tea at five annas per lb., and even lower, which costs more to produce, can only result in liquidation. The various reports teem with the promise that every attention will be paid to manufacture in the future, as if it had been neglected in the past, and then hopeful results appear in print about 1892—"a superior class of tea will be produced, or an entire change in the management will be a necessity." In the face of the annual depreciation in the London market, and a further annual increase in output, we venture to think that a prediction of this sort is purely delusive. The great question that presents itself is, have we reached the lowest point of economy in the cost of production, or is there any step yet to be taken?

Machinery has effected much in that respect, but, on the other hand, the brain of the inventor has involved an outlay that seems to be endless, and no sooner is one machine pronounced the name of perfection than forthwith comes another that is predicted to perform double the work at less cost. It therefore strikes us that the expense of local management and supervision is far beyond actual requirements, and in this direction and the amalgamation of neighbouring properties must we look in future for further economy; and in advan-

eing this opinion we are guided in a great measure by what is called the labour difficulty. Only a short time ago the Magistrate in one of the recruiting Districts drew a sketch which was doubtless slightly the outcome of imagination. At the same time it conveyed much truth, namely, ten sirdars or recruiting agents staking one coolie as a recruit, and these ten sirdars represented ten different gardens within a ring fence of about 20 miles. If, on no other grounds, this alone to us seems conclusive proof that the labour difficulty is much in the planters and agents' own hands. Combination of planters and agents has been tried time after time, but either their interests are so conflicting, or their jealousies so great, that it has hitherto proved a failure. Shareholders are impassive; many of them have so long been accustomed to no return on their investments, that all efforts in that direction seem to be hopeless.

The only chance of effecting the further economy we have suggested is by a few resolute men who are deeply interested in the tea industry acting as a committee and formulating a series of schemes that by amalgamation will show a sensible decrease in the cost of production, and thus aim a great blow at one of the present curses of tea gardens, the cost of either imported or what is called free labour. Then it may be hoped that the difference between the cost of production and the value received for the manufactured article will show a margin commensurate with the outlay involved. It is with profound regret that we read in many of the reports that so much of the present misfortune that has fallen on the tea industry is laid at the doors of the unfortunate managers. Only those who have actually undergone the hardships, anxiety, and solitude of a planter's life can form an idea of what such an existence is, and, considering the small pay that they receive, and in most cases how much their emoluments depend on their exertions, it is not in that direction and by offering them up as the principal scapegoats that shareholders and proprietors must depend in future for some return on their money invested. Our advice, therefore, is to unite, and thus force down the cost of production by the saving in European supervision and the present reckless and expensive process of scrambling for labour.—*Correspondent of the "Englishman."*

CINCHONA IN MADRAS.

No industry in India has presented so many features of doubt and uncertainty as the cultivation of cinchona. Thirty years have elapsed since Mr. Markham advised and directed the introduction of this South American tree into the Nilgiris, and Mr. Melvor gave practical effect to his advice and instructions, and yet the questions anxiously discussed at the present are of an initiatory character—what are the best varieties to grow, how to grow them, and in what manner is the harvest to be gathered and placed upon the market? This uncertainty is all the more singular because cinchona planting is carried on by a fairly intelligent body of Englishmen and by the Government, which makes a speciality of the subject, employing highly trained experts to watch its progress and record the results of investigations in the field, the factory, and the laboratory. Thirty years may not seem a very long time for the conduct of a State undertaking; but for an experiment it is a fairly reasonable period, that ought to produce decisive results of one kind or another, encouraging or discouraging. With such advantages as have been enumerated, we have not advanced beyond the threshold of enquiry, and notwithstanding the great uncertainty on important matters, the cultivation, most unusual as it is, has advanced with rapid strides, and a vast area has become covered with a tree of which the growers know really very little.

The *Madras Mail* and the *Madras Times* had a résumé of the annual report on the Nilgiri plantation for 1890-91 with some commonplace observations thereon. It is true that, in maintaining its cinchona plantations, Government is doing for the planter what individual effort, or, for the matter of that, corporate effort, could not accomplish—namely, the investiga-

tion of the numerous problems and difficulties that have to be solved and overcome by the successful cinchona planter. Our present object is rather to dwell upon a few points of interest to the cinchona planter, which the labours of the Director and the Quinologist in the past have made prominent. From a number of experiments conducted on the Nilgiri plantations there is little room to doubt that the best variety of cinchona for the Hills is the *Magnifolia*. It is the hardiest and quickest-growing of all tin varieties, attaining to a considerable size comparatively, and forming thick bark rich in alkaloidal value. A recent analysis of the bark of the *Santa Fé*—to which Mr. Cross devoted attention when he was in India—shows it to be hardly inferior to *C. officinalis* in quinine, and much superior to *C. succirubra*. Like the *Micrantha*, there was an utter absence of quaidine in the bark, a constituent present in all cinchonas. The *carthayina*, it seems, is worthless on the Nilgiris. It was imported originally on an analysis of the *Magdalena*, but it is possible the latter never reached this country. Analyses both in Madras and in Bengal prove it to be entirely deficient in quinine. Mr. Heeper's enquiries into the constituents of the bark of the *Verde* and the *Morala*, two valuable varieties of the *colisaya*, lead him to predict a grand future for these kinds. Some seeds were obtained many years ago for Government from Bolivia, and plants raised from them on the Nilgiris and at Darjeeling. The elevation of the Nilgiris appears to be inimical, but they have thriven well in Wynad at 3,000 feet above sea level. A specimen of the *Verde* six years old, grown in the Wynad, yielded seven per cent of sulphate of quinine, and more recent analyses confirm this excellent result. With such a high percentage the *Verde* is almost better than the *Ledgeriana*, and deserving of extensive propagation. The experiments conducted on the Madras plantations with manure are particularly interesting and tend to show that suitable materials produce decidedly profitable results. It has been found that manures act more energetically on young trees than on old ones, and that the larger output of bark from the faster-growing varieties, like the *succirubras*, the *ledgers*, and *hybrids* and not from the slow ones as the *officinalis*. Cattle manure proved to be the most powerful fertilizer, raising the yield of quinine by about 50 per cent over that of manured trees. Lime, and lime and cattle manure mixed, were the next best, increasing the quinine by 20 per cent. Woodashes the least stimulating,—only increasing the sulphate by ten per cent. Peonae was tested as a manure, firstly, six months after application, and next twelve months after. In both cases there was benefit—in the latter to the extent of 22 per cent. In this experiment a singular effect was noted—the peonae reduced the quantity of *cinchonine*, the least valuable constituent of the bark. Fish manure applied for a considerable time proved to be as valuable as cattle manure, causing an increase of quite 50 per cent of quinine. Bone used with cattle manure produced an increase of 30 per cent, and hence alone 23 per cent.—*Indian Agriculturist*, Feb. 20th.

SOUTH SEA ARROWROOT is the product of *Tacca pinnatifida*, Forst. This is a perennial herbaceous plant, with a tuberous root. As a source of arrowroot the plant is of great value. The tubers when fresh resemble new potatoes, and contain a great deal of starch. *Tacca* arrowroot is preferable to any other in cases of dysentery and diarrhoea.—*Chemist and Druggist*.

BANANAS seem to have been imported in great quantities into England this year. Of all the vegetables which furnish food to man this fruit is the most prolific. A single cluster often contains from 160 to 180 pods, and weighs from 60lb. to 80lb. Humboldt says that a piece of land of 120 square yards will produce 4,000lb. weight of fruit, while the same area will rarely produce more than 30lb. weight of wheat or 80lb. of potatoes.—*Princess*

ESTIMATES OF THE TEA CROPS.

It is satisfactory to learn that Mr. Roberts, of Messrs. S. Rucker and Co., whose views as to the position occupied by our teas in the London market have been so repeatedly verified, has expressed the opinion that whatever the outcome of this year's crop may prove to be, whether in excess of or below the estimates made by ourselves, it is not likely to affect prices to be obtained for our teas. Several years ago, our readers will remember, Mr. Roberts told our London correspondent that, even if the time came when Ceylon should export 80 million, or even 100 million, pounds of its tea, an adequate market could be found for it. Indeed Mr. Roberts, while naming those figures, stated that, so far as he as an expert could foresee, there need be necessarily no limitation to the export. The sole effect of this, whatever its amount might be, would, in his judgment, be the displacement of a similar amount of China tea. To such a view, it appears, he still adheres; and his former prophesying has hitherto been so entirely justified by results, that we must perforce feel bound to attach great weight to his opinion. China tea is, as Mr. Roberts predicted it must be, succumbing year after year as the result to the production of this island having been placed in annually increasing quantity upon the London market, and although the assurance derived from this fact could not justify us in abstaining from making every exertion to open up new sources of consumption, we may take it for granted, we think, that up to the utmost limits of the capacity for tea-growing in Ceylon means may be found for its profitable disposal. We learn that Mr. J. L. Shand, who, during his late stay in Ceylon, has been actively engaged in visiting our upcountry estates, has written that he believes our export of tea for the year now current will be barely up to 74 million pounds. That gentleman has further written, we understand, that he has seen many fields, the bushes on which have shown unmistakable symptoms of having suffered from over-plucking; and he argues from this that, unless more discretion be exercised, many gardens that have hitherto annually yielded large crops must gradually show a great falling-off in their production. We have little doubt that in this opinion Mr. Shand will be supported by many other experienced planters. Bushes that have never been allowed any chance of attaining a certain amount of maturity for their leaves that have been constantly stimulated towards reproduction of bud by denying to their sap its natural outlet must, like all forced forms of growth, suffer ere long, and must need a period of rest for recuperation. The fact stated by Mr. Shand might perhaps well account for the difference between the estimate first made by ourselves and that his late experience compels him to adopt. If we had heard of Mr. Shand's figures without the assurance given us by Mr. Roberts, we think it might have been justifiable to assume that his reduced estimate would have been one upon which our planters and others interested in tea might be congratulated. But Mr. Roberts tells us that if our original estimate had been likely of fulfilment we need not to have feared from the fact that any lowering of prices obtainable for Ceylon teas would result. As it is we believe we may look upon the issue to this year's operations, whatever it may be, with almost entire indifference. Of late many alarmist predictions have found utterance as to the probable consequences of our greatly increased production, and there are many who with ourselves have attached an importance to them which we now

hardly think they can be said to deserve. It must, at all events, be some time yet before our exports can rise to the figure of 100 million pounds, at which it may be that Mr. Roberts would feel disposed to reconsider his present decision respecting this matter; and we fully adopt his view that until that figure of export be reached we may regard the extension of tea cultivation in this island with a satisfied calmness. This is, however, but one light in which to regard the facts communicated to us. The second in which these may be viewed is of importance as regards the financial prospects before our planters. If the tea bushes are to be weakened by a course of overplucking systematically pursued, it is possible that it will be found that planters will have to face a large destruction of trees on their estates. They will in fact find that they have "killed the goose that laid the golden eggs," and they will have to lie by to await the attainment to maturity of new trees put in to take the place of those which have been killed by persistence in an unwise course. And it may well be assumed, we think, that for recent largely increased exports this system of over-plucking has been largely responsible. It will be well, perhaps, if the diminished estimate of yield made by Mr. Shand opens the eyes of all of us to check the prosperity of our planting enterprise is likely to receive by persistence in a course which in the long run must, as it seems to us, prove very uneconomical. It will be better that we should be contented with lighter returns from our estates than that we should find ourselves compelled to in many cases lie by for several years to obviate the effect of excessive plucking in the consequent destruction of our trees.

SCIENTIFIC TEETOTALISM.

[The following is a specimen of the extravagant nonsense in which others besides Sir Andrew Clarke indulge. Tea is valuable as a food as well as a non-alcoholic stimulant. The use of tea has greatly increased the value of life and even its abuse is not to be compared for a moment to the ravages of alcohol.—Ed. T. A.]

In the current number of the *Australasian Medical Gazette*, Dr. J. Murray-Gibbes, of Boort, Victoria, has an interesting paper on what he calls "Scientific Teetotalism." After admitting that the teetotalers are right in saying that alcohol in fermented liquors is injurious to the body, he proceeds to ask whether teetotalism as carried out now is advantageous to the human race and how it is carried out.

"It is a total abstinence from alcoholic stimulants. But are those the only stimulants consumed now-a-days? By no means so, for in no period of the world's history has the consumption of stimulants been so prevalent as at the present moment. But it may be said, how can this be when teetotalers who now master by the thousand, never touch stimulants? Don't they? Why they consume as much, or even more stimulants than the non-abstainers, for instead of taking them in the form of alcohol they take them as tea and coffee, for their caffeine is as strong a stimulant as alcohol.* They have simply substituted one form of stimulant for another. Tea and coffee rapidly spread over Europe when it was first introduced in the seventeenth century, because it acted as a substitute for fermented beverages, in that the tannic acid in it delays the digestion of nitrogenous substances. There is a pure stimulant to the nervous system, only it acts in a more subtle way. With alcohol you see most of the effects at once, but with them it is different, for it acts like a most insidious poison. There is a certain balance in the power of the nervous system, for if it is over-stimulated it afterwards suffers from a subsequent exhaustion which we see in nervous irritability, atonic dyspepsia, neuralgia, decayed teeth, consti-

* A blatant falsehood.—Ed. T. A.

adulthood. Having given some of the evil effects of them, it is only right that I should give some of its good effects. Therein has developed the brain power of our race, as is seen in the wonderful advance of inventive power. It has raised the animal man into the brain man. The crave for education is a consequence of a stimulating power developing the brain, but the question is whether this sudden forcing ahead of man's nervous system is for his permanent advantage. Is the Australian, who heads the list of nations who drink tea, which nature has compelled him to do in consequence of the large quantity of meat he eats, gaining by this hothouse forcing of his nervous system in a hot climate like ours? I say certainly not, for of all Australian vices I look on the one which is most likely to permanently injure his constitution, or rather the constitutions of his children, is his tea-drinking habits. My answer, then, to this question—Is teetotalism as now carried out, advantageous to the human race? must be in the negative, for with the non-abstainers who drink tea largely the alcohol they take in a measure counteracts the injurious effects of them.*

The doctor contends that "we should not less meat and more vegetables, especially fruit, and then we should not require the amount of stimulants now consumed by the teetotal and non-teetotal members of the community, and the future race will have a better prospect before it, for there are already signs of degeneration in our race. The degeneration of a race commences with its female members, in that at first they cannot nourish their little ones, and then they have very small families. The first of these failings we notice amongst us. Woman's brains are being stimulated too much by them, consequently she may become highly developed at the expense of her usefulness. In conclusion I am of opinion that teetotalism as at present carried on is useless for State purposes, for I consider that a race of people imbibing tea largely without fermented beverages would suffer the same fate as some of the vegetarian colonies, for it might answer with the parents but it would be death to their children. The race would wear out owing to nerve exhaustion. The above are the thoughts of one who has been an almost lifelong teetotaler. Tea, coffee, cocoa, tobacco, fermented drinks have all their usefulness, and when taken in moderation may not do harm any more than meat, vegetables and fruit. But they must be taken in reason, and then they are not harmful. Virtue carried to excess becomes irksome to others, and so it is with all things. Tea plays havoc with our food ferments—nature's guardians of our bodies against disease. We live in an age of stimulants—an age of excitement—and we demand impossibilities. We have discovered a few things and get disgusted at not knowing all things. We expect the microscope to tell us everything about the causes of disease, yet are too lazy to analyse the blood during the different stages of disease, but listen with mouth wide open to everyone who says he has discovered the cause of this or that disease, when in reality no single microbe has been so far proved to cause any one disease. Pasteur, the chemist, is the only man who has told us anything positive, and the chemist we must depend on, at least so says my brother, Heneage Gibbs, in his latest work on 'Morbid Histology', just published. The Russians place a slice of lemon in their tea, which must strengthen its power of delaying the digestion of food, and in the Black country the men add salt to their beer. Tea is poison to anyone with a consumptive tendency."—*Sydney Daily Telegraph*, Feb. 20th.

CULTURE OF INDIARUBBER TREES.

Mr. H. Crist, of Bale, Switzerland, writing on the above subject in *Garden and Forest*, says:—It is, perhaps, worth while to call attention to the ease with which that beautiful tree can be propagated by cuttings. As is well known, it is only necessary to take a piece of a branch and insert it into moist sand,

and to protect the cutting with a bell-glass to secure a rooted plant; but it is less well-known, perhaps, that the last articulation of the branch is capable of making roots much more quickly and readily than those lower down. Mr. Gamble, inspector of the forests of Madras, in South India, tells me that when they desire, in his district, to make plantations of this valuable tree, workmen always take the end of a branch with a single leaf for the cutting, as experience has shown that this is the way to obtain plants quickly and surely, and I believe that horticulturists would do well to follow this plan always in propagating *Ficus elastica*.

This tree, by the way, does not demand a real tropical climate. On the contrary, it flourishes outside the tropics in regions where snow falls sometimes and which experience several degrees of frost. I have seen in the beautiful garden of Hamah, near Algiers, specimens of *Ficus elastica*, and of its relative, *F. Roburghii*, as large as our large forest trees, casting a shade blacker and thicker than I have ever seen before. Generally, the genus *Ficus* is hardy and easy to acclimatise.

Ficus australis succeeds admirably in Algiers, and *F. Benjaminia* is used in the same city as a shade tree in the suburb of Mustapba. There is a large specimen of *Ficus australis*, already old, on the Italian Riviera at Mentone, which, protected on the north by a house, forms a superb mass of dark green foliage; and at Cadiz there is a handsome avenue of large fig-trees, with small leaves, not far from the Botanic Garden. These are trees two feet or more in diameter of trunk, with thick spreading heads. There are often severe frosts, however, in all these regions.

With regard to the fruit of *Ficus elastica*, I have once seen it on a small plant cultivated in a pot at Baló, so that it appears that this species bears fruit sometimes in a comparatively young state.—*India-Rubber Journal*.

THE ORIGIN OF PETROLEUM.

Theories as to the origin of petroleum have been numerous—some plausible, some hardly so, but ingenious, some ridiculous, though all more or less interesting as presented by their advocates, the following rather unique theory is propounded by T. E. Malone in the *Pittsburgh Dispatch*:—

What was the origin of the oil that exists in the earth in such vast quantities? This is the question that the thoughtful observer asks himself as he surveys a score or more of immense wells at McDougal, out of which in the aggregate fully 80,000 barrels of oil are discharged daily. Think of it—a vast river of petroleum rushing out of the earth. Truly this question is one that is sufficient to set us to thinking. How are we to account for this obnoxious wonder that comes up from 1,600 ft. or more below the level of the hills? How easy for some to put the question off with the remark that it is not for us to answer—that it is one of the mysteries of the world that God did not intend that man should ever understand; but the thinker is not to be satisfied with any such evasion of a question the nature of which demands an explanation.

Down deep in the earth he knows that there is a vast deposit of oil. Call it lake, or river, or what you will, it is there, and, judging from the amount that rushes up through a 6 in. casing in a second of time, one is inclined to think that it is very tired of imprisonment, and has long been wanting to get out.

The scientific man, ever ready to wrestle with any vexatious problem, is the only individual that undertakes to give us any light on the subject. He admits that it is a profound subject in every sense of the word, and wishes that he had some kind of a subterranean telescope that would enable him to study the rocks from whence this great volume of petroleum comes as the astronomers study the stars. The distance that intervenes shuts out an investigation as completely as if the source of the oil was far beyond the North Pole.

But the drill and the sand pump that go down into the earth, what do they reveal? Look at the

* Fancy a man daring to talk of alcohol counteracting the effects of teine!—*Kd. T. A.*

sand and pebbles that are brought up just before the oil is struck, and what do they indicate? Solid rock. Yes, rocks such as are exposed in railway cuts and quarries, and which in such places are found to be devoid of oil as any other thing, unless it be a few fossil plants or shells.

These surface rocks are not to be compared to those oil-producing sand rocks, for we are positive that the latter are as full of oil as a sponge thrown into a river is of water. They are, indeed, so full of petroleum that it acts as a barrier against a tremendous pressure of natural gas, and it is this pressure that lifts a solid column of oil 6 in. in diameter and 1,700 ft. or more in height, together with thousands of pounds of steel tools, out of the casing with apparently no effort.

To be plain, and to avoid bewildering technicalities, we will state that, so far as chemistry has been able to ascertain, the oil appears to be of animal and vegetable origin. There are exceptions to this finding of chemistry, of course, and theories that deal with the spontaneous generation of petroleum from other sources are common and some of them are very plausible, but we believe that we are justified in asserting that the majority of scientists are of the opinion that this petroleum had its origin in the abundant fauna and flora of prehistoric geological ages.

In connection with this statement, allow me to say that this word prehistoric is not a fit term to use in referring to the fauna and flora of the Devonian age. In speaking of some old mines that may be seen on the earth's surface, such as the walls of Casa Grande on the Gila desert, or the ruins of Yucatan, we may with propriety use the word, but in speaking of the remote geological ages it has no bearing whatever, and is out of place. Are we, then, to understand that this oil was produced from the remains of ancient animal and vegetable life. Is it possible to conceive of the necessary materials in such enormous quantities as would justify such a belief?

In the vast deposits of the upper and lower silurian formations there are more than 10,000 ft. of limestone made entirely of molasses. These immense beds of limestone are of vast extent, and everywhere they are amazingly fossiliferous. Take 400,000 square miles of limestone 10,000 ft. in thickness, and entirely made up of the remains of animal life; add to this a similar extent of Devonian formations crowded with the remains of fishes, molasses, and crustaceans, and then add to that 8,000 ft. or more of carboniferous matter, packed with the abundant remains of a tropical vegetation, and what have you got?

It is easy to conceive of an ocean of oil coming from all these things, providing they were well squeezed like apples in some immense cider press and the juices preserved. And what better evidence of a pressure sufficient to accomplish this is wanted than that which is obtained by studying the gigantic upheavals and inward lateral crushing convulsions that are suggested by the Appalachian and Rocky Mountain ranges.

Here, then, were the materials and there were the forces sufficient to account for this immense deposit of oil that has been released by artificial perforation of the rocks at McDonald and other places.

To come a little nearer home in an effort to show the enormous quantity of vegetable matter that must have been buried by inundation and subsequent elevations of the surface of the earth, let us go to Mansfield, nine miles from Pittsburg, on the Pan Handle, where, in cutting down an immense hill, the workmen have discovered a vast and wonderful deposit of fossil plants.

There, packed in the solid blue and black shales, are the abundant remains of the vegetation of the carboniferous age. Perfect casts of beautiful arborescent ferns and calamities, rushes of gigantic length, and curiously carved trunks of the lepidodendron and sigillaria are all heaped and pent in one inseparable mass. Even the unlearned Italian labourers are amazed at the sight. On every block of shale are a thousand perfect casts of plants and a

hundred different varieties. There are enough specimens here to stock a million cabinets. A road, bed for the third track of the Pittsburg, Cincinnati Chicago and St. Louis railroad is being graded with remains of one of the forests of the ancient world. Look where you will, go where you will in the vicinity of this cut, and everywhere you tread upon the perfect casts of plants that grew in some old carboniferous lagoon, perhaps 10,000,000 years ago.

Here then, probably, was the origin of our great deposits of coal, and it may, in conjunction with the other fossils above mentioned, have helped to produce the vast supplies of "golden ile" in the form of petroleum.—*Chemical Trade Journal*.

Two of the largest sugar-houses at Greenock are about to suspend melting operations temporarily, in consequence, it is said, of the high prices of raw sugar, which, it is stated, does not allow of refining at a profit. The firms in question have recently been paying off workers.—*A. F. Press*.

WATTLE BARK.—An influential company, consisting of well known Rand and Pretoria men, is in course of formation for the purpose of prosecuting the wattle bark industry in the Transvaal. Land has been selected in one of the best districts in the sister republic, and an old Natalian will pilot the venture. It is stated by experts that owing to the chemicals in the soil the bark grown in the republic will yield about three per cent more of tannic acid than the tree in Natal. The scheme is to be started on a gigantic scale.—*Witness*.

QUININE AS A PROPHYLACTIC.—Mr. Rhodes, the Prime Minister of Cape Colony, reports that during his journey to Mashonaland he took plenty of quinine in order to resist the malarial fever. Thanks to this, he and his party got through the wilds without any of his party being laid up with fever, for, although they felt feverish occasionally they exceeded in warding off the affection. Mr. Rhodes's experience confirms the published experiences of Dr. Binz, Dr. Graesser, Dr. Buwalda, Dr. O. Schelling, Dr. Tschirch and other authorities who have travelled in the tropics that quinine guards against and effectually prevents malarial fever.—*Chemist and Druggist*.

SWEET POMELOS.—Mr. G. I. B., in a late number, asks information about grape fruits and how to protect pineapples. I lately had an opportunity of sampling the fruit of the sweet pomelo, to which you refer, and think so highly of it that I would urge G. I. B. not to plant any other. This pomelo originated in this vicinity and seems a cross between the common pomelo and the orange. It is somewhat smaller than the common variety, the peel thinner and there seems an entire absence of the bitter taste which is found in the inner peel of the ordinary pomelo. The flavor is very fine, being a combination of both orange and pomelo. It is liked at once and can be eaten out of hand like an orange, as it requires no sugar. I do not know where trees of this variety can be obtained at present, but understand they are being budded by nurserymen and trees will doubtless soon be offered on the market.—*Farmer and Fruit-Grower*.

It is by no means a new idea that the prairies of the Far West are practically treeless owing to the extensive fires that devastate them after the grass withers; but Mr. Miller Christy, F.R.S., has brought forward a large amount of evidence in favour of it. The most promising of other theories is to the effect that the prairies are the beds of large lakes, the black mould being the sediment or mud. Mr. Christy regards the black mould as the ash of the repeated fires. Formerly the Indians used to burn the prairies in the fall, leaving patches for the buffalo to feed on. Now they are burned by the settlers in the spring or by accidental ignition from neglect, or out of wantonness. Whatever be the correct theory, it is certain that trees will grow on the prairie lands where they are protected, as around homesteads, or by the banks of rivers. There seems to be nothing in the soil itself which forbids the growth of timber.—*Globe*.

A GERMAN PROFESSOR ON INDIAN DRUG-CULTURE.

About three years ago Dr. Alexander Tschirch, then a "Privatdozent," or University coach, in Berlin, and already well known as an authority on pharmacological and botanical subjects, undertook a voyage to the British and Dutch colonies in the East with the chief object of gathering on the spot information concerning those economic plants, the products of which represent the bulk of the value of the whole Eastern trade. After his return to Europe Dr. Tschirch published several short notes on his Indian experiences, abstracts of which we have upon several occasions placed before our readers. It was also announced that the doctor (who has since become professor at Berne University) was busy upon the regulation book of travels, the production of which is as integral a part of well-conducted modern travel as the process of rumination is essential to the digestive functions of a well-conditioned member of the ovino family. The doctor's book has been long in making its appearance, but it has come at last, and we hail it with satisfaction as a welcome contribution to the historiography of Indian economic plants. The professor on his travels has preserved an open mind, and he shows himself in his book remarkably and pleasantly free from the dogmatic assertion of superiority, which is often so aggressive a feature of books written by scientists upon general subjects. To describe in full detail and from personal observation all, or even the majority of Indian economic plants, would be the task of a lifetime. It is being accomplished by scientists in British India; but Dr. Tschirch does not pretend to have accomplished anything of the kind during his limited sojourn in the tropics. He claims for his book no further value than it actually does possess—that is, as an account of a trained botanist and pharmacologist in his visits to the principal producing centres of some tropical products—many of them staple articles of commerce, such as cinchona, coffee, tea, cocoa, rice, cloves, nutmegs, and mace, rubber and pepper; others, articles of much less money value, but not on that account less interesting to the pharmacist—benzoin, for instance, cubebs, cardamoms, citronella oil, and cinamon. Dr. Tschirch, himself expresses his regret that circumstances prevented him from investigating, as he had wished to do, the culture of tobacco in Sumatra, and that of indigo and sugar in Java. Malarial fever, that most faithful travelling companion of the European in tropical travel, seldom permitted the author to work as he would have wished. Another obstacle to the acquisition of reliable information lay in the ignorance which prevails, especially in Java, concerning all cultures in which the informant is not personally interested. Cubebs, for instance, are much grown in the residency of Bantam, in western Java; but although Dr. Tschirch tried as much as he could to get accurate information about the culture of this drug during his sojourn in the adjoining residency, or province, no one could tell him anything trustworthy about it, and Bantam itself he had no opportunity of visiting. Steadfastly adhering to the sound principle of describing only what he actually saw, the doctor has rigidly excluded all hearsay information from his book—a resolve which must often have been a painful one to him, though it has rendered his book much more reliable.

Dr. Tschirch, who, be it observed, as a German-Swiss, travelled without any prejudices in favour of one of the two great colonising Powers of the East, the British and the Dutch, thus sums up a difference in the planting and trading habits of the two nations which struck him most strongly all through his travels:—"Both nations work with the same object of utilising their colonies to the greatest advantage, but they attain this object in very different ways, and they work on totally different principles. If we glance through the export lists of the three principal ports of the Southern East—Columbo, Singapore, and Batavia—our attention is immediately attracted by the stolid

steadiness of the Dutch, and the almost lightning rapidity of the changeableness of the English colonial modes of cultivation. While the Dutchman sticks with extreme stubbornness to the cultivation of any culture he has once introduced, and only relinquishes it with evident pain and under incessant doubting of heart, the Englishman no sooner begins to feel doubts of the success of his undertaking than he is prepared to relinquish it immediately. Thus, to give an instance, the market variations and the ever-sinking price of quinine have not been able to deter the Hollanders from continuing to plant cinchona in Java upon a scale increasing year by year. The action of the English in Ceylon is the precise opposite of this mode of procedure.* The first shipments of Ceylon coffee are sent to London, and fetch high prices. Immediately an exodus of Anglo-Indian planters to Ceylon commences; everybody wants to grow coffee and does grow it. Result: a 'rush into coffee,' with scamped and careless methods of cultivation; † then a coffee-disease declares itself. Planter after planter 'cracks up,' and when it is also found that the formerly despised cinchona culture, into which, without much ceremony, everyone has straightway thrown himself, will not prosper as it was expected, tea is taken up after short deliberation. What the *Hemilea* has left standing of cinchona and coffee plantations is uprooted, and replaced by tea on such a colossal scale that the tea export rises between 1877 and 1887 from 3,500 lb. to 22,000,000 lb. ! Needless to say such haste precludes the careful selection of soil and situation; nor is it possible to weed the forest ground carefully. ‡ This is the reason that every visitor notices at once an essential difference between the plantations in the two islands. In Ceylon rotting tree-trunks and numberless stumps all through the plantation, in Java everything neat and clean; the lines more carefully drawn, nowhere remains of trees or stumps." The superior energy of the Englishman Dr. Tschirch illustrates by calling attention to our occupation of Singapore, the entrance-gate to Eastern Asia, and to the commercial life-and-death struggle between that port and Batavia. Singapore, in spite of its faults as a harbor, attracts every year more products from the Malay Archipelago. It is already the most important emporium in the world for pepper and gambier, and draws growing supplies of rubber and gutta-percha, damar gum and nutmegs, benzoin and rattans. Just as the harbor of Batavia slowly becomes choked with sand and retreats further and further from the town, so the export trade of Batavia runs to sand, choked by the powerful competition of Singapore.

But though Singapore is very favorably situated, the author considers that if a European Power would seize the little island of Pulu Way and its two small sister islands just at the north coast of Sumatra, at the opening of the Straits of Malacca, and create a good harbour there, Singapore would be doomed in its turn. Pulu Way has immense coal-mines, and Dr. Tschirch, who is a colonial enthusiast, calls upon Germany to seize the group and lead the way. Unfortunately for him, his desire is not likely to be gratified. The German Government has had enough of colonial enterprises at present, and recent information from the Dutch Indies states that the Netherlands Government have decided to occupy Pulu Way, and explore its coal-mines and that the French and Russian Governments have already promised the custom of their mail-steamers to the coaling-station. Singapore, therefore, may again take heart of grace. Who is saved for the present.—*Chemist and Druggist.*

* For the good reason that the Dutch are in a position to supply the world with the best species.—*Ed. T. A.*

† An utterly unfounded charge.—*Ed. T. A.*

‡ There are no plantations in the world better wooded than those of Ceylon, although the half-burnt forest trees are left on the ground to supply fuel and manure.—*Ed. T. A.*

THE QUESTION OF AGRICULTURAL BANKS.

A year has elapsed since we published the last of a series of articles on "Poplar Banks for India." In those articles it was our object to show that in all countries farming must be assisted by credit, especially for all permanent improvements. Even in England and Scotland (where the landlord's capital finds the land, buildings and improvements), loans from the Treasury, from private Banks and other sources are necessary for the development of agriculture; while in France, Germany, Italy, Austria and Russia the peasant-farmers, whether from the vicissitudes of climate, from the laws of inheritance, from the weight of taxation and rentals, from the smallness of the farms, from misfortunes such as disease of cattle and crops, or from other causes, are generally dependent on borrowed capital even for current operations, and are seldom able to make permanent improvements by means of their own capital. To this common lot of peasant farmers the Indian ryot is no exception. We showed in those articles that wherever a proper system of banking has not been introduced, the peasant farmers are universally fleeced by the money-lender, or "exposed to the excesses of the most unbridled usury," as in Italy, and that the progress of agriculture is checked. We explained that wherever Poplar Banks have been introduced they have cut down usurious interest, bridled the money-lender, created and strengthened habits of saving of business, of co-operation, and of mutual confidence, and are distributing hoarded and barren capital in immense sums—probably above £100,000,000 per annum in Germany, £50,000,000 in Italy, where they are of very recent origin—to those who have need of it, but to whom it was hitherto inaccessible. We showed how these Banks were invented and started, both in Germany and Italy, by the efforts of individuals, who saw what was needed, instead of by the people themselves, who could not start them for lack of enterprise, knowledge, and confidence. We proved that the efforts of the promoters were justified by the results, thus showing that a popular reform, however necessary and however possible by the conditions of society, is not invariably indicated beforehand by any popular movement or expression, but may be brought about by extraneous action. Further, we showed that these Banks can be originated by half-a-dozen men, with but very small personal capital, provided they are men of integrity and piudence. We pointed out that the principles of the Banks are self-help with mutual guarantees; that that security provided by the moral and material guarantees of the Association enables capital to be obtained on reasonable terms; and that this capital lent prudently on short terms, and in small loans to members of the Association, yields reasonable profit to the Association, and inestimable benefit to the individual borrowers. Finally, we contended that the Banks of this description are suited to all classes of industrial employment in which capital is required for short terms, and that agriculturists needing short loans are on even better terms than other borrowers, since they have material security to offer, but that when loans are need for long terms, as for permanent improvements special arrangements are necessary such as the *Buoni di Tesoro dell' Agricoltura* of Italy.

Although we can point to no substantial marks of progress towards the attainment of the object specified in the articles to which we have been referring we are satisfied that some advance has been made. Mr. F. A. Nicholson during the ten months' sick leave from which he has just returned has been investigating the systems of Agricultural and Poplar Banks in vogue in Europe. He has collected a mass of facts and figures, and has made himself acquainted with the latest developments in the systems of those two countries; and we now understand that Lord Wenlock's Government has decided to place him on special duty with a view to his making a digest of the stores of information, that he has accumulated and reporting how far the Continental systems would be applicable

to this country. Of course Poplar Banks by themselves are not capable of dealing with all the demands of landed proprietors. They can deal only with loans required for daily and seasonal wants and with those which are repayable within two or three years at most; they cannot fully satisfy those wants which concern the permanent improvement of land. These require not only a large amount of capital, but a very long period for gradual repayment. In fact the whole question has to be dealt with in a larger way and on broader lines than those indicated in the articles published in these columns, in which that side of credit commonly called "personal" credit was chiefly handled. Mr. Nicholson in studying the subject has been brought into contact with the Land Banks, the *Credit Foncier* of France and the *Landchaften* of Germany, and has been to some extent able to ascertain how far they are able to deal with the demands for capital of the agriculturists of Europe. His special work will involve not merely a consideration of what is being done in this direction in other countries, but a larger knowledge of the conditions of this country and a very careful application of what has been found possible in Europe to the conditions as found in India, with, at the same time, a comparative study of the laws of other countries with a view to such legislation as may hereafter be found necessary for adapting such Banks to the wants of rural India. The question of legislation is of course a very difficult one. Even on the Continent, where these Banks have been not only under discussion but in working order for over 40 or 50 years, continual legislation is found necessary, legislation to improve and assist the new forms of Association and legislation to correct the previous faulty enactments. Probably, however it is in the social conditions of this country that the greatest difficulties will be found. However perfect a scheme it cannot but fail if the men who must work it are found wanting, while, on the other hand, even an imperfect system will meet with eventual success by the gradual elimination of errors and imperfections, if only there be found in India business-like social reformers such as have made credit on reasonable terms a possibility and a fact in Europe even for the smallest farmer, and the most usury-ridden community; men of action as well as men of speech; men in whom a beneficent philanthropy was added to the most successful business capacity. If these men are found in India—and why should they not be?—then it will be easy for credit to become really "popular," upon the basis of a true banking system, and to relegate the old-fashioned money lender with his elementary methods of rural finance to his proper position.—*M. Mail.*

NEW NITRATE FIELDS.

Nitrate of soda, besides being a most important factor in chemistry—it is converted into saltpetre, and is extensively used in the manufacture of ammunition, &c.—is one of the most highly concentrated of nitrogenous fertilizers, and is the more valuable for the reason that the nitrogen is not dissipated by exposure to the atmosphere. The remarkable development during the past few years of the nitrate industry of Chili, where the hitherto only known deposits of caliche (the crude material) exist, has directed attention to the possibility of finding the mineral in other quarters of the globe. The origin of nitrate has given rise to various conjectures but most geologists seem to favour the theory of its formation by a peculiar deposit, partly organic, partly inorganic, left by the sea on receding from the land in prehistoric times. Nitrate, being readily soluble in water, the area where it may be sought with any degree of success is necessarily circumscribed; the principal rainfall regions, in addition to the Pacific slopes of the Andes in South America, comprising vast arid territories in Northern India under the shadow of the Himalayas, and the desert plains of Central Africa. It has been stated that the caliche-forming process is now proceeding on the Western Coast of the African

Continent, in the same latitude as the deposits occur in Chili, but the physical difficulties the country presents have, so far, prevented a complete survey.

THE DISCOVERY.

Speko and Grant (whose distinguished services were by the way, ill requited by their country) in their travels in Central Africa, twenty-five years ago, made allusion to extensive fields of natural "sodium" which the natives on the shores of Lake Tanganyika collected and bartered with the neighbouring tribes, whilst earlier in the century the famous and amiable Dr. Moffat, referring to a saline deposit in that *terra incognita*, described it as "saltpetre." But within the last fortnight more concise and authentic information has been received, and the existence of practically inexhaustible beds of nitrate in the Equatorial provinces is reported on the authority of the German explorer, Dr. Peters. This important discovery has been made within the German sphere of influence, but there is strong presumptive evidence that similar deposits will be found within the adjoining territory of the British East African Company, where the climatic and geological conditions are almost precisely identical. Owing to the difficulty of transport a few years must elapse before African nitrate can become a merchantable commodity, but the partition of Africa amongst the European powers has been followed by extraordinarily rapid developments, and railroad communication with the interior is simply a question of time. Already the subject of constructing a railway to the great lakes is under consideration, and in support of the project the Government this week are bringing forward a proposal to grant £20,000 towards the survey of a line from Mombasa (Zanzibar) to the Victoria Nyanza.—*Liverpool Monthly Circular*.

TRADE PROSPECTS IN CENTRAL AFRICA.

Before a special general meeting of the London Chamber of Commerce, held in the council-room, Bazaar-house, Eastcheap, a paper was read on Thursday by Mr. Montague Jephson on "The Possible Expansion of British Trade in East Africa." Sir A. K. Rollit, M.P., Chairman of the Council, presided, and there was a good attendance.

Mr. JEPHSON observed that three-quarters of the British public thought that Central Africa was either one huge desert or one huge forest, but in the interior of the country there were vast tracts of fertile land, which were only awaiting cultivation to yield a practically unlimited supply of raw material to feed our British looms and factories, and there was also a vast negro population ready to exchange our manufactured goods for those raw products. It was impossible entirely to separate trade and philanthropy in Africa. Any one reading the history of the march of civilization in Africa must be struck by the fact that most of the important and lasting benefits to civilization in Central Africa were due to trade. The British East Africa Company was largely composed of Scotch and English gentlemen, whose philanthropic instincts were as proverbial as their instincts for business and commerce. He considered Uganda, owing to its position, to its commanding so extended a waterway, and to the healthiness of the climate, as the key to the rich countries of the interior. Ivory travellers who had visited Uganda invariably spoke of it as a country with a great future. Very superior coffee grew there wild in abundance, and, if cultivated, it would become a great source of wealth and revenue to the country. They might safely consider that tea was another trade which would spring up with the pacification and development of Uganda. It has also been for many years a great up-country depot for ivory. In all the upland countries lying around the head-waters of the Nile cattle were plentiful, and a large trade in hides could also be organized. One of the chief sources through which Emin had proposed to bring in a large revenue for the province was oil. The raw cotton which might be imported from Africa into England if the cultivation of the cotton plant were properly developed would free England entirely from

being dependent upon foreign countries for her raw cotton, much of which could be returned to Africa in the shape of manufactured cotton cloth. Almost the entire country between the lakes and the coast was suitable for the cultivation of cotton. The growing of tobacco, too, might be developed into a large trade. Sugar-cane, wild indigo, and fibre plants grew freely and were indigenous in many parts of Africa within the British sphere of influence. Cereals of many kinds, as well as rice and oil seeds, could be grown greatly in excess of home requirements, and could be exported to India, the Red Sea and the Persian Gulf. In fact, there were few necessary things which could not be grown in the British sphere of influence in Africa. One of the most important of the many natural products of Equatorial Africa was indiarubber, and the trade in ostrich feathers was capable of great extension. Although there were in Central Africa many million acres of rolling grass downs, all these savannahs were so infested with parasites that sheep would not, he thought, become sufficiently numerous to make Africa a wool-producing country. Throughout the whole of Central Africa there was abundance of iron ore, and gold-bearing quartz had been found in large quantity. Copper knives and ornaments were common features in Mombasa, Niarniam and the adjoining countries, where the metal was found in large deposits.

Speaking of the probable imports of manufactured goods from Great Britain, the lecturer said that between Mombasa and the Victoria Nyanza the usual Manchester cotton goods, woollen stuff, beads of various kinds, brass and iron wire and iron boxes, and hardware of all kinds were the mutual coin of the country. He hoped that as trade developed in Africa, and as the means of transport were improved, the manufactured goods we introduced would be of a better quality. It was, however, useless to talk about extending trade in Africa and bringing up trade goods to a better description without having railways to transport them. Stanley, as far back as the time when he first entered Africa on his search for Livingstone, said that nothing would ever be done in Africa until it was surrounded by an iron girdle. What was now wanted was to produce a storm of public feeling so overwhelming that no Government would dare to ignore public opinion by refusing measures for granting a guarantee necessary to enable a company to build a railway from the coast to Lake Victoria. Its construction should be considered as belonging to the duty of the Imperial Government, for it would be the means of stamping out the slave trade and opening up British East Africa to civilization and commerce, which was eminently an Imperial duty. At present everything in Africa had to be carried on men's heads, and therefore the Arabs made slave raids to obtain slaves, whom they used as beasts of burden. If the railway were built and steamers put upon the lake there would be no longer any need for human carriers. He would impress strongly upon their minds that this help which was expected from the Government was not a party affair, and that the scheme of a railway was entirely suggested by the declarations embodied in the Brussels Act, and the necessity there was for opening up new fields for British manufactures. The Government was not asked to put a further burden upon the Treasury, but merely to turn a portion of the £200,000 which it annually expended upon its squadron on the East Coast into another and much more effective channel. He thought he was not unreasonable in asking the various Chambers of Commerce to use their influence with the Government, to make sure that what the Government had recognized as its duty at the Brussels Conference should be carried out.—*London Times*, March 5.

CINCHONA PROSPECTS.

Where no counsel is, the people fall; but in the multitude of counsellors there is safety. When, about three thousand years ago, Solomon laid down this opinion it is evident that he did not foresee the plan upon which the speculative produce business in general and the quinine trade in particular, would be conducted at the end of the nineteenth century. The very largeness

of the multitude of counsellors and prophets anxious to serve as guides to the would-be investor renders it exceedingly difficult for that over-protected individual to judge the merits of each one, especially as the advisers seldom agree in their opinions, or even in their facts. A remarkable instance of this want of agreement is shown in three expressions of opinion on the prospective supply of cinchona which reach us almost simultaneously from different sources. The writers are all practical planters and anxious, apparently, to state what they conceive to be truth. One, Baron v. Rosenberg, of Devicolom, Madras, addresses the editor of this journal; another, Mr. Anton Kessler, of Garoot, Java, writes to a planter friend in Ceylon, who has handed the letter to the "Ceylon Times;" and the last, Mr. Winning, a well-known Dutch-Indian cinchona authority, contributes an article to a review published in Java. These three authorities, each, it would seem unaware of the other's intentions, were moved to write their impressions about six weeks ago. Mr. Winning, among a number of other statements, opines that in 1892 Java will ship 3,300,000 kilos.; in 1893, 3,500,000 kilos.; and in 1894, 3,800,000 kilos. of bark—the highest of these figures being below her shipments of 1891; and he proceeds to build up elaborate calculations upon the assumption that the average quinine percentage of the Java bark will remain stationary at 4 per cent. Continuing his argument upon these lines, Mr. Winning comes to the conclusion that we are at this moment faced by an output of quinine insufficient for the world's requirements, his estimate of the total quinine production from all sources being:—For 1892, 226,500 kilos.; for 1893, 225,500 kilos.; and for 1894, 228,500 kilos. Mr. Winning's figures have been promptly seized by quinine manufacturers and others for commercial purposes; and it is to be hoped, for the sake of those who may become victims to their allurements, that they will pan out aright.

Then comes Baron v. Rosenberg, who, in the letter to which we have referred, takes credit, more in sorrow than in anger, for having prophesied truth four years ago, though his truths were of such evil purport that no one would listen to them. The Dutchman, Mr. Kessler, too, lifts his voice as an unappreciated Cassandra. Listen to his admonitions to his planting friend in Ceylon:—

"You have left cinchona and run across to tea. I think you were right, for cinchona is looking very like a wreck, and may prove one even if Java be left alone with it. You may recollect that I prophesied in 1887 what we are now experiencing. Your people did not believe me, and some of them may have thought I was "doing them." But I know I was not and advised your people to root up their cinchona when the unit was at 4; they must now own that I gave them good advice."

"And what will the future be? Our bark in Java average now from 4 to 4½ per cent, and will average about twice as much some years hence, for we are doing our best to cultivate high-class barks. We export 6½ million kilos now, and will go on increasing; you may calculate for yourself what this means. Very little is heard of estates that will be abandoned, though there are some, and most estates cannot cultivate any other produce well on account of their situation, the restrictions of their lease, or because their shareholders do not care to embark into something new which might swallow more money in case of failure. So most people stick to the old thing in hopes of killing out their weaker neighbours or that better times may come. I myself doubted of their early advent, and rooted up 300 acres, which is now under coffee."

So far Mr. Kessler. It will be seen at once that he and Mr. Winning cannot both be correct, and Baron v. Rosenberg is more or less at issue with the two. One comfort is that, though utterly at variance as regards the future, "I told you so," is the harmonious burden of their songs where they treat of the past.

Baron v. Rosenberg thinks that a large proportion of the Java bark is below the paying point of richness, and he infers that the poorer plantations in the

island must be in process of uprooting if they have not already ceased to exist. Upon this point Mr. Kessler contradicts him flatly, and even goes so far as to assert, that in a few years Java bark will average 8 to 9 per cent. of quinine, while the quantity shipped, weight for weight, will go on increasing also. This statement is in accord with the reports from our Amsterdam correspondent which we published over four years ago. While we are calling attention to the various disciples of Old Moore who are raising their voices at this moment, it may not be out of place to recall the fact that we too, in a modest way, have occasionally ventured upon a bit of horoscope-casting. On December 17th, 1887, we wrote, in commenting upon the statement of our Amsterdam correspondent that orders for the planting of 300,000 exceptionally rich trees had been sent to Java:—

"It is quite possible that within a couple of years Java will absolutely dominate the cinchona market...Ceylon planters will do well, therefore, to ask themselves seriously whether they have any prospect of holding their own against such competition as.. is looming near at hand."

But to return to the three "planting prophets." Baron v. Rosenberg, when recently in Ceylon, was assured that if ivory tree in that island were uprooted perhaps 3,000,000 lb. of bark might be cropped, with which the production would be finished entirely. If that statement be true, all the Ceylon authorities and most of the leading London importers and brokers are hopelessly at sea in their estimates.

Baron v. Rosenberg believes that Ceylon and India "will both again decrease their shipments this year." So far as India is concerned, that view also is not accepted by the leading representatives of the cinchona industry in London, though probably our correspondent, who is an Indian planter himself, has better means of judging on this point than there.

In the face of all these contradictory opinions the wisest course would seem to be—let the future take care of itself; but that is a course which will certainly not be received with approbation by the large majority of those who spend a great part of their days in calculating, from imperfect data, the chances of a rise or fall in the quinine market.

Prophete recte, Prophete links
Das Weltkind in der Mitten,
says Goethe. The unfortunate world-child who happens to be financially interested in bark or quinine is tormented by the doubt which of the rival prophets he shall follow; and, needless to say, his choice falls, in almost every case, upon the one whose views coincide most nearly with his own hopes of gain. Though no one can compute even approximately the sum total of brain-power spent upon vain calculations of what the future holds in its lap, two things are tolerably certain: first, that the energy mispent upon such calculations, if directed to the solution of any problem likely to advance the interests of mankind, would bring lasting renown to the mathematicians cogaged in it; secondly, that if, peradventure, the hopes and estimates of any speculator should be realised to the full, that individual, instead of preparing to enjoy at ease the fruits of his foresight, will immediately commence to worry his soul afresh, and to destroy the remnants of his digestive organs with a new set of calculations about what is to happen five or six years further ahead, and risk his money upon the realisation of that fresh set of calculations.—*Chemist and Druggist*, Feb. 20th.

MORE FACTS ABOUT PRECIOUS STONES.

The following is from the *American Exporter*. We seem to have missed the first article referred to, but it will probably turn up:—

Last month we considered briefly the constitution and value of the four leading ornamental gems, viz., the diamond, the ruby, the sapphire and the emerald; and we noticed in passing, also, a few stones of the chrysoberyl family, allied to the emerald or beryl group.

We have now to consider the subordinate gems, of the second and third classes, and first let us con-

merate a few of the best specimens derived chiefly from the materials known as alumina and silica. Of these the turquoise is perhaps the most prominent, and certainly one of most popular. The turquoise consists of about two parts alumina, one part phosphoric acid and one part water. The best color is a deep sky-blue, though it is found in various shades of blue. It is one of the few precious stones which are not transparent. The finest specimens come from Persia, and inferior specimens from many other places.

The topaz, another favorite jewel of the second order, is found in two or three different varieties. The original oriental topaz of the ancients, composed chiefly of alumina, was of a brilliant yellow color, and was very highly esteemed. In these later times it has become exceedingly rare, and more valuable even than the diamond. Its rarity is so great, indeed, that it has practically gone out of the market, and the ordinary topaz of modern commerce is something entirely different, and much less valuable. It is one of the silicates, and is known as the Brazilian topaz, from the country of its origin. Its color is a lovely pink, and it is produced by firing. The metal is completely covered and encompassed with sand, which is then subjected to a very high degree of heat, and after the expiration of a certain time it is allowed to cool off gradually, and if the process is exactly successful the stone is found to have turned to a beautiful pink color. The operation, however, is a very delicate and difficult one, and many stones, in fact the great majority of them, are ruined. The heat may have been too great, or not great enough; it may have been applied too long, or not long enough; the cooling process may have been too slow, or too quick. In either case the stone is ruined; and probably not more than one-tenth of the operations are entirely successful. This makes the Brazilian topaz not only beautiful but valuable.

The zircon, hyacinth, jacinth, or jargoon, as it is variously called, is another beautiful member of the second class of gems, which is not as widely known as it ought to be. It is remarkable as being by far the heaviest of the precious stones. Those which are called zircons are brown, violet and green; the hyacinths are red, the jacinths yellow, and the jargoons greyish-white and pure white. They are found in Ceylon, Germany, France, the United States, and many other places.

The tourmaline is remarkable for its many and varied colors and groupings of shades and colors. It is composed chiefly of alumina and silica in about equal parts. It is found in Brazil, Ceylon, Siberia, Moravia, Elba, Sweden, Burma, the Tyrol, Canada and the United States.

The opal consists of about nine parts silica and one part water. Its colors vary from chalky-white to bluish-white, from yellow to red, and kaleidoscopically from one to almost any other color. In respect to this variability of color, and a sort of mysterious opacity, the opal is unique among jewels. For some absurd reason it acquired unpopularity long ago as being "unlucky," but it is now becoming again a favorite of fashion, as it well deserves to be. The best opals are found in Hungary and Honduras, but the common varieties are found more or less generally all over the world.

The chrysolite is a beautiful stone of a greenish yellow color, composed of silica, magnesia and oxide of iron.

One of the best and most useful of the silicates is the garnet, composed of silica, alumina, and protoxide of iron. It is distributed extensively all over the world in abundance, and is therefore not very costly; but it is exceedingly beautiful, rivalling in appearance even the ruby. The predominant color is red, but it varies from a brown to almost a violet hue. Caruncle is a name applied to all garnets that are cut with a smooth rounding top.

The moonstone is a species of feldspar. It is colorless, or only slightly tinted with blue, green, yellow and red, and is beautifully transparent or translucent. The lustre is vitreous, and a brilliant pearly streak of bright light plays in it from side to side. This stone has latterly become very popu-

lar, and deservedly so. It is found chiefly in Ceylon and Switzerland, and occasionally in Bavaria, Greenland, Norway and the United States.

Lapis lazuli, the "sapphire" of the ancients, is an azure blue, and is used sometimes for purposes of ornamentation in the jewelry line, though more generally for works of larger dimensions.

There remain to be considered hereafter a number of gems of the third rank, composed chiefly of quartz.

SELECT EXTRA-TROPICAL PLANTS READILY ELIGIBLE FOR INDUSTRIAL CULTURE OR NATURALISATION.

By Baron Ferdinand von Mueller, K.C.M.G., &c. (Melbourne): Printed for the Victorian Government by C. (Troedel & Co.) Price 5s.

The eighth edition of a book, which has been translated into German and French, adapted for Indian climates, and modified for that of New South Wales, needs no recommendation. The mere mention of a *roisano* is all sufficient. A book of this character, though to a large extent a compilation, is one which demands unusual knowledge and consummate judgment on the part of the compiler. Its great success indicates that these requisitions have been met. Indeed, it is a book which should not only form part of the library of every cultivator, but one which should be on the shelves of all those in any way interested in economic botany. As a condensed encyclopædia of the latter subject, this book, within its prescribed limits, has a value for a class of readers as numerous, or more so, than those for whom it was more immediately destined. Those plants which are of special interest or value are marked by an asterisk. In all, 2,485 plants are mentioned, besides very many others, of which incidental mention only is made. In the appendices, details are given as to the temperature and rainfall in various parts of the colony of Victoria. Lists are also supplied of the genera, arranged according to the purposes for which they are used, alimentary, textile, constructive, medicinal, and so on. A systematic index is also provided, in which the genera are arranged under their respective natural orders. A list of synonyms and a geographical index follow, and these are preceded by detailed lists of plants which furnish a crop in one, two, three, or more years, as the case may be. Plants adapted for very cold or very dry regions are separately enumerated, whilst the work ends with an index of vernacular names. The mere mention of some of the contents of this volume is sufficient to justify our remarks as to its utility. But its author is not yet satisfied, nor, indeed, would he or could he ever be. Accordingly, we find him, while approaching the eighth decade of his life, hoping not, indeed, that he may see "many more editions of this work brought up to the newest standard," but that he may "perhaps still be able to publish one more edition before passing away." To this end he solicits that assistance which all who are able will cheerfully give to so valiant and indefatigable a worker as Sir Ferdinand von Mueller.—*Gardeners' Chronicle*.

[We can personally testify to the great value of this compendious book of reference.—*Ed. T. A.*]

EGG-PLANTS.

Some time ago, in passing a fruit shop in Regent Street, I saw in the window some fruits of the purple Egg-plant, *Solanum Melongena*. Of course, this is closely allied to the Tomato, but it does not appear to have taken the fancy of horticulturists; yet when cooked, it is one of the most delicious of vegetables imaginable.

As there are Apples and Apples, so there are Egg-plants and Egg-plants. The white variety is sometimes cultivated in India, but it is the least valuable, as it is rather bitter; but the purple varieties are cultivated in fields everywhere, and much used by the natives and Europeans.

The best of all kinds which I have ever tried is one grown in Delhi, under the name of Mároo Báingau. Báingau is the native generic name of this plant, but Mároo is, I suspect, a corruption of the English word marrow, as, when cooked, its pulp has a marrowy delicacy. The fruit of this grows to the size of a child's head, and is of a light purple. I do not know the origin of the word Báingau. I cannot find this plant in De Candolle's *Origin of Cultivated Plants*. It may possibly be a South American plant, originally introduced into India by the Portuguese. The French call it Aubergine, and also Melongene; the Italians call it Melongiana; and the English in India often call it Brinjal. All these words, with the specific Latin name, Melongena, evidently have one derivation; and the Indian name, Báingau makes one suspect that it is a further corruption of the same name.* In India, among dyers, the word Baingni has been adopted to indicate a purplish shade of colour, so probably the cultivation of the plant is of old date.

As the French are fond of Aubergines, they should note in Delhi are to be procured the seeds of a very fine variety. It is never certain, however, that a good variety in one place will maintain its fine character when grown elsewhere. Tobacco, Tea, Coffee, the Vine, &c., sufficiently show this; nevertheless, hereditarily, as they say in Hindostan; is *veri chív* (a great thing); and it has often happened that a plant retains its good qualities in the country and soil of its adoption. Then what is the use of man's intelligence if, having once got hold of a good plant he cannot make it stick to its character, or even improve it? We know that the Tomato in England is now a "how-is-it-never-did-without-it" sort of both fruit and vegetable. The Aubergine ought, likewise, to hold in time a similar position as an adopted vegetable.

It is not impossible that such a fine thing has not taken the fancy of English growers because they have not hit off the right way of cooking it, although Anglo-Indian housewives must know a good deal about the way of managing it for the table; but they would like to find it in the shops at a reasonable price. I fancy it would admit of being grown in pots in summer, under glass, exactly as the Tomato is grown.

For the benefit of those who may happen to grow the plants of the purple variety, I herewith give one of a dozen ways of cooking the Aubergine. In India, they have many varieties, some of them almost black, and as long and thin as Cucumbers; but the best I have ever tried is the Mároo Báingau of Delhi.

The rule is, first to "catch the best hare you can find." The stalk and calyx should be cut off, then the Aubergine sliced longitudinally, each slice of the thickness of about a quarter of an inch. Place them flat on a table or board, sprinkle salt over them, place another board on the top of them, and some weights on that. The object of all this is to drain off, by the help of the salt, the bitter juice which some kinds contain. I do not think the Delhi variety needs this trouble. Then wash off the salt, dry the slices in a cloth, and fry them in lard, or any other frying material. In Italy, they fry them in plenty of Olive oil (probably now they do it in Cotton-seed oil). In the olden time they used to call these fried slices of Aubergine, "quaglio" (quails), probably because they thought them delicious. Sometimes after drying in a cloth they are powdered with flour, which, when fried of a golden-brown, gives them a crumbly appearance. Done in this way, they can be eaten with meat, or, French fashion, as a separate dish.

There are many other ways of cooking the Aubergine. Roasted, or boiled and peeled, and then squeezed in a cloth, they may be used in curries, in omelets, &c. They can be stuffed with force-meat and baked, and in several other ways, but as this is not a paper on culinary subjects, I shall end by stating that English growers and English cooks will be unwise if they do not take to the Mároo Báingau of Delhi.—E. B.—*Gardeners' Chronicle*.

TASMANIAN APPLES.

"There is a glut of Apples in the market," said a morning contemporary, the other day; and "the Canadian crop of Apples is this year estimated at a million barrels," an evening journal had previously stated. All this, of course, writes a correspondent, means a bad lookout for low-class English products—first-class will always hold their own anywhere; and in those few words the grower may read his lesson. As time goes on, all the weedy sorts will have been cleared from the market, and Apples worthy of the name will be "worth money," as the saying is. By the month of March next, people will begin to sigh for a toothsome and clearer Apple, and then—on come the beautiful varieties from Hobart, in far Tasmania. We have been threatened with supplies from Australia; they would be very welcome, but they have yet to be grown, and it is just possible that Australia is not an Apple-growing country. This, however, from all accounts, Tasmania is; we can readily take this for granted, with the vivid memory of what has reached us from that far-off British colony, rapidly rising into importance, for much of which it is indebted to its Fruit-Growers' Association, and the Agent-General, located in the Broadway, Westminster—a gentleman with a firm belief in the future of his country, and quite able to direct the operations of those of his friends at the Antipodes who seek to find favour for their wares in the English markets. A pleasant interview with this gentleman a few days since was productive of much information concerning the Apples of Tasmania, from which we reproduce the following, almost in the words of our informant.

Three years since, the import of Apples into this country from Hobart was some 30,000 bushels; in the year following—1890—the figures had risen to 40,000; this year the importations had risen to 140,000 bushels! It may be stated here that during the season of 1891 considerable space was secured in the cool chambers of steamers loading fruit at Hobart beyond the first-class fruit then at the disposal of the shippers. To save absolute loss of freight, inferior fruit was shipped, with the consequence that the price fell from the average of 16s to 18s per bushel of 1889 and 1890 to 8s to 10s in 1891. It has been stated in the English press that the Tasmanian growers are satisfied with this lower rate; but they are not satisfied. The actual cost to the shipper in freight, &c., excluding the price of the fruit, is over 7s a bushel, and the 1s to 3s remaining over is less than the price which can be realised in the colony. The Government have noticed the mistake of putting anything but first class fruit on the English market, and there is no probability that the Tasmanian Fruit Growers' Association, which conducts the fruit exports, will allow such a blunder to be repeated. In the season of 1892 and thereafter, the British public need not anticipate the arrival from Tasmania of any but first-class apples.

Respecting the area over which apples are grown in Tasmania, the Agent-General informed us that the acreage under gardens and orchards in 1889-90 was 9803, against 6459 in 1880-81, and this increase is likely to be maintained. It is anticipated, says our informant, that in ten years hence the acreage will be extended to some 12,000 acres. To our thinking the increase will be greater. Our informant hinted at the possibility of an early start in the production of Peaches and Apricots for this market; certainly the fruit would be eagerly bought up if in good condition; and here, surely, what has been done may fairly be accepted as an earnest of what remains to be accomplished.—*Gardeners' Chronicle*.

NATURAL REPRODUCTION IN THE MADRAS FORESTS.
